# Infrastructure Operations

Use **VCF Operations** as a VI administrator to optimize and monitor compute, storage, and network of your VCF platform. These operational capabilities include performance optimization, visibility and observability of infrastructure and operations, global configuration management, monitoring, troubleshooting, log analytics, end-to-end network monitoring, energy efficiency monitoring, and other.

**In This Chapter**

- Integrating Data Sources with VCF Operations
- Configuring and Managing Policies
- Configuring Alerts and Using Actions
- Managing Inventory
- Configuring Automation Jobs
- Configuring and Analyzing Logs
- Network Operations
- Monitoring Storage Operations
- Using VCF Operations Diagnostics
- Troubleshooting with the Workbench
- Configuring Green Score
- Configuring Dashboards and Widgets
- Using Predefined Dashboards for Quick Insights
- Configuring Reports and Views
- Configuring Super Metrics
- Configuring Administration Settings
- Viewing Metrics and Properties
- Extending Monitoring Capabilities

**Getting to Know VCF**

To apply this documentation, you must be acquainted with the VCF Product Overview, VCF Design, and VCF Release Notes.

**SDKs, APIs, and CLI for VCF Administration**

You can build, operate, and manage your VCF private cloud by using the VCF SDK and APIs, and VCF PowerCLI. See Administration SDKs, APIs, and CLI.

## Integrating Data Sources with VCF Operations

You can extend the monitoring capabilities of VCF Operations by installing and configuring integrations in VCF Operations to connect to and analyze data from external data sources in your environment. Once connected, you can use VCF Operations to monitor and manage objects in your environment. These integrations are also referenced as management packs.

An integration can be a connection to a data source, or include predefined dashboards, widgets, alerts, and views.

Integrations include accounts, dashboards, reports, alerts, and other content. The accounts comprise of adapters, using which VCF Operations manages communication and integration with other products, applications, and functions. When an integration is installed and the accounts are configured, you can use the VCF Operations analytics and alerting tools to manage the objects in your environment.

VMware integrations include native, non-native, and external management packs.

For a new deployment of VCF Operations, the status of integrations is as follows:

**Table 1174: Integration Activation Status**

| Integration Name | Activated by Default? | Can be Deactivated? |
|---|---|---|
| vCenter | Yes | No |
| VMware Cloud Foundation | Yes | Yes |
| vSphere Supervisor | Yes | No |
| VCF for vSphere Replication | Yes | Yes |
| vSAN | Yes | No |
| Service Discovery | Yes | No |
| VCF Automation for VM Apps Organization | No | Yes |
| VCF Automation for All Apps Organization | No | Yes |
| OS and Application Monitoring | Yes | No |
| VCF for Networks | No | Yes |
| NSX | Yes | No |
| Ping | No | Yes |
| PCI Compliance | No | Yes |
| ISO Compliance | No | Yes |
| HIPAA Compliance | No | Yes |
| FISMA Compliance | No | Yes |
| DISA Compliance | No | Yes |
| CIS Compliance | No | Yes |

The list of activated and available integrations, accounts, and the full repository of integrations are all available from a central **Integrations** page in VCF Operations . This page can be accessed from the left menu by clicking **Operate** > **Administration** > **Integrations** > **Repository**.

### Non-Native Management Packs and Management Pack Builder

If a technology has no native management pack, you can install a non-native pack or can build your own using VCF Operations Management Pack Builder.

With the Management Pack Builder, you can create custom management packs for use in VCF Operations. This is a no-code solution for bringing in data from an external API and either creating new resources or extending your VMware and third party resources with new data, relationships, and events. For more information, see Management Pack Builder.

### Upgrade Considerations

The native integrations in VCF Operations are reinstalled if VCF Operations is upgraded.

## The Integrations Page in VCF Operations

You can activate integrations, install integrations, add, import, or export accounts from the **Integrations** page in VCF Operations. Integrations are also referenced as Management Packs in VCF Operations.

### How Integrations Work

Each account contains adapters using which VCF Operations integrates with other products, applications, and monitors their function and health. Integrations can include dashboards, reports, alerts, and accounts.

### Where You Find Integrations

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. By default, the **Accounts** tab opens. Use this tab to add, import, or export accounts. For more information, see The Accounts Tab.

Click the **Repository** tab to view the installed and available integrations. You can also install integrations that are delivered as PAK files. For more information, see The Repository Tab.

Click the **Solutions Catalog** tab to add and manage VCF Operations management packs from VCF Solutions Catalog. For more information see, The Solutions Catalog Tab.

> **Note:**
> For more information on pre-activated integrations, see Integrating Data Sources with VCF Operations.

### Collection Notifications

The **Notifications** bell icon on the top menu provides quick access to status and critical notifications that are related to data collections. The icon indicates whether notifications exist, and whether any of them are critical.

The list displays notifications about the data collections that are in progress, and indicates whether any of them have critical issues. The list groups the data collection notifications that are in progress into a single entry at the bottom of the list. To view the details about a collection, expand the notification.

Each notification displays the status of the last or current data collection, the associated adapter instance, and the time since the collection completed or an issue was identified. You can click a notification to open the **Integrations** page, where you can see further details, and manage adapter instances.

If problems occur with the data collections, VCF Operations identifies those problems during each 5-minute collection cycle.

Go to **Collection Status** to monitor the data collection, for more information, see Monitoring Data Collection .

## The Accounts Tab

You can view and add accounts from the **Accounts** tab on the Integration page in VCF Operations. You can add accounts for integrations or you can add accounts after activating integrations from the **Repository** tab.

### Where You Find the Accounts tab

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. The **Accounts** tab opens by default. The accounts tab lists all the accounts that are configured for the different integrations available in VCF Operations. You can filter accounts to view accounts specific to an integration type.

### What You Can Do in the Accounts tab

You can add and configure accounts that are associated with integrations that are pre-activated or those that you activate in VCF Operations . After you have configured the account, VCF Operations can collect data from or can send data to the target system. You can access the accounts page at any time to modify your adapter configurations.

**Table 1175: Accounts Page Options**

| Option | Description |
|---|---|
| Add | Click **Add** to configure new accounts for integrations. Click **Yes** in the **Installation Required** wizard if the integration is not installed. For more information on integrations, see Integrating Data Sources with VCF Operations.<br><br>**Note:**<br>You can also activate the integration from the Repository page and then add an account from the Accounts tab. For more information on activating available integrations from the Repository tab, see The Repository Tab. |
| Horizontal Ellipses | As a VCF Operations admin, you can back up the adapter configurations before upgrading. Click the horizontal ellipses and then click **Export** to export all the adapter configurations. To import them into a different VCF Operations instance, click **Import**. For more information, see Exporting and Importing Accounts. |
| Collection Status | View the overview of the data that is being collected at the cluster level in VCF Operations. |
| Credentials | You can configure or reconfigure credentials that you use to activate an adapter instance in VCF Operations. For more information, see Configuring Credentials in Integrations. |

After configuring accounts, you can view the account details and can edit them in the **Accounts** page.

**Table 1176: Accounts Grid Options**

| | |
|---|---|
| Vertical Ellipses | To view specific account details, expand the account type. Click the **>** icon on the left of the account and then click the vertical ellipses to change the account configurations.<br><br>• **Edit**: Allows you to edit the integrated adapter instance.<br>• **Delete**: Removes the adapter instance and clears the objects associated with the instance from the system, including historical data and role assignments.<br><br>**Note:**<br><br>When you delete an account, you can choose to delete any related objects by selecting the checkbox, **Delete related objects**. If you do not wish to delete the related objects immediately, leave the check box unselected. The related objects are kept in the inventory for the duration of the retention period specified in the **Global Settings** page. If you recover an adapter instance before the end of the retention period, the related objects are unmarked and not deleted.<br>• **Delete All**: Available for adapter instances with multiple sub-adapter configurations (such as the vCenter adapter). It removes the adapter instance along with its child adapter instances.<br><br>**Note:**<br><br>When you delete an account, you can choose to delete any related objects by selecting the checkbox, **Delete related objects**. If you do not wish to delete the related objects immediately, leave the check box unselected. The related objects are kept in the inventory for the duration of the retention period specified in the **Global Settings** page. If you recover an adapter instance before the end of the retention period, the related objects are unmarked and not deleted.<br>• **Start/ Stop Collecting**: Starts or Stops the data collection process.<br>• **Start/ Stop Collecting All**: Available for adapter instances with multiple sub-adapter configurations (such as the vCenter adapter). It starts or stops the data collection process of the adapter instance along with its child adapter instances.<br>• **Go to details**: Open the object in the object browser. |
| Name | Name that the vendor or manufacturer gave to the solution. |

| | |
|---|---|
| Status | Indicates the status of the solution and whether the adapter is collecting any data.<br>• Not Started: The adapter is not ready for data collection.<br>• Not Applicable: Data monitoring is not supported for the license that is applied to the adapter.<br>• Collecting: The adapter is ready for data collection.<br>• Warning: There is an issue that needs attention. |
| Description | Indicates what the solution monitors or what data source its adapter connects to. |
| Managed by VCF Operations | This column applies only to vCenter accounts including the ones under VCF domains. It displays the IP of the VCF Operations managing the adapter instance or "current instance" if the adapter instance is managed by the current VCF Operations instance. |
| Collector | Shows which VCF Operations node or VCF Operations collector appliance is collecting the data for the adapter. |
| Version | This column applies only to vCenter and VMware Cloud Foundation accounts. It indicates the version of the adapter instance. |

**Adding Accounts**

You can add and configure accounts associated with integrations that are provided with or that you add to VCF Operations. After you have configured the account, VCF Operations can communicate with the target system. You can access the **Accounts** tab in the **Integrations** page at any time to modify your adapter configurations.

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. In the Accounts tab, click **Add** and select the integration you want to manage. Configure cloud proxies and activate the integration before adding and configuring accounts. For more information, see Add a Cloud Proxy and The Repository Tab.

## Exporting and Importing Accounts

As a VCF Operations admin, you can back up the adapter configurations before upgrading, export all the adapter configurations, and import them into a different VCF Operations instance.

> **Note:**
>
> Users with "Export" permission can export and users with "Import" permission can import the adapter configurations. For more information, see Access Control: Roles Tab.

1. Export the adapter configuration.

   > **Note:**
   >
   > You cannot export default VMware Cloud Foundation and vCenter accounts that were configured in VCF Operations using the VCF Installer.

   a) In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**.
   b) In the Accounts tab, select the adapter configuration(s) that you want to export, click the horizontal ellipses, and select **Export**.
   c) Set up a new password to export data. The password should be at least 14 characters long and must include at least one numerical character, upper and lower case character, and special character.
   d) Click **Export**.

   The adapter configurations are exported in .zip format. A password is used to encrypt the data. Use the same password while importing this file.

2. Import the adapter configuration.

   > **Note:**
   > Before importing the content, ensure that you have exported the adapter configurations.

a) In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**.
b) Click the horizontal ellipses and select **Import**.
c) Click **Browse** to select the `.zip` file and enter the password that you had set while exporting the content.
d) If there is a conflict while importing the adapter configurations, you can either overwrite the existing adapter configurations or skip the import, which is the default option.
e) Click **Import** to import adapter configurations to the destination setup.

## Configuring Credentials in Integrations

Credentials are the user accounts that VCF Operations uses to activate one or more integrations and associated adapters, and to establish communication with the target data sources. The credentials are supplied when you configure each adapter. You can create new credentials and modify the credential settings outside the adapter configuration or during adapter configuration to accommodate changes to your environment.

If you are modifying credentials to accommodate changes based on your password policy, you must validate your connection so that the adapters configured with these credentials begin using the new user name and password to communicate between VCF Operations and the target system.

To edit credential settings, from the left menu, click **Administration** > **Integrations**. In the Accounts tab, click **Credentials** .

By default, the Credential Ownership Enforcement option is activated. When this option is activated, you can view, add, modify, or delete only the credentials that you created or that were assigned to you. You can view and use unassigned credentials only if you have the required permissions. You can also deactivate the **Credential Ownership Enforcement** option from **Global Settings** page to be able to modify credentials created and owned by others. For more information, see List of Global Settings.

### Where You Find Credentials

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. In the **Accounts** tab, click **Credentials**.

**Table 1177: Credentials Options**

| Option | Description |
|---|---|
| Toolbar options | Manages the selected credential.<br>• **Add**: Adds new credentials for an adapter type that you can later apply when configuring an adapter. For more information, see Adding Credentials. |
| Edit/Delete credentials | • Click the **Vertical Ellipses** to perform any one of the following actions on existing credentials:<br>– **Edit**: Modifies the selected credentials, usually when the user name and password require a change. The change is applied to the current adapter credentials after you validate the connection and the data source continues to communicate with VCF Operations.<br>– **Delete**: Removes the selected credentials from VCF Operations. Commonly used to delete misconfigured credentials. You cannot delete a credential in active use. To remove it, first reconfigure or delete the adapter, then delete the credential. |

### Adding Credentials

To configure or reconfigure credentials that you use to activate an adapter instance, you must provide the collection configuration settings, for the target system. You can also modify the connection settings for an existing credential instance.

### Where You add Credentials

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. In the **Accounts** tab, click **Credentials**, and then click **Add**. The **Manage Credentials** dialog box opens.

### Manage Credentials Options

The **Manage Credentials** dialog box is used to add new or modify existing adapter credentials. The dialog box varies depending on the type of adapter and whether you are adding or editing. The following options describe the basic options. Depending on the adapter instance, the options other than the basic ones vary.

**Table 1178: Manage Credential Add or Edit Options**

| Option | Description |
|---|---|
| Adapter Type | Adapter type for which you are configuring the credentials. |
| Credential Kind | Credentials associated with the adapter. Some adapters support multiple types of credentials. For example, one type can define a user name and password, and another can define a pass code and key phrase. The combination of adapter and credential type affects the additional configuration options. |
| Credential Name | Descriptive user-defined name that you provide to manage the credentials. Not the account user name. |
| User Name | User account credentials that are used in the adapter configuration to connect VCF Operations to the target system. |
| Password | Password for the provided credentials. |

## The Repository Tab

The repository tab lists all the installed and available integrations in VCF Operations. Integrations are also referenced as Management Packs and Solutions.

### Where You Find the Repository Tab

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**, and then click the **Repository** tab. The page displays installed and available integrations as clickable cards.

### What Can You Do in the Repository Tab

In the **Repository** tab, when you click an integration card, the details page is displayed.

The management pack details page consists of the following three tabs:

- Overview: Describes the management pack and its purpose.
- Metrics: Displays a list of metrics and properties for the various object types as defined by the adapter.

  **Note:**

  This list of metrics and properties can display additional metrics and properties after account creation since other sources can also publish them.

  The actual list of published metrics and properties depends from policy customization and monitored environment.
- Content: Displays the content types and the data defined by that management pack.

**Table 1179: Management Pack Details Page Options**

| Options | Descriptions |
|---|---|
| Name | Name of the management pack, the name of the vendor or manufacturer who created the management pack, and version number. |
| Activate | Installs the management pack. You can configure cloud management packs after activation from the **Repository** or **Accounts** tab of the **Integrations** page.<br>The activation starts only if all the cluster's nodes are accessible.<br>**Note:**<br>Some of the pre-installed management packs are activated by default. You can configure them from the **Management Pack Details** page or the **Accounts** tab of the **Integrations** page |
| Add Account | The add account button is available only after the management pack is activated. For more information on the accounts which are activated by default, see, Integrating Data Sources with VCF Operations. |
| **Horizontal Ellipses** > **Reset Default Content** | This option is only available for the vCenter management pack.<br>After you update your instance of VCF Operations and select the Reset Default Content option, the existing default alert definitions and symptom definitions are overwritten with the newer versions from the update. This includes your existing compliance alert definitions.<br>**Note:**<br>Clone any customized content before you proceed, because a reset overwrites user modifications. |
| **Horizontal Ellipses** > **Deactivate** | You can uninstall a particular integration with its associated data, metadata, and the out of the box content. Select **I understand the risk and agree** to uninstall an integration. |
| **Horizontal Ellipses** > **Upgrade** | Acter you activate a management pack, if an upgrade is available, you can upgrade it to its latest version. To do so, select the select the management pack, click the horizontal ellipsis, and then click **Upgrade**. |

## Adding a Management Pack

Management packs are delivered as PAK files that you upload, license, and install.

### How Management Packs Work

When you add a management pack, you configure adapters that manage the communication and integration between VCF Operations and other products, applications, and functionality.

### Where You Add Management Packs

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. Click the **Repository** tab and then click **Add** to install other management packs.

### Add Solutions Wizard Options

The wizard includes three pages where you locate and upload a PAK file, accept the EULA and install, and review the installation.

Before you install the PAK file, or upgrade your VCF Operations instance, clone any customized content to preserve it. Customized content can include alert definitions, symptom definitions, recommendations, and views. While upgrading to the latest version, you can select the **Install the PAK file even if it is already installed** and the **Reset Default Content** options.

**Table 1180: Wizard Options**

| Option | Description |
|---|---|
| Page 1 | |
| Select a Management pack to install | Navigate to your copy of a management pack PAK file. |
| Download Management Pack | When you click **Get** in the **Repository** page, the management pack is automatically downloaded. You can view the Name, Description, and Version of the management pack that is installed. |
| Upload | To stage the management pack for installation, copy the PAK file to VCF Operations. |
| Install the PAK file even if it is already installed | If the PAK file was already uploaded, reload the PAK file using the current file, but leave user customization in place. Do not overwrite or update the solution alerts, symptoms, recommendations, and policies. |
| The PAK file is unsigned | A warning appears if the PAK file is not signed with a digital signature that VMware provides. The digital signature indicates the original developer or publisher and provides the authenticity of the management pack. If installing a PAK file from an untrusted source is a concern, confirm that the management pack is signed and certified with the management pack distributor before proceeding with the installation. |
| Page 2 | |
| I accept the terms of the agreement | Read and agree to the end-user license agreement.<br>**Note:**<br>Click **Next** to install the management pack. The installation starts only if the VCF Operations cluster is online and all the nodes in the cluster are accessible. |
| Page 3 | |
| Installation Details | Review the installation progress, including the VCF Operations nodes where the adapter was installed. |

## The Solutions Catalog Tab

You can add, manage, create, and download management packs in the Solutions Catalog tab in VCF Operations.

### About Solutions Catalog

You can use the Solutions Catalog to discover and deploy curated, trusted, and certified solutions in your VCF environment. From the Solutions Catalog tab, you can:

- View and download available management packs from VCF Solutions Catalog.
- Upload management packs .zip files in VCF Operations.
- Install, upgrade, or delete downloaded or uploaded management packs.
- Create custom management packs in VCF Operations.

If your VCF Operations instance is able to connect to VCF Solutions Catalog (requires outbound Internet connectivity from VCF Operations), you can view, download, and install available management packs in the Solutions Catalog tab. For more information, see Adding Management Packs from Solutions Catalog in Connected Mode.

If your VCF Operations instance cannot connect to VCF Solutions Catalog, you can manually upload management pack .zip files in the Solutions Catalog tab. For more information, see Adding Management Packs from Solutions Catalog in Disconnected Mode.

If you want to create a custom management pack in VCF Operations, click **Create Management Pack** on the Solutions Catalog tab to create one. Once done, you can install it in VCF Operations. For more information, see Management Pack Builder.

**Migrating Management Packs**

When you upgrade to VCF 9.1 from a prior version of VCF Operations, the upgrade migrates the installed management packs.

- Migration Status**:**
  - Only installed management packs are migrated.
  - Downloaded but not installed management packs are removed. They must be re-downloaded and installed after the upgrade.
- Post-Migration Limitation**:**
  - You cannot view the **Content** and **Resource & Support** tabs for migrated management packs.
- Disconnected Mode:
  - If VCF Operations is upgraded in disconnected mode, the icons for the migrated management packs will not be displayed. To resolve this, you must switch to connected mode and either manually sync the management pack inventories or wait for the scheduled sync which runs every 12 hours.

## Adding Management Packs from Solutions Catalog in Connected Mode

If your VCF Operations instance is in connected mode, you can view and download available management packs in the Solution Catalog tab in VCF Operations.

If your VCF Operations instance can successfully sync with VCF Solutions Catalog, all available management packs that are associated with VCF Operations are displayed in the **Available** section of the Solutions Catalog tab.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, select **Administration** > **Integrations**, and then click the **Solutions Catalog** tab.
   a) (Optional) Select a management pack and click **View Details** and click the **Overview**, **Resource & Support**, and **Tasks** tabs to view the management pack details.

      **Note:**

      All actions performed on a management pack are displayed in the **Tasks** tab. You can review execution details for any task, and access the corresponding error logs in the event of a failure.

   On the **Solutions Catalog** tab, the **Available** section is displayed by default. All the management packs that are compatible with the current version of VCF Operations are displayed.
2. Use the version selector to view the available versions and then select the version you want.

   **Note:**

   Only compatible versions of the management pack are displayed in the version selector.
3. Click **Download**, accept the **EULA Agreement**, and then click **Download** again.

The management pack is downloaded in VCF Operations. All downloaded management packs are listed in the **Downloaded** section of the Solutions Catalog tab.

After you download a management pack in VCF Operations, you need to install it before you can use it. For more information, see Installing and Uninstalling a Management Pack from Solutions Catalog.

## Adding Management Packs from Solutions Catalog in Disconnected Mode

If your VCF Operations instance is in disconnected mode, you can download the management pack from VCF Solutions Catalog and then upload it manually in the Solution Catalog tab in VCF Operations.

If your VCF Operations instance is unable to connect to VCF Solutions Catalog, no management pack will be displayed in the **Available** section of the **Solutions Catalog** tab. In such cases, you can manually download management packs and then upload them in VCF Operations. Optionally you can also upload a management pack that is not available in the Solutions Catalog.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, select **Administration** > **Integrations**, and then click the **Solutions Catalog** tab.
2. On the **Solutions Catalog** tab, click the VCF Solutions Catalog link to open the VCF Solutions Catalog webpage.
3. Manually download the desired management pack for VCF Operations. For more information, see VCF Solutions Catalog Overview.
   a) Log in to VCF Solutions Catalog webpage and then click **Download for VCF-OPS** to download the management pack .zip file.
   b) Enter the **Key**.

      The Key is the asset key that is used when you download the management pack PAK file from VCF Solutions Catalog.

      The management pack .zip file is downloaded.
4. Unzip the management pack .zip file, return to the **Solutions Catalog** tab, and then click **Upload**.
5. Browse and select the management pack .zip file and then enter the **Key**.

   You must enter the same key that you entered at the time of download.

The management pack is uploaded in VCF Operations. All uploaded management packs are listed in the **Downloaded** section of the Solutions Catalog tab.

After you upload a management pack in VCF Operations, you must install it. For more information, see Installing and Uninstalling a Management Pack from Solutions Catalog.

### Installing and Uninstalling a Management Pack from Solutions Catalog

After downloading or uploading a management pack in VCF Operations, you must install it.

- Ensure you have downloaded or uploaded the management pack you want to install. For more information, see Adding Management Packs from Solutions Catalog in Connected Mode and Adding Management Packs from Solutions Catalog in Disconnected Mode.

To use a management pack, you must install it.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, select **Administration** > **Integrations**, and then click the **Solutions Catalog** tab.
2. Click **Downloaded** to open the **Downloaded** section to see the list of management packs that have been downloaded from the solutions catalog.
3. Locate the management pack you want to install and click **View Details**.
   a) (Optional) Click the **Overview**, **Metrics**, **Content**, **Resource & Support**, and **Tasks** tabs to review the management pack details.

      **Note:**

      Management packs that were downloaded but not installed before an upgrade are not migrated. If a previously downloaded management pack does not appear on this page after upgrading to VCF 9.1, you must download it again.
4. 
5. Click **Install**, verify the **Component Confirmation**, and then click **Install** again.

   The management pack is installed.

6. Optional: Click **Sync Installed Solution** to sync the management pack inventories on demand. By default, the inventory in the VCF Operations **Repository** tab is synced with the VCF Solutions Catalog page every 12 hours.
7. Optional: Click **Check for Updates** to check for upgrades to previously downloaded management packs.

   If an update is available for any management pack, the **Upgrade** button will become active, allowing you to download the newer version. Upgrading a management pack will overwrite the old version's content with the new version's content.
8. Optional: You can uninstall or delete a management pack that is no longer required. Uninstalling or deleting a management pack, automatically deletes its associated accounts.
   - Uninstall: Removes an installed management pack from the environment and moves it back to the **Available** section of the Solutions Catalog tab, where it can be installed again. Locate the management pack you want to uninstall and click **Uninstall**. Confirm that you want to uninstall the management pack, and then click **Uninstall** again. The management pack is uninstalled.
   - Delete: Permanently removes a management pack from the Solutions Catalog. Before you can delete a management pack, you must first uninstall it. Locate the management pack you want to delete and click **Delete**. Confirm that you want to delete the management pack, and then click **Delete** again. The management pack is deleted.

All installed management packs are displayed on the **Administration** > **Integrations** > **Repository** tab. After installation, you must add accounts for each management pack. Each account contains adapters using which VCF Operations integrates with the management pack and monitors their function and health. For more details, see The Repository Tab.

If you delete a management pack from the respository page, only the management pack icon is removed from the solutions catalog page. To remove the management pack completely from the solutions catalog page, either manually sync the management pack inventories or wait for the scheduled sync which runs every 12 hours.

## Management Pack Builder

The Management Pack Builder enables the creation of custom management packs for use in VCF Operations. This is a no-code solution for bringing in data from an external API and either creating new resources or extending VCF Operations and third party objects with new data, relationships, and events.

### Backwards Compatibility

In VCF Operations, there is no separate installation required. Previously, you needed to deploy a separate OVA virtual appliance, which involved extra setup steps. Now, it is pre-integrated into the VCF Operations platform, reducing the initial installation time and eliminating compatibility issues.

The Management Pack Builder retains backward compatibility. Existing designs can be imported directly, preserving previous work while leveraging new efficiencies and improved performance. This ensures a smooth transition for teams who previously relied on the standalone Management Pack Builder.

### Where you find the Management Pack Builder

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Developer Center** > **Management Pack Builder**.

### What Can You Do in the Management Pack Builder page

You can use the **Management Pack Builder** page to design a new management pack, import or export a design, edit an existing design, or delete an existing design. After you design a management pack, you can install it.

**Table 1181: Accounts Page Options**

| Option | Description |
|---|---|
| Create New | To create a new management pack, you must perform the following steps:<br>• Connect: Connect to a data source to collect data.<br>• Transform: Use the data from the connected source to define the VCF Operations objects.<br>• Verify: Review and validate the management pack design.<br>• Install: Install the management pack.<br>To create a new management pack, click **Create New**, enter the **Name** and **Description**, and select the **Type**. You cannot change the management pack type after you create it.<br>**HTTP API**: Use the HTTP API type to create a management pack that collects data from an HTTP API to create objects, relationships, and events in VCF Operations. To design a management pack using HTTP, see Designing a Management Pack using HTTP.<br>**Prometheus**: Use the Prometheus type to create a management pack that collects data from Prometheus which includes objects and relationships. To design a management pack using Prometheus, see Designing a Management Pack using Prometheus. |
| Import Design | If you do not have any designs, you can import a JSON design file in VCF Operations. For more information, see Importing or Exporting a Design. |

After you create or import a design, you can view, export, edit, or delete it in the **Management Pack Builder** page.

**Table 1182: Designs Grid Options**

| Option | Description |
|---|---|
| Design | Displays the name of the design. |
| Type | Displays the design type: HTTP API or Prometheus. |
| Design Status | Indicates the status of the design.<br>• Valid: The design contains all components required to create a management pack. It has not been tested using the "Verify" step.<br>• Invalid: The design has an issue that needs to be resolved before it can be tested and installed.<br>• Verified: The design contains all components required to create a management pack and the "Verify" step has run successfully.<br>• Incomplete: The design does not contain all the components needed to create a management pack. |
| Install Status | Indicates installation status of the design.<br>• Installed<br>• Uninstalled<br>• Draft<br>• Out of date |
| Last Edited | Indicates when the design was last modified. |
| Edit | Click a design to edit it. |
| Export | Export a design as a JSON file. For more information, see Importing or Exporting a Design. |
| Delete | Delete the design. |

## Before you Start your Design

Before starting, you should make sure you have access to the reference environment including hostname, user information, and API documentation. It is important to think about what you want to include in it. The main items to understand are objects, requests, and relationships.

**Things to Consider for designing a Management Pack using HTTP**

- Objects: Objects are the core item that we will be adding or updating in VCF Operations . You should think of them as the nouns of your technology. An example is a network switch. Your nouns for a switch could be the switch, ports, CPUs, and fans. These would all become objects in your design. For every object, you will provide the metrics and properties by adding one or more requests. VCF Operations manages metrics by the objects and has limits based on number of objects and metrics. Please review the sizing guide for the appropriate sizing of VCF Operations when designing your objects.

  You can also extend existing objects in your VCF Operations environment such as VMs, Host Systems, or third-party resources. By extending those objects, you can add metrics or properties to the existing object allowing custom information to be used as if it was part of the original resource.

  **Note:**

  VCF Operations manages metrics by objects and imposes limits based on the number of objects.

- Requests: These are the API requests used to add metrics and properties. To understand what is available on these requests, reference the API documentation. In our switch example, the requests to create port objects could include an interface endpoint that lists all the ports and a stats endpoint that show the performance of the port.
- Relationships: Relationships associate objects to each other in a parent to child relationship. This creates a topology for your objects allowing VCF Operations to understand the connectivity between your objects. In our switch example, the switch would be the parent to the ports, CPUs, and fans. You can also add relationships to VCF Operations objects like hosts, VMs, or third-party resources like data arrays.
- Events: Events represent a message reported by your endpoint pertaining to a VCF Operations object with an associated severity. Events can be used to impact the health of an object using symptoms. These symptoms also can be used to create alerts.

**Things to Consider for designing a Management Pack using Prometheus**

- Objects: Objects are the core item that we will be adding or updating in VCF Operations. You should think of them as the nouns of your technology. In a Prometheus design, objects are associated with a specific Prometheus job. For every object type, you will select the Prometheus metrics you would like to include and the labels on those metrics which will be mapped to identifiers and properties on the object. VCF Operations manages metrics by the objects and has limits based on number of objects and metrics. Please review the sizing guide for the appropriate sizing of VCF Operations when designing your objects.

  You can also extend existing objects in your environment such as VMs, Host Systems, or third-party resources. By extending those objects, you can add metrics and properties to the existing object, allowing custom information to be used as if it was part of the original resource.

  **Note:**

  VCF Operations manages metrics by objects and imposes limits based on the number of objects.

- Relationships: Relationships associate objects to each other in a parent to child relationship. This creates a topology for your objects allowing VCF Operations to understand the connectivity between your objects. You can also add relationships to objects like hosts, VMs, or third-party resources.

**Creating A Regular Expression**

A regular expression is a sequence of characters that define a search pattern, mainly for use in string matching. Management Pack Builder supports Java-style regular expressions. When using a **Regular Expression** in Management Pack Builder you can enter in the expression in the **Regex** field. When the test button is pressed the **Sample Value** will be run through the expression and the result will be displayed in the **Sample Output**.

Regular expressions can be used in the following contexts:

- When defining fields that should match between objects when creating a relationship.
- When defining fields that should match between an event and the object it could be assigned to when creating an event.

**Variables**
Custom authentication allows the user to add custom variables to be used in the advanced section of the source creation. This is generally used with permanent session tokens, or any variable sent with every request.

## Designing a Management Pack using HTTP

VCF Operations offers a wizard that makes it easy for you to design a management pack based on an HTTP API.

Building a new HTTP API-based management pack consists of the following steps. Once you start your design, you can save your work and pick up from where you left off. You can edit an existing design at any step.

- Define a Data Source: In this initial step, you define the data source from which the management pack will collect information. This involves specifying the external API or system that the management pack will integrate with, setting up the necessary connection parameters, and ensuring that the data source is accessible for data retrieval.
- Set up API Requests: Here, you configure the specific API requests or queries that will be used to fetch data from the defined source. This includes detailing the endpoints, request methods, parameters, and any necessary authentication details to ensure successful data extraction.
- Define Objects: In this step, you define the objects that represent the data entities retrieved from the source. This involves mapping the data to meaningful resource types within VCF Operations, specifying their properties, and determining how they will be represented in the monitoring environment.
- Specify Relationships (Optional): This step focuses on establishing relationships between the defined objects. By specifying how these objects interrelate, you can create a structured representation of the data, which aids in understanding dependencies and interactions within the monitored environment.
- Define Events (Optional): Here, you create an event from an API by defining the message, severity, and assoicated objects. You can configure symptoms and alerts for significant events in VCF Operations after designing the management pack.
- Verify your Design: In this step, you validate the configurations made in the previous steps. This involves testing the data collection, ensuring that objects and relationships are correctly defined, and confirming that events trigger as expected. It’s a crucial step to ensure the management pack functions as intended before deployment.
- Install: This is the final step. After you have reviewed and verified the design, you can install the management pack.

**Define a Source**
Start by identifying the source system or API from which you intend to pull data. This step includes specifying host name, connection settings, and authentication protocols.

**Sub-sections in Define Source**

- Data Source Connections
- Get Session (visible if you turn on session authentication)
- Global Settings
- Release Session (visible if you turn on session authentication)
- Test Connection

**Data Source Connections**

- Collector: The collector node or cloud proxy from which the Management Pack Builder adapter instance will make API requests during the design process.
- Host Name:The target you're pulling data from.
- Port:The port to use.
- TLS Configuration: Select from one of the following options:
  - Verify: Use TLS and verify the target's certificate
  - No Verify: Use TLS but don't verify the target's certificate
  - No TLS: Do not use TLS at all
- Base Path: Path to be added to all API calls defined in this design. You can leave it blank and use the full path for all requests if there is no shared prefix.

- Preview API Path: A preview of your full path.

**Authentication Details**

Configure the authentication details for your API requests.

Choose between basic authentication, custom authentication, and no authentication. The configuration here is used for every subsequent call, so you only need to configure authentication once. If you need to create a session token, before making connection requests, turn on **Use Session Authentication**.

The Management Pack Builder can use three different authentication source types:

- Basic: Specify a username and password. The header is automatically created.
  - Username: The user on reference system that is authorized to query the intended API endpoint.
  - Password: User's password for authentication.
- Custom**:** Add authentication fields and headers.
  - Use custom authentication when you need to add custom variables to be used in the advanced section of the source creation.
  - This is generally used with permanent session tokens or any variable sent with every request if session authentication is not used.
  - It is generally used for login credentials that will be used in POST a post body to get the session token when using session authenication.
- No Authentication**:** Use for public and non-secured APIs.

You can next choose to turn on **Session Authentication**. Session authentication is a method in which a session is created on login and stores information from the response body and/or headers as defined by the user. Common fields include a token or a session ID. When running a collection, the session fields are retrieved once, then used on all subsequent requests. If a release session request is defined, the session is released at the end of the collection.

Once you are done, click **NEXT**.

**Get Session**

Define the **HTTP Method** and **API Path** when using session authentication.

- HTTP Method: Based on the API requirements this will be either a GET, POST, PUT, PATCH.
- API Path: This is the path to the session creation resource as defined by the API documentation.

Next, set up additional request settings, such as headers, query parameters, and body

- HTTP Headers: This is used to assign headers to the request that is used to retrieve the session. This only needs to be used if the API requires custom values in the header. If using basic credentials, the Authorization header is automatically added and thus does not need further configuration.
- Query Parameters: This section allows the user to add custom query prompts to the end of the URL request. This is optional and only necessary if the API documentation calls for it.
- Body: This allows you to create a body to be sent to the session creation request. Some APIs require the body to contain information like user and password. This is optional and only needs to be used if the API documentation indicates it.

Click **Test** to see the test response. VCF Operations displays the **Body**, **Headers** and **Log**.

Once you are done, click **NEXT**.

**Global Settings**

Define the headers which are used to pass data with every call in the request header. Session data should be put here so that every call includes the session ID or token information.

Once you are done, click **NEXT**.

### Release Session

Defining a **Release Session Request** is recommended when using session authentication. This request will log out the session, reduce session leaks, and improve security.

- HTTP Method: Based on the API requirements this will be either a GET, POST, PUT, PATCH, DELETE.
- API Path: This is the path to the API endpoint you want to use to release the session.

Once you are done, click **NEXT**.

### Test Session

In this step, you to define the **HTTP Method** being used (GET, POST, PUT, PATCH), the API path, and see a preview of the fully qualified path. Then, you click **TEST CONNECTION**.

- HTTP Method: Based on the API requirements this will be either a GET, POST, PUT, PATCH.
- API Path: This is the path to test that your defined authentication works for your API.

The test connection confirms that all the source data is set up correctly. If using basic authentication, this will send one request including the basic authentication header. If using the session, this will make up to three requests to create the session, make a call to the test endpoint, then make a call to delete the session.

The response section will show the response to the test connection endpoint. You can see the body and headers of the response as well as the logs generated by the request. You can download the test response as a JSON file.

Once you are done, click **SAVE SOURCE**.

**Add Requests**
This is the second step of the wizard. You can add all the API calls used by the design to provide data to the objects and events. You will need to reference your API documentation to determine the endpoint and settings necessary for this section.

### Add API Request and API Pagination

In the **Add API Request** section, define the endpoint to be used for the request. Note: the source hostname, port, and base path will be prepended to this path for the request URL.

- HTTP Method: This is the method used for the request. It will be either a GET, PUT, PATCH, or POST.
- API Path: Endpoint that needs to be call to retrieve the data.
- Name: Name for this request used in future settings in the design.

Advanced (optional)

In this section you can add specific data to the requests body, headers, and query parameters, as defined by the API documentation.

Once you are done, click **SAVE REQUEST**.

You can also add paging to your API call in the **Add API Pagination** section. You must make the request prior to configuring paging. Management Pack Builder supports two main methods of pagination: offset and pages. Reference your API documentation to determine whether paging is necessary and, if so, which method to use.

- Paging Parameter: This is the parameter name to use to indicate which page we are requesting.
- Starting Offset: This is the number that represents the beginning of the API's results. Often, "Pages" start at 1 and "Offset" starts at 0. Confirm the starting number in the API documentation.
- Limit Parameter: This is the parameter name for the number of records per page.
- Limit Value: The number of records returned per page.
- Data List Returned from Paged Request: List of data being returned. When the count of this is less than the limit value, it means that the end of the data has been reached and no more paged requests will be made.

### Chain From Other API Calls

To add a chained request, return to the wizard, go to the **Requests** step, and select the parent request from requests list, then select **Add Chained**.

- In the **Add Chaining** section, select a list from the parent request's response which contains the attribute(s) to be used in the child request.
- System Attributes: For each attribute that you would like to use in the child request, select **Add Field**. Select the **Attribute**. If desired, update the **Parameter**. The **Parameter** will be used to define the usage key, so make sure that it is meaningful in the context of the design. If the parent request had a value for the selected attribute, it will populate by default. Regardless, you can manually set the value here. This is the value that will be substituted for the usage key later when testing the child request, so make sure that it is a valid value which will cause the child request to succeed.
- In the **Add API Request** section, define the child request like any other request, but now you can use the attribute(s) defined in the previous step. You can insert the usage key in the path, headers, query parameters, and/or body of the child request. To insert the attribute usage key, click the clipboard icon on the right side of the field, then select the attribute you want to insert. It will be inserted where the cursor is currently located in the field. When the request is run via **MAKE REQUEST**, all usage keys will be replaced with the sample values defined in the previous step.

Once you are done, click **SAVE REQUEST**.

**Add Objects**

In the third step, you define the objects that will be part of your custom management pack. You can define new objects or extend existing objects from VCF Operations with new metrics and properties.

**Sub-Sections in Add New and Add Existing Objects**

- Object Type
- Attributes from API
- Properties and Metrics
- Name and Identifiers (Section appears only when adding new objects.)
- Object Bindings (Section appears when there is an existing object or when the attribue selections require it)

**Object Type**

- Add New Object Type: The object type is the user-facing label that will be displayed for this type of object in VCF Operations when this management pack is installed. Example object types are Switch, Port, etc. You can also choose the icon that will be used in VCF Operations. Once you are done, click **NEXT**.
- Add Existing Object: To extend an existing object, choose a resource type to extend from the list of resource types on your VCF Operations instance. You can filter by the resource type or page through the list of available options.

**Attributes from API**

From the list of **Requests**, you select one or more requests to pull into this object. You will then select all the data entries you want to add to your object from the list. You can search the list of attributes for a specific attribute or scroll through the list.

Once you are done, click **NEXT**.

**Properties and Metrics**

Here you will see the metric and property definitions you have attached to the object.

- Label: The name of the metric or property visible in VCF Operations.
- Datatype: Defines how the data is rendered. If you select decimal or one of the counter options and the data cannot be converted to a number, the data will be discarded.
  - String: Returns the value of the attribute as a string. This datatype is allowed only on properties, and not metrics.
  - Decimal: Returns the value of the attribute as a number.
  - Counter Delta: Calculates the change in the value between collections.
  - Counter Rate: Calculates the change in value between collections over time.
- Unit: If applicable, this is where you can define the unit for the data point. This will allow auto-scaling in dashboards and reports.
- Property: This drop-down list indicates whether the data is a property.

- KPI: This toggle indicates whether the data will be treated as a KPI. KPIs are key metrics that are used in dashboards and resource detail pages. They should be metrics that are important to the status, performance, and health of the object.
- Expanded row view:
  - Request: Shows the call and data path from which this metric is pulled.
  - List: List in the request response from which the data is pulled.
  - Attribute: Name of the attribute in the response being pulled.
  - Example: Shows the value of the first returned data point from the request.

  Once you are done, click **NEXT**.

**Name and Identifiers**

Define the identity of the object in this step.

- Object Instance Name: This is the property from the list above that is used as the object's name in VCF Operations.
- Object Identifiers: Define the properties using the smallest set of properties that will accurately and uniquely identify each object.

Once you are done, click **SAVE OBJECT**. If you see Attribute Bindings, proceed to the next step.

**Attribute Bindings**

When combining data from multiple JSON or XML arrays into a single new object, it's necessary to establish a base array and select a corresponding attribute from each of the other arrays for mapping. You will only see this section if it is required.

When extending an existing object, all arrays must link to a property or identifier on the existing object in VCF Operations.

- API Attribute: The data from the selected JSON or XML list in the API response that you match to an existing property or identifier.
- Object Property: A matching property or identifier on the object. For a new object, it is selected from the base list. For an extended object, it is selected from the identifiers and properties of the existing object.

### Best Practices For Metrics and Properties

Follow these best practices when you create objects from new metrics and properties.

**Best Practices**

- Objects created from new metrics and properties should be represent stable objects, not transient objects.
- Metrics should represent measurable performance characteristics. Example: CPU Utilization %, Network Throughput, etc. Properties should represent relatively stable configuration values. Example: version, power status, etc.
- Properties should have a small number of possible values.
- Property values should not change frequently from collection to collection.
- Opt for defining metrics using reasonable unit sizes and prefix multipliers to avoid publishing excessively large values.
- The depth of the relationships of the objects should not be too deep (for example 100).
- Avoid defining artificial relationships that do not exist in the end-point.

### Define Object Relationships

Relationships are a parent to child connection that is used in VCF Operations to define the interaction between interconnected resources. Parent to child relationships are the only supported type of relationships with the Management Pack Builder.

**Parent and Child object**

Define the objects used to create the relationships. Parent objects are higher in the topology.

**Matching Properties**

Relationships in Management Pack Builder are created by matching all resources with matching properties. For example, a Switch has a **switch ID** property and the Port has a **parent switch ID** property. The parent object properties and the properties of any relevant child object(s) will always match, e.g. **switch ID** with **parent switch ID**. With multiple matching sets, all sets of properties must match for the relationship to be created. This can be either case-sensitive or insensitive and use basic or advanced matching.

Once you are done, click **SAVE RELATIONSHIP**.

**Add New Events**

Map events from the target system into the VCF Operations event model. This includes defining event triggers and mapping severity levels, and linking them to VCF Operations objects.

**Sub-sections in this step**

- Add Events from API
- Severity
- Related Objects

**Add Events from API**

- Event Name: The user-friendly name of the event. This will be prefixed on the event message in VCF Operations.
- API Request: This is the request endpoint setup in the **Requests** section to use to create events.
- Event List: The location of events in the API response.
- Event Message: This is the event message that will show in VCF Operations. Often in APIs this would be the event description. You can create the message using one or more fields from the response and type any static information as well. You can also edit the value of the fields using regular expressions. See the section on regular expressions for further help on this.
  Once you are done, click **NEXT**.

**Severity**

Events in VCF Operations are ranked with a severity from Info to Immediate. Please reference your API documentation for a list of valid severities they support.

- Event Severity: Define API response fields and static text which form the event severity definition. You can also adjust the value of the fields using regular expression.
- Map Severities: Add mappings from the VCF event severity (Event Severity) to the corresponding value expected from the API (API Response Severity). For example, if the API returns "critical," you would map to the VCF "Critical" severity. Sometimes an API will have a severity that does not directly correspond to a VCF severity. In that case, the mapping is up to your discretion. For example, if any API returns an event severity of Severe, you must map that to the VCF severity "Critical," or "Immediate."
- Set all unmatched API response Severities to: Specify a default severity. If an event severity is returned from the API that does not match one of the mappings you created, the associated event will be set to the default severity specified here.

Once you are done, click **NEXT**.

**Related Objects**

Relate events to objects by matching. Select "All" if you want to related events to more than one object in the case that multiple related objects match. Select "First" if you only want the first related object to match.

The order defined in this section is the order in which the management pack will evaluate matches.

Add related object: For each related object, first select the object type (**Select object**) to relate to. By default, you can choose any object types included in the current design. If you select "All objects", you can also choose from existing object types in VCF Operations. Next, create a mapping from the object properties to the API response. You can use any combination of object properties, API response fields, static text, and regular expressions to make the mapping work. In

the top-right, you can choose whether the matching logic should be case-sensitive. If you define multiple related objects and selected "Relate events to objects by matching: First", you can use the arrows on the left to change the order in which the mappings will be evaluated.

Once you are done, click **SAVE EVENT**.

#### Verify your Design

Before final deployment, you can test your design to ensure that the management pack collects the correct data and accurately represents the target system within VCF Operations.

#### Perform Collection

Click **PERFORM COLLECTION** to verify your design.

VCF Operations runs the collection and displays the following information:

- Summary: Displays the **Collection Status**, **Collection Time**, **Objects Collected**, **Metrics Collected**, **Properties Collected**, **Relationships Found**, and **Events Collected**.
- Log: Displays the last 1000 lines. You can download the log to view all the lines. You can change the logging level to see more detailed logs.
- Objects: Displays the details for the objects.
- Events: Displays the events for the objects.

Once you are done, go to the final step, **INSTALL**.

#### Install

Once testing is complete, click **REVIEW CONFIGURATION** or directly click **INSTALL**. VCF Operations installs the management pack, making it available for live monitoring.

### Designing a Management Pack using Prometheus

VCF Operations offers a wizard that makes it easy for you to design a management pack from Prometheus data.

Building a Prometheus-based management pack consists of the following steps. Once you start your design, you can save your work and pick up from where you left off. You can edit an existing design at any step.

- Define a Data Source: In this initial step, you define the Prometheus data source from which the management pack will collect information. You must specify the Prometheus instance that the management pack will integrate with, setting up the authentication, and ensuring that Prometheus is accessible for data retrieval. For more information, see Define a Source.
- Define Objects: In this step, you map metrics that are retrieved from Prometheus to meaningful objects and metrics within VCF Operations. For more information, see Add Objects.
- Specify Relationships: This step focuses on establishing relationships between the defined objects. By specifying how these objects interrelate, you can create a structured representation of the data, which aids in understanding dependencies and interactions within the monitored environment. For more information, see Define Object Relationships.
- Verify your Design: In this step, you validate the configurations that were made in the previous steps. It also involves testing the data collection and ensuring that objects and relationships are correctly defined. It’s a crucial step to ensure the management pack functions as intended before deployment. For more information, see Define Object Relationships.
- Install: As the final step, after you have reviewed and verified the design, you can install the management pack. For more information, see Install.

#### Define a Source

Start by identifying the Prometheus instance from which you intend to pull data. This step includes specifying the IP address or FQDN, API port, TLS configuration, and authentication settings.

**Data Source Connections**

- Collector: The collector node or cloud proxy from which the Management Pack Builder adapter instance will make requests to Prometheus during the design process.
- Prometheus Host: the IP address, hostname, or FQDN for the Prometheus instance that will be used during the design process.
- Port: The port hosting the Prometheus APIs. The default is 9090.
- TLS Configuration: Select from one of the following options:
  - Verify: Use TLS and verify the target's certificate
  - No Verify: Use TLS but do not verify the target's certificate
  - No TLS: Do not use TLS at all
- Authentication Type: Select from one of the following options:
  - Basic: Specify a username and password
  - No Authentication: No credentials are required

Once the form is complete, click **Test Connection**. The test connection confirms that the Prometheus instance is accessible with the provided configuration information and the API is returning the expected data.

The **Test Response** section shows you the list of jobs available on the Prometheus instance. In Prometheus, each type of monitored technology typically corresponds to one job. For example, all Clickhouse-related metrics are defined with the “clickhouse” job. By default, Prometheus defines its own self-monitoring metrics under the “prometheus” job.

The **Test Response** section also shows a **Log** tab, where you can review the test connection logs. If you are seeing a failed test connection, review the logs to determine the root cause of the failure.

Once you are done, click **Save Source**.

### Add Objects

Next, select Prometheus metrics that you want to convert into VCF Operations metrics and objects. Prometheus metrics have labels which can be used to uniquely identify objects. Prometheus metrics can be filtered and processed during their conversion to VCF Operations metrics.

**Add New Object Type**

1. Object Type:
   - Object Type: The type which will be assigned and visible in VCF Operations.
   - Prometheus Job: In Prometheus, each type of monitored technology typically corresponds to one job. Select which type of technology will be associated with this object type.
   - Object Icon: Select an icon to represent this object type. By default, all icons are shown. Select a category to filter the icons shown. After a management pack is installed, custom icons can optionally be uploaded in **Administration** > **Control Panel** > **Icons**.
2. Prometheus Data: Prometheus metrics related to the job selected previously are shown. Select the metrics that should comprise the new VCF Operations object type. Use the search bar to filter on metric name and label.

   **Note:**

   When defining object identifiers, you will only be able to select labels that are shared across all the selected metrics. All Prometheus metrics have the “instance” label by default.
3. Identifiers and Name: Select one or more labels to uniquely identify the objects in VCF Operations. You can optionally update the text that will be shown in the VCF Operations UI.

   After the identifying labels are defined, select one of them to be used as the object name.
4. Metrics Mapping: Each Prometheus metric selected previously is shown. A Prometheus metric can be mapped to one or more VCF Operations metrics on the new object type.
   - Metric Label: Optionally update the metric label to be shown in VCF Operations UI.
   - Function: The selection for function varies depending on the type of Prometheus metric:
     - Gauge metrics always use the **Current Total** function. This means the VCF Operations metric will report the sum of the latest values returned.
     - Counter and summary metrics can use a **Delta** or **Rate** function.

        - Delta: The VCF Operations metric will report the difference between the current value and previous value of the Prometheus metric.
        - Rate: The VCF Operations metric will report the difference between the current value and previous value of the Prometheus metric, divided by the time elapsed between collections.
    - Units: Specify the unit for this metric.
    - Filters: Optionally define one or more filters to include only a subset of the Prometheus metric's time series in the VCF Operations metric calculation. For example, you may want to split an HTTP Response metric into multiple VCF Operations metrics by filtering on response codes (2xx -> Successes, 4xx -> Failures, etc.).
        - =: Include time series where the specified label matches the provided text exactly.
        - !=: Include time series where the specified label does not match the provided text exactly.
        - =~: Include time series where the specified label matches the provided regex. Supports the same RE2 regex syntax that Prometheus supports.
        - !~: Include time series where the specified label does not match the provided regex. Supports the same RE2 regex syntax that Prometheus supports.
5. KPI: Indicates whether the data will be treated as a key performance indicator. KPIs are key metrics that are used in dashboards and resource detail pages. They should be metrics that are important to the status, performance, and health of the object.

**Extend Existing Object Type**

To extend an object type that is defined by another management pack already installed in VCF Operations with Prometheus data, select **Extend Existing**.

1. Object Type:
    - Select Existing Object Type: Select the type of object that will be extended with additional metrics. Use the search bar in the top-right to filter on **Object Type** and **Adapter**.
    - Prometheus Job: In Prometheus, each type of monitored technology typically corresponds to one job. Select which type of technology will be associated with this object type.
2. Prometheus Data: Prometheus metrics related to the job selected previously are shown. Select the metrics that should be added to the existing VCF Operations object type. Use the search bar to filter on metric name and label.

    **Note:**

    When defining object identifiers, you will only be able to select labels that are shared across all the selected metrics. All Prometheus metrics have the "instance" label by default.
3. Binding Labels: Select one or more binding labels from the selected Prometheus metrics to link to the existing objects in VCF Operations.
4. Object Binding: Use a combination of one or more binding labels and static text to define a matching pattern between the Prometheus metric labels and the existing object type's properties and identifiers. You may optionally apply a regex to any label, property, or identifier to modify the text that will be used for matching.
5. Metrics Mapping: Each Prometheus metric selected previously is shown. A Prometheus metric can be mapped to one or more VCF Operations metrics on the new object type.
    - Metric Label: Optionally update the metric label to be shown in VCF Operations UI.
    - Function: The selection for function varies depending on the type of Prometheus metric:
        - Gauge metrics always use the **Current Total** function. This means the VCF Operations metric will report the sum of the latest values returned.
        - Counter and summary metrics can use a **Delta** or **Rate** function.
            - Delta: The VCF Operations metric will report the difference between the current value and previous value of the Prometheus metric.
            - Rate: The VCF Operations metric will report the difference between the current value and previous value of the Prometheus metric, divided by the time elapsed between collections.
    - Units: Specify the unit for this metric.
    - Filters: Optionally define one or more filters to include only a subset of the Prometheus metric's time series in the VCF Operations metric calculation. For example, you may want to split an HTTP Response metric into multiple VCF Operations metrics by filtering on response codes (2xx -> Successes, 4xx -> Failures, etc.).
        - =: Include time series where the specified label matches the provided text exactly.

- `!=`: Include time series where the specified label does not match the provided text exactly.
- `=~`: Include time series where the specified label matches the provided regex. Supports the same RE2 regex syntax that Prometheus supports.
- `!~`: Include time series where the specified label does not match the provided regex. Supports the same RE2 regex syntax that Prometheus supports.

6. KPI: Indicates whether the data will be treated as a key performance indicator. KPIs are key metrics that are used in dashboards and resource detail pages. They should be metrics that are important to the status, performance, and health of the object.

#### What To Do Next

- Define Object Relationships: For more information, see Define Object Relationships.
- Verify your Design: For more information, see Verify your Design.
- Install: For more information, see Install.

## Importing or Exporting a Design

A JSON file is created when exporting a design. A JSON file can be imported into VCF Operations. The file is verified as a valid design file and the author and description is shown. Only valid designs can be exported.

#### Importing a Design

To import a design, click the **Import** button in the Management Pack Builder page. Browse to the location of the JSON file in your system. Only one design can be imported at a time.

VCF Operations verifies the validity and displays the name and description of the design. Ensure that another design of the same name does not exist. The design that you are importing must have a unique name.

After you import the design, it is displayed in the Management Pack Builder page. Verify the information in the **Design Status** column. You must provide the reference environment to test the design against. Click the imported design, and in the **Source** step of the wizard, specify the required fields.

#### Exporting a Design

Before you export a design, ensure that it does not contain private information, such as IP addresses, credentials, or IDs, outside of end-user configurable fields. Before sharing or storing your exported design in an unsecured location, review the export file to ensure it does not include any private information.

A zip file containing the JSON file is exported. You must extract the JSON file from the zip file before you can import it.

## Troubleshooting a Design

1. Request Log: Every time you make a test request or perform a test collection in Management Pack Builder, there are tabs which show the body, headers, and logs. In the case of an error response code, review the logs and headers for information regarding the cause of the error.
2. Third-party API documentation: ensure that the request you defined complies with the requirements described in the third-party API documentation.
3. Management Pack Builder Adapter logs: located under `$VCOPS_BASE/user/log/adapters/MPBAdapter` on the node or cloud proxy selected under **Source**. Review these logs for any additional errors or warnings.
4. If you suspect an error with the Management Pack Builder tool itself, you can open a support case, or review the server logs at `/usr/lib/vmware-vcops/user/log/integration-designer-controller.log`. You can also review the Suite API logs at `/usr/lib/vmware-vcops/user/log/suite-api for additional errors.`

   **Note:**

   VMware Support is limited to the functionality and performance of the Management Pack Builder application. Support does not include troubleshooting or designing customer-specific management packs or custom API

integrations. For questions about specific management pack designs, please post in the Management Pack Builder Community Page.

## Monitoring Multiple Cloud Accounts in VCF Operations

You can now monitor all your VMware cloud operations from the Overview page in VCF Operations. This overview page provides a comprehensive summary of your VMware cloud accounts which includes their geo-location, inventory, appliance health and management, and workload operations. You can also view the alerts and the cost for your entire VMware Cloud Infrastructure or individual VMware clouds.

### Where You Find the VCF Overview Tab

The overview page provides a consolidated view of all VMware cloud accounts on the **All VMware Clouds** page. The different tiles provide insights into the location, health, cost, and inventory of your cloud accounts. When you first login, only vCenter and VCF cards are visible.

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Home**. By default, the **VCF Overview** tab opens.

> **Note:**
>
> No data displays for cloud accounts that do not have a configured account. To view data for the other VMware clouds or public clouds, you must configure cloud accounts from the **Administration** > **Integrations** page. For more information, see The Accounts Tab.

### About the VCF Overview Tab

**Monitoring Accounts** tile: View the total number of configured accounts under each account type (VCF, vCenter, Domains) that are collecting data.

**Inventory** tile: View the summarized resources count of the collecting accounts, for example, Datacenter, Cluster, Host, VM, Datastore, vSphere Distributed Switch, vSphere Distributed Port Group) for the whole cloud infrastructure.

**Findings** tile: View the diagnostic findings of your VMware Clouds to track the health of your cloud accounts and manage their health.

**Certificates** tile: Certificates information is available only for VCF license entitled vCenter instances. For more information, see Licensing Overview.

**Overall Capacity| Capacity Remaining| Time Remaining**: View the overall capacity, capacity remaining, and the time remaining before the capacity runs out. If no data displays as part of the capacity and time remaining sections, check your account configuration, and make sure they are collecting data.

**Cost**: View the total cost of ownership, potential savings, and realized savings. The amount is calculated from the first of the month to the current date. This value resets at the beginning of every month.

**Alerts** tile: View the total number of alerts need attention. Alerts of all cloud accounts are consolidated and represented graphically dating back a week from the current date dynamically.

**Green Score** tile: View the status of your VMware Cloud that includes its green score, power consumption, carbon footprint, and overall environmental impact. To view the Green Score information in more detail, click **View Green Score**. For more information, see Configuring Green Score.

**Compliance** tile: View the compliance scores and misconfigurations of your cloud accounts.

### VMware Cloud - Example: vCenter Account

The values displayed in the individual VMware cloud accounts like vCenter are based on their total number of accounts.

> **Note:**
>
> To view the geographical location of the accounts configured for vCenter and VCF, you must assign them to a physical data center. For more information, see Adding Physical Data Centers in VCF Operations.

**Monitoring Accounts** tile: View the total number of vCenter instances that are collecting data.

**Inventory** tile: View the object types of the data collecting vCenter instances, for example, Datacenter, Cluster, Host, VM, Datastore, vSphere Distributed Switch, vSphere Distributed Port Group. Unspecified object types are not reflected in the tile.

**Top Objects Growth Trend** tile: Displays the growth trend of the top objects dating back a month from the current date dynamically.

# VCF Account in VCF Operations

In VCF a VCF domain is a policy-based resource construct with specific availability and performance attributes. It combines compute (vSphere), storage (vSAN), networking (NSX), and VCF Operations fleet management to form a single consumable entity that creates logical resource pools across compute, storage, and networking.

There are two types of VCF domains - the management domain and the workload domain. For more information, see Overview.

Configure the VCF account in VCF Operations to monitor these constructs of VCF.

## Configuring a Standalone VCF Account in VCF Operations

You must configure a VCF account to monitor a VCF Instance.

- Configure a physical data center in VCF Operations. For more information, see Adding Physical Data Centers in VCF Operations

After configuration, all VCF domains within the instance are automatically discovered and configured along with their connection details and credentials of underlying adapters for vCenter, vSAN, and NSX.

> **Note:**
>
> All instances in the VCF Fleet are automatically added to VCF Operations and do not require manual creation of VCF accounts.

1. From the left menu, click **Administration** > **Integrations**.
2. On the **Accounts** tab, click **Add**.
3. On the **Accounts Types** page, click **VMware Cloud Foundation**.
4. Enter a Name and Description for the account.
5. Optional: Select the **Physical Data Center** you want to associate with the VCF account.
6. Enter the FQDN for the **SDDC Manager** you are trying to connect.
7. To add credentials for the VCF Instance, click the **Add** icon, and enter the required credentials.

   The credentials must be associated with the admin role in VCF.

   > **Note:**
   > If you are using an AD or domain integrated account for authenticating your VCF Instance, ensure you enter the username as username@domain or domain\username.
8. Determine which VCF Operations cloud proxy/ group is used to manage the account. From the **Cloud Proxy/ Group** drop-down, select the cloud proxy that you deployed as the collector for this VCF account.

   If you have multiple cloud proxies/ groups in your environment, you can distribute the workload to optimize performance. Select the cloud proxy/ group to manage the adapter processes for this instance. The **SDDC Manager** FQDN must be reachable from selected cloud proxy/ group.
9. Click **Validate Connection** to validate the connection.

   The Review and Accept Certificate wizard appears. Click **Accept** to continue the validation.

10. Optional: In the **Log Operations** section, activate or deactivate the collection of SDDC Manager logs. After you enable this setting, you can use the Log Management features and capabilities to analyze SDDC Manager logs.

    **Note:**

    This is supported for SDDC Manager 9.1.1 and higher only.

    a) This setting is activated by default. Activating this setting overrides any log configuration that is done on the SDDC Manager.
    b) By default, logs are collected directly into the Logs cluster. To collect logs into a unified cloud proxy instead, you must set one up. Note that the default unified cloud proxy cannot be used for this collection type. An advanced unified cloud proxy must be configured instead.
    c) To add filters and other settings, see Managing Collection from Log Sources.

11. Optional: Click **Advanced Settings**.

    - **Enable Domain Monitoring on Creation**: Change this setting to **true** to enable data collection and monitoring of newly discovered and configured domains.

      **Note:**

      By default, this setting is set to **false**. If you configure a VCF account with the default setting, data collection and monitoring of domains is disabled. If you edit the VCF account and change this setting to **true**, data collection and monitoring is enabled but it is done only for the newly discovered domains.
    - **VCF Configuration Limit File Name**: Enter the name of the file that contains the VCF configuration max soft and hard limits and their configured values in VCF Operations.

12. Click **Add** and select an add option for this VCF instance.

    **Note:**

    License and vSphere Client plug-in management is supported only for VCF accounts of versions 9.0 or later. If your VCF account is 9.0 or later and is not managed by any VCF Operations instance, the current VCF Operations instance takes up the license and vSphere Client plug-in management. If you do not have the required privileges for license and vSphere Client plug-in management, VCF account will be added only for monitoring purposes. For more information, see Use and Configure Your vSphere Client.

    After you integrate a VCF account with a VCF Operations instance for license management, it takes up to 15 minutes before the VCF account appears in the **License** tab of VCF Operations.

    If your VCF account is a version before 9.0, you can only activate vSphere Client plug-in management. If your VCF account is a version before 9.0, and is not managed by any VCF Operations instance, the current VCF Operations instance takes up the vSphere Client plug-in management. If you do not have the required privileges for vSphere Client plug-in management, VCF account will be added only for monitoring purposes.

    - **Add all associated vCenter systems only for monitoring and fleet management**: Use this option if you want multiple VCF Operations instances to monitor and provide fleet management to vCenter systems of the VCF account you are adding.
    - **Add all associated vCenter systems for monitoring, fleet management, and license and vSphere Client plug-in management by replacing the current integration**: Use this option to replace existing VCF Operations integration with a newer integration. For versions 9.0 or later, you can use this option if another VCF Operations provides license and vSphere Client plug-in management for vCenter you are adding and you want to replace it with the current VCF Operations. After you remove the current integration, you must assign new licenses for this vCenter. For more information, see Assign a Primary License to a vCenter Instance.

      For versions before 9.0, license management is not applicable. You can use this option if another VCF Operations provides vSphere Client plug-in management for the management domain vCenter for the VCF account you are adding. All current integrations of all associated vCenter systems get replaced.

      **Note:**

      If the management domain vCenter does not have a license and vSphere Client plug-in management, the current VCF Operations starts to manage it automatically.

For VCF 9.0 and later, the management domain vCenter, vSAN, and NSX are created using system-managed credentials. Workload domains are configured after one collection cycle.

If Log Collection and Network and Flow Collection are activated for vCenter and NSX, separate system-managed credentials are created for both.

The VCF account, with the configured domains, is added to the **Accounts** page. The newly added VCF account does not start monitoring the data automatically and you must manually initiate the data collection.

13. On the **Accounts** tab, locate the VCF account, click the vertical ellipsis, and then click **Start Collecting All**.
14. Optional: You can use your VCF account to monitor and manage license and vSphere client plug-in.
    - To bulk activate license and vSphere Client plug-in management for all your VCF accounts of versions 9.0 or later, select the VCF account, and click **Activate Management**.
    - To activate license and vSphere Client plug-in management for a particular VCF account, select the VCF account, click the vertical ellipsis, click **Edit**, and then click **Manage Integrations**. You must have the required privileges to manage integration.

The VCF account is added and starts collecting data in VCF Operations.

You can view the operations of your VCF accounts and their domains from the VCF Health page. For more information, see What is VCF Health in Diagnostics.

If you are using **SDDC Manager** 9.0 or later, you can also monitor your VCF account and collect data seamlessly using system-managed credentials. After you create a VCF account in VCF Operations, you can edit the VCF account and activate **System Managed Credentials.** Activating system-managed credentials for your VCF account does not affect the underlying vCenter and NSX accounts. Newly created vCenter and NSX accounts are automatically configured using system-managed credentials if the corresponding vCenter and NSX endpoints are 9.0. For password rotation, click **Rotate** to rotate your system-managed credential password. You must rotate system-managed credentials for individual endpoints. For more information, see Account Management Design.

Optionally, you can also configure the vCenter, vSAN, NSX, and Service Discovery instances in the VCF account.

- To configure a vCenter account, see Configuring a vCenter Account in VCF Operations.
- To configure a vSAN account, see Configuring a vSAN Account.
- To configure the NSX account, see Configuring the NSX Account in VCF Operations.
- To configure Service Discovery, see Configure Service and Application Discovery.

# vCenter Account in VCF Operations

The vCenter account connects VCF Operations to vCenter instances. You collect data and metrics from those vCenter instances, monitor them, and run actions on them.

VCF Operations evaluates the data in your environment, identifying trends in object behavior, predicting possible problems and future capacity for objects in your system based on those trends, and alerting you when an object exhibits defined symptoms.

## Configuring the vCenter Account

You can configure a vCenter account in VCF Operations to connect your VCF Operations environment to your vCenter instances.

## How Adapter Credentials Work

The vCenter credentials that you use to connect VCF Operations to a vCenter instance, determines what objects VCF Operations monitors. Ensure that you configure adapters and users correctly, and to avoid some of the following issues.

- If you configure the adapter to connect to a vCenter instance with credentials that have permission to access only one of your three ESX hosts, every user who logs in to VCF Operations sees only the one ESX host, even when an individual user has privileges on all three of the ESX hosts in the vCenter.

- If the provided credentials have limited access to objects in the vCenter, even VCF Operations administrative users can run actions only on the objects for which the vCenter credentials have permissions.
- If the provided credentials have access to all the objects in the vCenter, any VCF Operations user who runs actions is using the VCF Operations credentials.

**Controlling User Access to Actions**

Use the vCenter adapter to run actions on vCenter from VCF Operations. If you choose to run actions, you must control user access to the objects in your vCenter environment. You control user access for local users based on how you configure user privileges in VCF Operations. If users log in using their vCenter account, then the way their account is configured in vCenter determines their privileges.

For example, you might have a vCenter user with a read-only role in vCenter. If you give this user the VCF Operations*Power User* role in vCenter rather than a more restrictive role, the user can run actions on objects because the adapter is configured with credentials that has privileges to change objects. To avoid this type of unexpected result, configure local VCF Operations users and vCenter users with the privileges you want them to have in your environment.

To configure a vCenter account, see Configuring a vCenter Account in VCF Operations.

## Configuring a vCenter Account in VCF Operations

To manage your vCenter instances in VCF Operations, you must configure an account for each vCenter instance. The account requires the credentials that are used for communication with the target vCenter.

- Verify that you know the vCenter credentials that have sufficient privileges to connect and collect data, see Privileges Required for Configuring a vCenter Account. If the provided credentials have limited access to objects in vCenter, all users, regardless of their vCenter privileges see only the objects that the provided credentials can access. At a minimum, the user account must have Read privileges and the Read privileges must be assigned at the datacenter or vCenter level.
- You must install the Log management appliance for VCF to enable log collection and analysis in VCF Operations. See *Deploy, Converge, Upgrade* for more information on deployment and upgrade. For more information on log analysis in VCF Operations, see Configuring and Analyzing Logs.

  **Note:**

  Any account credentials that you add are shared with other account administrators and VCF Operations collector hosts. Other administrators might use these credentials to configure a new account or to move an account to a new host.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**.
2. On the **Accounts** tab, click **Add**.
3. On the Accounts Type page, click **vCenter**.
4. Enter a display name and description for the account.

   **Note:**

   Enter the name for the vCenter instance as you want it to appear in VCF Operations. A common practice is to include the IP address so that you can readily identify and differentiate between instances.
5. Optional: Select the **Physical Data Center** you want to associate with the vCenter account.

   If no physical data center is created or if you want to create a new physical data center for your account, you can add a new physical data center. For more information, see Adding Physical Data Centers in VCF Operations.
6. In the vCenter text box, enter the FQDN or IP address of the vCenter instance to which you are connecting.

   **Note:**

   While configuring VCF Single Sign-On, enter the of the FQDN of the vCenter instance to which you are connecting. vCenter instances configured using IP address are not included in VCF accounts. If you want the vCenter instance to be part of the VCF account, enter the FQDN.

7. To add credentials for the vCenter instance, click the **Add** icon, and enter the required credentials.

   The vCenter credential must have `Performance > Modify intervals` permission activated in the target vCenter to collect VM guest metrics. Optionally, you can use alternate user credentials for actions. Enter an **Action User Name** and **Actions Password**. If you do not enter an **Action User Name** and **Actions Password**, the default user specified is considered for actions.

   **Note:**

   Credentials are stored in VCF Operations and can be used for one or more instances of the vCenter.

   **Note:**

   To monitor application services and operating systems, it is recommended that you enter action credentials with guest operations privileges. For more information, see Privileges Required for Configuring a vCenter Account.

8. Determine which VCF Operations cloud proxy/ group is used to manage the account. From the **Cloud Proxy/ Group** drop-down, select the cloud proxy you deployed as the collector for this vCenter account.

   **Note:**

   The vCenter FQDN or IP address must be reachable from the selected cloud proxy/ group. If you have multiple cloud proxies/ groups in your environment, you can distribute the workload to optimize performance. Select the cloud proxy/ group to manage the adapter processes for this instance.

9. Click **Validate Connection** to validate the connection with your vCenter instance.

10. In the **Review and Accept Certificate** dialog box, review the certificate information.

    - If the certificate presented in the dialog box matches the certificate for your target vCenter instance, click **OK**.
    - If you do not recognize the certificate as valid, click **Cancel**. The validation test fails and the connection to vCenter instance is incomplete. To complete the adapter configuration, you must provide a valid vCenter URL and verify that the certificate on the vCenter is valid.

11. The account is configured to run actions on objects in vCenter from VCF Operations. If you do not want to run actions, deselect **Activate** for Operational Actions.

12. Optional: To collect logs, click **Activate Log Collection**. For more information, see Configuring and Analyzing Logs.

    a) This setting is activated by default.

    a) By default, logs are collected directly into the Logs cluster. To collect logs into a unified cloud proxy instead, you must set one up. Note that the default unified cloud proxy cannot be used for this collection type. An advanced unified cloud proxy must be configured instead.

    **Note:**

    When you export vCenter information from one VCF Operations instance and import it to another, the log collection information is not transferred.

13. Optional: To collect network and flow, click **Activate Network and Flow**. For more information, see Add VMware vCenter.

14. To modify the advanced options regarding collectors, object discovery, or change events, expand the **Advanced Settings**.

    For information about these advanced settings, see Configuring Advanced Settings for a vCenter Account.

15. Click **Add** to select an additional option for this vCenter instance.

    **Note:**

    License and vSphere Client plug-in management is supported only for vCenter accounts of version 9.0 or later. If your vCenter is 9.0 or later and is not managed by any VCF Operations instance, the current VCF Operations instance takes up the license and vSphere Client plug-in management. If you do not have the required privileges for license and vSphere Client plug-in management, the vCenter account will be added only for monitoring purposes. For more information, see Use and Configure Your vSphere Client.

After you integrate a vCenter account with a VCF Operations instance for license management, it takes up to 15 minutes before the vCenter account appears in the **License** tab of VCF Operations.

If you have an earlier version of vCenter accounts, you can only activate vSphere Client plug-in management. If your vCenter is pre 9.0, and is not managed by any VCF Operations instance, the current VCF Operations instance takes up the vSphere Client plug-in management. If you do not have the required privileges for vSphere Client plug-in management, vCenter account will be added only for monitoring purposes.

- **Add vCenter only for monitoring**: Use this option if you want to proceed with the existing VCF Operations integration and use the new vCenter account for monitoring purposes only.
- **Add vCenter for monitoring and license and vSphere Client plug-in management by replacing the current integration**: Use this option to replace existing VCF Operations integration with a newer integration.

  For versions 9.0 or later, you can use this option if another VCF Operations provides license and vSphere Client plug-in management for vCenter you are adding and you want to replace it with the current VCF Operations. After you remove the current integration, you must assign new license to this vCenter instance. For more information, see Assign a Primary License to a vCenter Instance.

  For versions prior to 9.0, license management is not applicable. You can use this option if another VCF Operations provides vSphere Client plug-in management for vCenter you are adding and you want to replace it with the current VCF Operations.

Newly created vCenter accounts do not start monitoring the data automatically and you must manually initiate the data collection.

16. On the Accounts tab, locate the vCenter account, click the vertical ellipsis, and then click **Start Collecting**.
17. Optional: You can use your vCenter account to monitor and manage license and vSphere client plug-in.
    - To bulk activate license and vSphere Client plug-in management for all your vCenter accounts of versions 9.0 or later, select the vCenter account, and click **Activate Management**.
    - To activate license and vSphere Client plug-in management for a particular vCenter account, select the vCenter account, click the vertical ellipsis, click **Edit**, and then click **Manage Integrations**. You must have the required privileges to manage integration. For more information, see Privileges Required for Configuring a vCenter Account.

The vCenter account is added to the list and VCF Operations begins collecting metrics, properties, and events from the vCenter instance. Depending on the number of managed objects, the initial collection can take more than one collection cycle. A standard collection cycle begins every 5 minutes.

For information about the network port that VCF Operations uses to communicate with a vCenter instance and VCF Operations components, see VMware Ports and Protocols.

You can activate vSAN configuration for your account. For more information, see Configuring a vSAN Account.

You can use the vCenter for service discovery, see Configure Service and Application Discovery.

### Privileges Required for Configuring a vCenter Account

To configure your vCenter adapter instance in VCF Operations, you need sufficient privileges to monitor and collect data and to perform vCenter actions. You can configure these permissions as a single role in vCenter to be used by a single service account or configure them as two independent roles for two separate service accounts.

The vCenter account requires credentials with the following privileges configured in vCenter to be able to monitor and collect data and perform necessary actions in the vCenter instance.

**Note:**

The vCenter role is created with a **Read Only** role with three system-defined privileges: **System.Anonymous**, **System.View**, and **System.Read**. For more information, see Using vCenter Roles to Assign Privileges.

**Table 1183: Privileges for Configuring a vCenter Adapter: Monitoring and Data Collection**

| Task | Privilege |
|---|---|
| Property Collection | **System > Anonymous**: This privilege is added automatically when you create a user account and it is not visible in vSphere.<br>**System> View** |
| Performance Metrics Collection | **Performance > Modify intervals**<br>**System > Read**: This privilege is added automatically when you create a user account and it is not visible in vSphere. |

When you add a custom role and do not assign any privileges to it, the role is created as a Read Only role with three system-defined privileges:<br>• **System > Anonymous**<br>• **System > View**<br>• **System > Read**<br>**Note:**<br>You must configure the permission on the top-level folder within the vCenter Server inventory, and verify that the **Propagate to children** check box is selected. |
| Syslog configuration on ESX hosts | • **Host > Configuration> Change settings**<br>• **Host > Configuration> Network configuration**<br>• **Host > Configuration> Advanced Settings**<br>• **Host > Configuration> Security profile and firewall**<br>• **Certificates > Manage certificates** - required only if ESXi syslog collection is configured via SSL (Secure collection)<br>**Note:**<br>You must configure the permission on the top-level folder within the vCenter Server inventory, and verify that the **Propagate to children** check box is selected. |

**Table 1185: Privileges for collecting compliance-related properties**

| Task | Privilege/Role |
|---|---|
| Collecting the following properties on the vCenter adapter instance object:<br>• Appliance\|Maximum Number of Failed Login Attempts<br>• Appliance\|Unlock time<br>• Appliance\|Time Interval Between Failures<br>• Appliance\|Is Root Account Enabled<br>• Appliance\|Root Account Expiration Date<br>• Appliance\|Console Cli Enabled<br>• Appliance\|Has Recovery Backup Jobs<br>• Appliance\|Has Networking Firewall Inbound Rules<br>• Appliance\|Has Logging Forwarding Configs<br>• Appliance\|Time Sync Mode | **Administrator** |

For more information about tasks and privileges, see Defined Privileges.

## Configure User Access for Actions

To ensure that users can run actions in VCF Operations, you must configure user access to the actions.

You can create multiple roles, each granting access to specific actions. Administrators and super users already have full permissions. To simplify management, assign roles to user groups instead of configuring individual users.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Control Panel**, and then click the **Access Control** tile.
   a) Click the **Roles** tab.
   b) Click the **Add** icon, and enter a name and description for the role.
   c) To **Assign Permissions**, select the permissions. You can select a whole permission group or individual permissions within a group.
   d) Select one or more permissions, and then click **SAVE**.
2. To create a user group, return to the **Access Control** page.
   a) Click the **User Groups** tab, and click the **Add** icon.
   b) Enter a name and description for the group.
   c) To **Assign Roles and Scopes**, select a role for the user group and assign a scope for each role. You can add one or more roles and assign scope for each role.
   d) To **Assign Users**, select the users you want to assign to the user group.
   e) Click **SAVE**.

Test the users that you assigned to the group. Log out, and log back in as one of the users. Verify that this user can run the expected actions on the selected adapter.

## Configuring Advanced Settings for a vCenter Account

To begin monitoring your environment with VCF Operations, you configure the vCenter account. The solution includes the vCenter account that collects data from the target vCenter instances. For more information, see Configuring a vCenter Account in VCF Operations.

### Where You Find the Solution- vCenter

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. On the **Accounts** tab, click **ADD**, and then select **vCenter**.

## Advanced Settings Options for Configuring a vCenter Account

Configure and modify the vCenter account on the Account Information page.

| Option | Description |
|---|---|
| Advanced Settings | Provides options related to designating specific collectors to manage this account, managing object discovery and change events. |
| Auto Discovery | Determines whether new objects added to the monitored system are discovered and added to VCF Operations after the initial configuration of the account.<br>• If the value is true, VCF Operations collects the information about any new objects that are added to the monitored system after the initial configuration. For example, if you add more ESX hosts and virtual machines, these objects are added during the next collections cycle. This is the default value.<br>• If the value is false, VCF Operations monitors only those objects that are present on the target system when you configure the account. |
| Process Change Events | Determines whether the account uses an event collector to collect and process the events generated in the vCenter instance.<br>• If the value is true, the event collector collects and publishes events from vCenter. This is the default value.<br>• If the value is false, the event collector does not collect and publish events. |
| Process VC Tasks | Determines whether the account uses a task collector to collect and process tasks that are created in the vCenter instance.<br>• If the value is true, the task collector collects and publishes tasks from vCenter instance. This is the default value.<br>• If the value is false, the event collector does not collect and publish tasks. |
| Activate Collecting vSphere Distributed Switch<br>Activate Collecting Virtual Machine Folder<br>Activate Collecting vSphere Distributed Port Group | When set to false, reduces the collected data set by omitting collection of the associated category. |
| Maximum Number Of Virtual Machines Collected | Reduces the collected data set by limiting the number of virtual machine collections.<br>To omit data on virtual machines and have VCF Operations collect only host data, set the value to zero. |
| Provide data to vSphere Predictive DRS | vSphere Predictive DRS proactively load balances vCenter cluster to accommodate predictable patterns in the cluster workload.<br>VCF Operations monitors virtual machines running in vCenter, analyzes longer-term historical data, and provides forecast data about predictable patterns of resource usage to Predictive DRS. Based on these predictable patterns, Predictive DRS moves to balance resource usage among virtual machines.<br>Predictive DRS must also be activated for the vSphere Clusters managed by vCenter instances monitored by VCF Operations. Refer to the vSphere Resource Management for details on activating Predictive DRS on a per vSphere cluster basis.<br>When set to true, designates VCF Operations as a predictive data provider, and sends predicative data to vCenter . You can only register a single active Predictive DRS data provider with vCenter at a time. |
| Activate Actions | Activating this option helps in triggering the actions that are related to vCenter. |
| Cloud Type | Identifies the type of vCenter that is used in VCF Operations. |
| **vCenter** ID | A globally unique identifier associated with the vCenter instance. |
| Deactivate collecting Guest File Systems with names containing | Provide a comma-separated list of strings. If these strings are found in any guest files system mount point name, that guest file system will not be collected. |
| Enable vSphere Supervisor Collection | Enables the collection of the auto discovered vSphere Supervisor cluster. |

| Option | Description |
|---|---|
| Activate vCenter -initiated metric collection | If the value is true, it enables the collection of Host and VM level GPU metrics.<br>Change the value to false to stop metric collection. It may take up to 10 minutes to completely disable metric collection. |
| vCenter- initiated metric collection sample interval | The sample interval in seconds between vCenter initiated metric collection. To change the sample interval, you must first disable vCenter initiated metric collection. Update the collection sample interval before restarting the metric collection. |

You can find the vSphere Hardening Guides at VMware Security Hardening Guides.

Click **Save** to finish configuration of the solution.

# vSAN Account in VCF Operations

You can make vSAN operational in a production environment by using dashboards to evaluate, manage, and optimize the performance of vSAN objects and vSAN-activated objects in your vCenter system.

vSAN extends the following features:

- Discovers vSAN disk groups in a vSAN datastore.
- Identifies the vSAN-activated cluster compute resource, host system, and datastore objects in a vCenter system.
- Automatically adds related vCenter components that are in the monitoring state.
- Support for vSAN datastores in workload optimization with cross-cluster rebalance actions.
  - You can move VMs from one vSAN datastore to another vSAN datastore.
  - You can optimize the container if all the vSAN clusters are not in resync state.
  - VMs with different storage policies for each disk or VMs with different types of storage for each disk will not be moved.
  - You can generate a re-balance plan only if sufficient disk space is available at the destination vSAN datastore (The vSAN datastore slack space is also considered).
  - The storage policy assigned to the VM is considered during the workload optimization (Compatibility check is performed against the storage policy).
  - VM migration from vSAN datastore to vSAN stretched clusters is not supported.

## Configuring a vSAN Account

You can manage and monitor the health and performance of your vSAN clusters and remediate alerts in VCF Operations.

- You must have a vCenter Adapter instance configured and monitoring the same vCenter instance that is used to monitor the vSAN and Storage Devices.

  **Note:**

  Only vCenter systems that are configured for both vCenter adapter and vSAN adapter appear in the inventory tree under the vSAN and storage devices. Verify that vCenter that you use to configure the vSAN adapter instance is also configured as a vCenter adapter instance for the VMware vSphere solution. If not, add a vCenter adapter instance for that vCenter. For more information, see Configuring a vCenter Account in VCF Operations.

- You must open port 5989 between the host and any VCF Operations node on which the vSAN adapter resides. This is applicable when the vSAN version in vSphere is 6.6 or lower.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**.
2. On the **Accounts** tab, select the vCenter instance.

   You must configure the vCenter instance before you configure vSAN on it. To configure the vCenter instance, see Configuring a vCenter Account in VCF Operations.

3. Click the vSAN tab and click the **vSAN configuration** toggle switch to activate vSAN.

   **Note:**

   Once the vSAN adapter instance is activated and saved, the activated vSAN configuration option is not visible.

4. The credentials provided for the vCenter instance are also used for vSAN adapter instance. If you do not want to use these credentials, you can click **Use alternate credentials** option.
   a) Click the plus sign next to the Credential field and enter the details in the **Manage Credentials** dialog box.
   b) Enter the credential name, vCenter user name, and password and click **OK**.
5. Choose **Enable SMART data collection**, to activate SMART data collection for physical disk devices.
6. Click **Validate Connection** to validate the connection with your vCenter instance.
7. Accept the vCenter security certificate.
8. Click **Add** to save the configurations.

   Newly created vCenter account with vSAN activated do not start monitoring the data automatically and you must manually initiate the data collection.
9. On the Accounts tab, locate the vCenter account, click the vertical ellipsis and then click **Start Collecting All**.

The vSAN account starts collecting data. The newly connected vSAN account information will appear on all vSAN dashboards after five minutes. You can get an overview of the vSAN health and performance in the Storage Operations page. For more information, see Monitoring Storage Operations. To view vSAN performance for each cluster individually and to drill down info-specific performance criteria, use the vSAN Performance dashboard.

To verify that the adapter is configured and collecting data from vSAN objects, wait a few collection cycles, then view application-related data.

- Inventory. Verify that all the objects related to the vSAN instance are listed. Objects should be in the collecting state and receiving data.
- Dashboards. Verify that vSAN Capacity Overview, Migrate to vSAN, vSAN Operations Overview, and Troubleshoot vSAN, are added to the default dashboards.
- Under **Inventory** > **vSAN and Storage Devices**, verify that the vSAN hierarchy includes the following related vCenter system objects:
  – vSAN World
  – Cache Disk
  – Capacity Disk
  – vSAN-activated vCenter clusters
  – vSAN Fault Domains (optional)
  – vSAN-activated Hosts
  – vSAN Data stores
  – vSAN Disk Groups
  – vSAN Data store related VMs
  – vSAN Witness Hosts (optional)

## Verify that the Adapter Instance is Connected and Collecting Data

You configured an adapter instance of vSAN with credentials for a vCenter. Now you want to verify that your adapter instance can retrieve information from vSAN objects in your environment.

**Table 1186: Object Types that vSAN Discovers**

| Object Type | Description |
|---|---|
| vSAN Adapter Instance | The vSAN instance. |
| vSAN Cluster | vSAN clusters in your data center. |

| Object Type | Description |
|---|---|
| vSAN Datastore | vSAN datastores in your data center. |
| vSAN Disk Group | A collection of SSDs and magnetic disks used by vSAN. |
| vSAN Fault Domain | A tag for a fault domain in your data center. |
| vSAN Host | vSAN hosts in your data center. |
| vSAN Witness Host | A tag for a witness host of a stretched cluster, if the stretched cluster feature is activated on the vSAN cluster. |
| vSAN World | A vSAN World is a group parent resource for all vSAN adapter instances. vSAN World displays aggregated data of all adapter instances and a single root object of the entire vSAN hierarchy. |
| Cache Disk | A local physical device on a host used for storing VM files in vSAN. |
| Capacity Disk | A local physical device on a host used for read or write caching in vSAN |

The vSAN adapter also monitors the following objects discovered by the VMware vSphere adapter.

- Cluster Compute Resources
- Host System
- Datastore

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** > **Adapter Instances**, and then click **vSAN Adapter Instance**.
2. Select the adapter instance name to display the list of objects discovered by your adapter instance.
3. Slide the display bar to the right to view the object status.

| Object Status | Description |
|---|---|
| Collection State | If green, the object is connected. |
| Collection Status | If green, the adapter is retrieving data from the object. |

4. Deselect the adapter instance name and expand the **Object Types** tag.
   Each Object Type name appears with the number of objects of that type in your environment.

If objects are missing or not transmitting data, check to confirm that the object is connected. Then check for related alerts.

To ensure that the vSAN adapter can collect all performance data, the vSAN performance service must be activated in vSphere. For instructions on how to activate the service, see Turn on vSAN Performance Service in KB 326483.

To collect capacity metrics for Cache Disks, ensure that the Performance Service is enabled for the vSAN cluster. For more information, see Broadcom knowledge base article 405036.

If the vSAN performance service is deactivated or experiencing issues, an alert is triggered for the vSAN adapter instance and the following errors appear in the adapter logs.

```
ERROR com.vmware.adapter3.vsan.metricloader.VsanDiskgroupMetricLoader.collectMetrics
   - Failed to collect performance metrics for Disk Group
com.vmware.adapter3.vsan.metricloader.VsanDiskgroupMetricLoader.collectMetrics
   - vSAN Performance Service might be turned OFF.
com.vmware.adapter3.vsan.metricloader.VsanDiskgroupMetricLoader.collectMetrics
   - (vim.fault.NotFound)
   {
   faultCause = null,
   faultMessage = (vmodl.LocalizableMessage)
      [
         com.vmware.vim.binding.impl.vmodl.LocalizableMessageImpl@98e1294
      ]
   }
```

## vSAN Log Analytics Enhancements

When VCF Operations is integrated with Log management, you can view and troubleshoot Log management object issues within VCF Operations. Earlier you could troubleshoot issues related only to vCenter objects, but now you can troubleshoot issues related to vSAN also.

The enhancements to vSAN log analytics include use of specific queries to retrieve log information for the following vSAN objects:

- vSAN Cluster
- Witness Host
- Disk Group
- Cache Disk
- Capacity Disk

### Where You Find vSAN Object Logs

Navigate to the vSAN Object Details page, and click the **Logs** tab.

> **Note:**
>
> If you are not logged in to Log management, then VCF Operations prompts you to log in to Log management with your login credentials.

VCF Operations uses special queries for each object type. Using the special queries for vSAN objects, you can perform the following actions:

- View interactive analytics for the selected vSAN object.
- Retrieve log details for the vSAN object.
- Analyze and troubleshoot issues related to the vSAN object.

## Monitoring Storage Operations

The Storage Operations page is a centralized storage dashboard for vSAN and non-vSAN storage types in VCF Operations.

To get an overview of your datastore inventory, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Overview** > **Storage**.

Use the storage operations page to view storage-related alerts and view the usage and distribution of your vSAN and non-vSAN datastores. You can filter vSAN and non-vSAN datastores for a more detailed overview.

> **Note:**
>
> To view vSAN related data on the storage operations page, you must configure a vSAN enabled vCenter account and ensure that the vCenter instance is collecting data in VCF Operations. For more information, see Configuring a vCenter Account in VCF Operations.

You can view the vSAN Cluster Health Score and the different types of vSAN clusters available in VCF Operations. Additionally you can hover on any cluster pin to view the basic performance metrics like IOPS, Latency, and Throughput for that particular vSAN cluster. The storage operations page also displays the **vSAN Clusters** table that displays the vSAN cluster information.

### vSAN Cluster Performance Widget

The vSAN cluster performance widget provides an overview of the performance of the vSAN clusters in relation to one another. To view performance diagnostics of all the vSAN clusters, click **View Diagnostics**. The **Performance Insights** tab opens and displays two types of performance insights:

- **Proactive insights**: Proactive insights report any actively ongoing critical vSAN cluster issues that impact VM latency and require immediate resolution. To activate proactive insights for your clusters, ensure that VCF Operations for Real Time Data Service is activated. For more information, see Deploying VCF Operations for Real Time Data Service.

You can deactivate proative insights or conditionally deactivate proactive insights for some clusters. For more information, see KB article 420866.

- **On demand insights**: On demand insights only appears after you manually run diagnostics for a target vSAN cluster. To run on demand diagnostics, click **Run New Diagnostics**, select a **Diagnostic goal**, select the target vSAN cluster, and then set the desired time range.
  - **Troubleshooting**: Run performance diagnostics for a cluster already in use with a running workload. This helps identify and troubleshoot performance issues impacting the workload.
  - **Benchmarking and Optimizing**: Run performance diagnostics for a new cluster before adding any workload. This enables diagnostics with a **Benchmark goal**.

To view detailed information about a performance insight, click the expand icon. The details pane shows the cluster information, diagnostic results, and suggested remediation steps.

After resolving an issue reported by a proactive insight, it is removed from the **Performance Insights** table when the next proactive insight runs. If you resolve an issue reported by on demand diagnostics, you must run new diagnostics to confirm that the issue is resolved.

**Note:**

If you run on-demand diagnostics on a HCIBench and the recommendation is to tune IO parameters to get closer to the goal, re-run HCIBench run with the recommended IO parameters. Once done, you can re-run on-demand diagnostics on the new HCIBench to confirm that the issue is resolved.

# NSX Account in VCF Operations

The NSX adapter allows you to retrieve alerts and findings from NSX to VCF Operations.

The NSX adapter supports adapter configuration using VIDM for NSX versions 3.0 and above. The roles and permissions associated with the VIDM users collecting the NSX adapter data are:

| Roles | Permissions |
|---|---|
| Enterprise Admin | Collect all data. |
| Network engineer | • Collect all the NSX resources except the Load Balancer and collect limited routers data.<br>Router data collected:<br>– Tier 0 router connected to logical switch.<br>– Tier 1 router created from vCloud Director. |
| • Security Engineer<br>• Security Operator<br>• Auditor | Collect all data except the load balancer. |
| • LB Admin<br>• LB Auditor<br>• Netxpartner Admin | Cannot collect any data. |

## Configuring the NSX Account in VCF Operations

You can configure your NSX account in VCF Operations.

To view the roles and permissions that are associated with the VIDM users collecting the NSX adapter, see NSX Account in VCF Operations

- To use Principal Identities authentication in VCF Operations you must have created a Principal Identity user in NSX.
- Ensure that you have the client certificate and the key to authenticate the Principal Identity users in VCF Operations.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**.
2. On the **Accounts** tab, click **Add**, and on the **Accounts Types** page, select **NSX**.
3. Configure the adapter instance.

| Option | Action |
|---|---|
| Name | Enter the name for the NSX instance as you want it to appear in VCF Operations. |
| Description | Enter any additional information that helps you manage your instances. |

4. Configure the connection.

| Option | Action |
|---|---|
| Virtual IP/ NSX | Enter the FQDN, the IP address, or the Virtual IP of the NSX. Both IPv4 address and IPv6 address formats are supported. |
| Credential | Select the credential that you want to use to sign on to the environment from the drop-down menu. To add new credentials to access the NSX environment, click the plus sign.<br>1. From the **Manage Credential** dialog, you can click the **Credential Kind** drop-down and select **NSX Client Certificate Crentials** or **NSX Credentials**.<br>The NSX Client Certificate allows you to use Principal Identities user or certificate-based client for authentication and the NSX Credential allows you to use local administrator or VMware Identity Manager for authentication.<br>2. Enter the credential details based on your selection.<br>For NSX Credentials, enter the following details.<br>• Credential Name - The name by which you are identifying the configured credentials.<br>• User Name - The user name of the NSX instance.<br>• Password - The password of the NSX instance.<br>For NSX Client Certificate Credentials, enter the following details.<br>• Credential Name - The name by which you are identifying the configured credentials.<br>• Client Certificate Data - Enter the value of the client certificate data associated with the principal user.<br>• Client Key Data - Enter the value of the client key data associated with the principal user. |

| Option | Action |
|---|---|
| Cloud Proxy/Group | Determine which VCF Operations cloud proxy/ group is used to manage the account. If you have multiple cloud proxies/ groups in your environment, and you want to distribute the workload to optimize performance, select the cloud proxy/ group to manage the adapter processes for this instance.<br>**Review and Accept Untrusted Certificates**<br>When you upgrade VCF Operations, the NSX adapter moves to a warning state and the data collection stops. This happens only when you have an adapter that presents a self-signed certificate, or a certificate signed by an untrusted Certification Authority.<br>To continue the adapter configuration, you must Validate the Connection, where you are prompted to review and accept the certificate.<br>**Note:**<br>If you have a multi-node cluster configuration, then you are prompted to review and accept the certificate for each node. |
| Log Operations | |
| Collect Logs | Select the **Activate Log Collection** checkbox to enable log collection. To control log volume, and other configuration details, see Configuring and Analyzing Logs. |
| Network Operations | |
| Network & Flow | Select the option to activate the network and flow.<br>Install the operations-network appliance from **Fleet Management** > **Lifecycle** to activate this option |
| Advanced Settings | |
| Exclude Resources from Monitoring | Select specific NSX resources that you want to exclude from monitoring in VCF Operations. Once the exclusion is applied, the monitoring for the specified resources is disabled.<br>**Note:**<br>Earlier the Management Pack for NSX would collect all the data and monitor all the resource kinds associated with the Management Pack, but now it allows you to exclude specific resources from monitoring. |
| Exclude Management Services from Monitoring | Select specific NSX management services that you want to exclude from monitoring in VCF Operations. Once the exclusion is applied, the monitoring for the specified services is disabled.<br>**Note:**<br>Earlier the Management Pack for NSX would collect all the data and monitor all the services associated with the Management Pack, but now it allows you to exclude specific services from monitoring. |
| Exclude Logical Router Services from Monitoring | Select the specific router service you want to exclude from monitoring in VCF Operations. Once the exclusion is applied, the monitoring for the specified services is disabled. |
| Auto Discovery | Set the **Auto Discovery** to True or False.<br>• **Auto Discovery - True** - Activates auto-discovery of the new objects added to the monitored system. By default, this field is set to True.<br>• **Auto Discovery - False** - Deactivates auto discovery, you must manually discover the objects from the system which you want to monitor. |

| Option | Action |
| --- | --- |
| Import Alerts from NSX | You can directly import alerts from NSX into VCF Operations by setting the **Import Alerts from NSX** field to **True**.<br>Depending on the number of alerts and the performance of the system, importing alerts into VCF Operations may take some time.<br>By default, this field is set to **False**. |

5. Click **Add** to save the configurations.

   The adapter instance is added to the list. Newly created NSX accounts do not start monitoring the data automatically and you must manually initiate the data collection.

6. On the **Accounts** tab, locate the NSX account, click the vertical ellipsis, and then click **Start Collecting All**.

Verify that the adapter is configured and is collecting data.

### Support for Principal Identities Authentication for NSX

VCF Operations supports authentication of Principal Identities (PI) using NSX . The Principal Identities (PI) are unique users in NSX who can create an object and ensure that the object can only be modified or deleted by the same identity. The authentication of principal identities is only supported through a client certificate. The principal identities authentication is local to NSX and it is possible to assign a predefined Role-based access control (RBAC) role to the principal identity.

Principal Identities are used by third-party applications or cloud management platforms such as Open stack, and Pivotal Container Services (PKS) to ensure that an administrator does not modify the NSX configuration which can generate a mismatch between their view of the NSX environment and the actual configuration.

## VCF Automation for All Apps Organization Account in VCF Operations

The VCF Automation for All Apps Organization management pack expands the operational capabilities available to users, helping partners effectively meter, price, and bill their cloud services using VMware's chargeback technology. It enables flexible segmentation of virtual environments to meet tenant requirements and supports various billing strategies. By offering accurate infrastructure monitoring and customizable pricing models, the solution ensures tenants have a transparent view of their resource consumption, making billing verification simple. Both service providers and tenants benefit from comprehensive reports, real-time alerts, and intuitive dashboards that display usage patterns, resource allocation, and pricing information.

#### Overview of the VCF Automation for All Apps Organization Management Pack

The Management Pack for VCF Automation for version 8.x enabled integration with VMware Aria Automation 8.x environments, providing cloud administrators with monitoring, alerting, reporting, metering, and pricing capabilities. With the strategic consolidation of VMware Cloud Director and VMware Aria Automation into VCF Automation 9.0, existing organizations will persist as VM Apps organizations, while newly created organizations will be categorized as All Apps organizations.

With the release of VCF, VCF Automation, VMware Cloud Director, and Supervisor functionality are integrated into a single product called VCF Automation 9.0. This consolidation empowers customers to effectively manage IT catalogs, multi-tenancy, and modern application development for both enterprises and service providers. When you upgrade your existing vRealize Automation 8.x environment to the latest VCF Automation 9.0 version, your existing organizations will remain unchanged and will be classified VM Apps organizations. Any new tenant created after the upgrade is included in the All Apps organization.

To support these enhancements, you must deploy VCF Automation for All Apps Organization in clean deployments where you are deploying an instance of VCF newly and you do not have VMware Aria Automation 8.x management pack deployed. One adapter can collect information for all the organizations and resources. For more information on Chargeback, see the topic, Performing VCF Automation Based Multitenancy in VCF Operations.

If you have a VMware vSphere Foundation license, the VCF Automation for All Apps Organization integration is not available.

## Considerations for Deploying the Management Pack for VCF Automation for All Apps Organization

The integration and upgrade is based on whether the VMware Aria Automation 8.x management pack was previously installed and whether VCF 9.0 is installed as a clean deployment or an upgraded environment.

**Deploying the VCF Automation 9.0 Management Pack in VCF 9.0**

- VCF 9.0 must be a clean deployment and you should not have VMware Aria Automation 8.x management pack configured.
- **VCF Automation for All Apps Organization** adapter does not support upgraded installations.

If you have a VCF license, the VCF Automation for All Apps Organization adapter is automatically created after VCF Automation is installed. You can deploy VCF Automation in the following two ways:

- Using VCF Operations. For more information, see Deploying VCF Automation as a Day-N Operation.
- Using the VCF Installer. For more information, see Deploy Components by Using VCF Installer to Complete the Converging to VCF Process.

### VCF Automation for All Apps Organization Metrics and Content

To see a list of metrics and content for the VCF Automation for All Apps Organization management pack, go to the VCF Automation for All Apps Organization tile by clicking the **Repository tab** under **Administration** > **Integrations**.

# VCF Automation for VM Apps Organization Account in VCF Operations

VCF Automation for VM Apps Organization management pack enhances the VCF Operations platform by providing cloud-aware visibility into infrastructure operations. This integration allows administrators to monitor the health, performance, and capacity risks of connected cloud environments. Through this functionality, users can import and synchronize cloud accounts into the VCF Operations interface, gaining better insight into cloud zone performance. It also supports efficient workload placement for VMs within managed clusters and offers tools to diagnose and resolve issues with vSphere endpoints directly from the operations dashboard.

You can use VCF Automation for VM Apps Organization to perform some of the following key tasks:

- Gain visibility into the performance and health of cloud zones integrated with VCF Operations.
- Import and synchronize existing cloud accounts from VCF Automation to VCF Operations.
- Manage the workload placement of VMs that are part of the clusters managed by VCF Automation.
- Integrate and troubleshoot vSphere endpoint issues associated with VCF Automation using the VCF Operations dashboard.

  **Note:**

  In this release only vSphere endpoints are supported.

## Configuring the Management Pack for VCF Automation for VM Apps Organization

If you have a VCF license, you can deploy VCF Automation for VM Apps Organization from the VCF Operations repository. This adapter works with a greenfield deployment of VCF 9.0 when you have already installed and configured the VMware Aria Automation 8.x Management Pack.

You must know the following details from the steps in the VM Apps Organization Portal:

- Organization ID
- Credential name and the Refresh Token

For more information, see the topic, Create a Service Account and Get a Refresh Token in VCF Automation for VM Apps.

If VMware Aria Automation 8.x Management Pack was already configured in Aria Operations, and you have upgraded to VCF 9.0, the management pack functions without requiring changes. This is provided that the VMware Aria Automation 8.x APIs remain compatible with VCF Automation 9.0 issued tokens and Cloud Services Platform APIs.

If you are deploying a new VCF 9.0 instance, and you previously had VMware Aria Automation 8.x Management Pack configured, then you must activate theVCF Automation for VM Apps Organization adapter.

1. From the left menu, click **Administration** > **Integrations**.
2. On the **Repository** tab, find the **VCF Automation for VM Apps Organization** tile.
3. Click the **Activate** button. Click **Yes** in the confirmation dialog box.
4. Fill the FQDN of the VCF Automation server. Enter the organization ID from the VM Apps Organization Portal in the **VCF Automation Org ID** field.
5. Set **Auto Discovery** to true.
6. Click the **+** button next in the **Credential** field. Select **Tenant Scoped Service Account** from the drop-down, and enter the Credential Name and the Refresh Token.
7. From the **Cloud Proxy/ Groups** drop-down menu, select the cloud proxy group.
8. Click **Advanced Settings**. From the **User Count** drop-down menu, select the number of user resources to be imported from VCF Automation. The User Count options are 20, 100, 200, 300, 400, and All Users.
9. Click **OK**.
10. Click the **Add** button to add the adapter instance to VCF Operations.

## Advanced Workload Placement for Allocation Model

VCF Operations supports allocation aware advanced workload placement between VCF Automation for VM Apps Organization tenant and VCF Operations for initial placement of virtual machines. The placement recommendation is based on allocation settings that are defined in the VCF Operations policy. The advanced workload placement awareness for allocation works with the existing demand model.

### Need for Allocation Model Awareness

The advanced workload placement based on demand model, depends on the actual demand for resources in a cluster and datastore. If the allocation is based only on the utilization of resources, then it might result in over allocation or over provisioning of resources in clusters. To avoid this, VCF Operations provides allocation model awareness. Allocation model awareness addresses issues related to over allocation or over provisioning by providing you the option of setting the appropriate overcommit ratios in the VCF Operations policy.

The advanced workload placement feature uses the demand model by default and cannot be turned off. To activate the allocation model in addition to the demand model, in VCF Operations configure the appropriate overcommit ratios in policy settings for the preferred clusters, datastores, and datastore clusters.

### Prerequisites

- VCF Operations is configured as an endpoint in VCF Automation for VM Apps Organization tenant. This happens automatically in case of VCF Operations.
- Advanced placement policy in the cloud zone must be activated.
- vCenter Cloud account instance on which the initial provision is done should be same acrossVCF Operations and VCF Automation for VM Apps Organization tenant.
- Overcommit ratios in VCF Operations policy must be configured for the following:
  - For CPU and Memory overcommit ratio - Cluster Compute Resource.
  - For Disk overcommit ratio - Datastore and Datastore Cluster.

### How to Activate the Advanced Placement Policy

To activate the advanced placement policy, in VCF Automation Cloud Assembly Service, navigate to **Infrastructure** > **Cloud Zone** > **Summary** tab and set the placement policy to **ADVANCED**.

**Note:**

If VCF Operations returns no recommendations, then under the placement policy, you can specify if you want VCF Automation for VM Apps Organization tenant to fall back to its default placement using the toggle option.

**How to Activate Allocation Awareness in Advanced Workload Placement Feature**

To activate Allocation awareness in VCF Operations perform the following actions.

1. From the left menu, click **Infrastructure Operations** > **Configurations**, and then click the **Policy Definition** tile.
2. Select the Active policy which is assigned to the Cluster Compute resource under Cloud Zones and make the required changes.
3. Click **Edit Policy** and navigate to the **Capacity** tile.
4. Select the **Object Type** as Cluster Compute Resource and activate the Allocation Model.
5. Set the overcommit ratio as per your requirement and click **Save**.
6. Repeat Step 3 to Step 5 for datastore cluster, vSAN datastores and local datastores.

After the configuration is completed, VCF Automation makes a provisioning request to VCF Operations , and the advanced workload placement engine calculates the recommendation and shares it with VCF Automation for VM Apps Organization tenant. To know the changes after the configuration, view the Allocation metrics and Demand metrics for the cluster.

**Note:**
The allocation model awareness enhancement is limited to advanced workload placement feature. This capability is not extended to workload optimization feature.

## Object Types

VCF Automation brings in cloud accounts and their relationships from VCF Automation for VM Apps Organization tenant into VCF Operations for operational analysis. You can use the following items in the virtual infrastructure as object types in VCF Operations.

- Cloud Zone
- Blueprint
- Project
- Deployment
- Cloud Account
- User
- Organization
- Cloud Automation Services World

## Workload Placement

In VCF Operations , you can configure VCF Automation for VM Apps Organization tenant instances to work with VCF Operations instances. Using VCF Operations you can monitor the placement of existing workloads and optimize the resource usage.

- Verify that the user has privileges of Organizational Owner and Cloud Assembly Administrator set in VCF Automation for VM Apps Organization tenant.
- You must know the vCenter credentials and have the necessary permissions to connect and collect data.
- Verify that VCF Automation for VM Apps Organization tenant is activated from **Administration** > **Integrations** in VCF Operations. See, Configuring the Management Pack for VCF Automation for VM Apps Organization.
- VCF Operations must have the same vCenter Cloud Account configured to match with VCF Automation for VM Apps Organization tenant.
- Ensure that integration is activated for VCF Operations and VCF Automation for VM Apps Organization tenant.

1. Click the Workload Placement tab under **Capacity** > **Optimize**.
2. Click the **View** filter drop-down menu and select the **VRA Managed** objects.

   All the Cloud Zones related to the vCenter are displayed in VCF Operations.
3. Click the **Cloud Zone** you want to optimize.
4. Based on the operational intent, click **Optimize Now**.

   The system creates an optimization plan, which depicts BEFORE and (projected) AFTER workload statistics for the optimization action.
5. If you are satisfied with the projected results of the optimization action, click **NEXT**.
6. Review the optimization moves, then click **BEGIN ACTION**.

   In the scope of VCF Automation for VM Apps Organization tenant integration, VCF Operations sends a move migration request directly to VCF Automation for VM Apps Organization tenant. In the earlier versions, the migration request was sent to the vCenter.

To verify that the optimization action is complete, select **Administration** from the left menu, and click **Recent Tasks** . In the **Recent Tasks** page, use the Status function on the menu bar to locate your action by its status. You can also search using a range of filters. For example, first filter on Starting Time and scroll to the time when you began the action, then select the Object Name filter. Finally, enter the name of one of the VMs in the rebalance plan.

## Pricing for VCF Automation for VM Apps Organization tenant Components in VCF Operations

After you integrate VCF Automation for VM Apps Organization tenant private cloud adapter instances with VCF Operations you can calculate the cost of deployments, projects, and virtual machines of the selected cloud adapter. Pricing provides an overview of the costs related to the cloud environment, cloud resources, and the costs associated with the project.

### How the Pricing Works in VCF Automation for VM Apps Organization Tenant

- VCF Operations understands the constructs defined in VCF Automation for VM Apps Organization tenant and calculates the CPU, RAM, Storage and Additional prices for Projects, Deployments, and virtual machines.
- A single project can have multiple deployments and a single deployment can have multiple virtual machines associated with the deployment.
- Pricing for multiple virtual machines associated with the deployment is the sum of all the resources associated with individual virtual machines.
- If a single project has multiple deployments, then the project pricing is equal to the sum of individual deployments. The deployment can have multiple virtual machines and resources associated with it.
- On day one, the pricing is equal to the cost of resources defined in VCF Operations.
- On day two, the price is calculated using the following formula.
  - Cost of resources for the present day – Cost of resources for the previous day.
- If in case the pricing does not happen as per the definition, then the partial price is set to true, and the pricing is calculated based on the previous days price.
- In VCF Operations, the following new dashboards are included to view the pricing details for the VCF Automation for VM Apps Organization tenant instances.
  - Cloud Automation Environment Overview
  - Cloud Automation Project Cost Overview
  - Cloud Automation Resource Consumption Overview
  - Cloud Automation Top-N Dashboard

### Data Collection Enhancements in VCF Automation for VM Apps Organization Tenant for Pricing in VCF Operations

The following enhancements have been made for the data collection process from VCF Automation for VM Apps Organization tenant for pricing purposes.

- Collect cloud zones with relation to clusters and resources pools from VCF Automation for VM Apps Organization tenant to VCF Operations.
- Collect Projects from VCF Automation for VM Apps Organization tenant with relation to deployments.
- Include project, cloud zone, and blueprint as properties in virtual machines that are deployed in VCF Automation for VM Apps Organization tenant.

#### Upfront Price Support for VCF Automation for VM Apps Organization Tenant Private Cloud Components

VCF Operations supports upfront pricing for VCF Automation for VM Apps Organization in the following ways:

- VCF Operations uses rate cards to provide upfront cost estimates of catalog items just before deployment.
- VCF Automation for VM Apps Organization tenant retrieves the deployment cost and estimated cost from VCF Operations.
- VCF Automation for VM Apps Organization tenant user interface allows you to customize the pricing policies and assign them to the projects or cloud zones.
- If VCF Automation for VM Apps Organization tenant does not specify the pricing policy, then the price is calculated using the VCF Operations cost calculation policy.
- If a custom pricing policy is set for a price calculation, then the deployment and upfront catalog price computation is done as per the custom policy.

#### Upfront Price Support for VMware Cloud on AWS Resources

VCF Operations supports upfront pricing for VMware Cloud on AWS resources in the following ways:

- VCF Operations supports upfront pricing for VMware Cloud on AWS only if rate-based pricing is configured in VCF Automation for VM Apps Organization tenant for VMware Cloud on AWS resources.
- VCF Operations does not support cost-based computation for VMware Cloud on AWS resources.

## Managing Public Cloud Endpoints with VCF Automation for VM Apps Organization Tenant Integration

With the VCF Operations management pack, you can monitor deployments made to public cloud endpoints such as Amazon Web Services (AWS), Google Cloud Platform (GPC), and Microsoft Azure. You can monitor the performance, health, utilization, and availability attributes of deployments made to public cloud endpoints.

This integration supports the VCF Operations management packs for public clouds – MP for AWS, GCP, and Azure. Hence, the public cloud management packs are a prerequisite for this enhancement.

VCF Operations will display the VCF Automation for VM Apps Organization tenant deployed by public cloud resources as long as the same resources are also monitored by VCF Operations for the respective public cloud management packs.

This enhancement also shows all the cloud accounts and cloud zones that are part of public cloud end points.

> **Note:**
>
> To monitor the VCF Automation for VM Apps Organization tenant resources deployed to AWS, GCP, and Azure, you must ensure that the cloud accounts are configured in both VCF Automation for VM Apps Organization tenant and VCF Operations.

#### Import Account Functionality

Users may import AWS, Azure, and vCenter accounts automatically through the **Import Account** option. However, for the GCP account you should manually add the cloud account through **Add Account** option. The credential used to configure the adapter must match the one used in VCF Automation for VM Apps Organization tenant. The traversal specification of VCF Automation for VM Apps Organization tenant has been enhanced to include details about AWS, Azure, and GCP accounts.

## Cloud Zones in VCF Operations

Cloud zones help you to group a set of compute resources and assign capability tags to the zone. The cloud zone is based on accounts/regions, so you must have at least one cloud account configured before you can create a cloud zone. Cloud zones define where and how blueprints configure deployments. You can have one or many cloud zones assigned to each project based on priority and limits.

### How Cloud Zones Work

After you integrate VCF Automation for VM Apps Organization tenant with VCF Operations, you can retrieve cloud zones into VCF Operations. The **Cloud Zones** option is hidden from the user until the integration with VCF Automation is activated from the integration page under **Administration** > **Integrations**.

The Cloud Zones option is activated in VCF Operations , only if the following conditions are met.

- VCF Automation for VM Apps Organization tenant management pack is integrated successfully in VCF Operations.
- VCF Automation for VM Apps Organization tenant objects are discovered in VCF Operations.
- VCF Automation for VM Apps Organization tenant accounts and Aria Operations vCenter Cloud Accounts are synchronized.

All the Cloud Zone objects which are existing in VCF Automation for VM Apps Organization tenant environment, are discovered inVCF Operations. Cloud zones, whose dependent clusters are not discovered in VCF Operations, are not represented in Capacity Overview, Reclaim, and Workload Optimization pages.

# Ping Account in VCF Operations

In VCF Operations, you can configure the ping functionality to verify the availability of end points that exist in your VMware Cloud Foundation platform. The ping functionality is configured at the adapter instance for IP addresses, group of IP addresses, and FQDN's.

Activate the Ping adapter before you configure it.

- If you have multiple adapter instances running on different collectors and both are pinging the same address, you can still get statistics from both the adapter instances for the same IP.
- The FQDN names are checked for validity, the FQDN validation relies on RFC1034 and RFC1123, and only top level domains of the internet are validated. The `.local` domain is not supported as it does not fall into the list of top-level domains in the Domain Name System (DNS) of the Internet.

1. From the left menu, click **Administration** > **Integrations**.
2. In the Accounts tab, click **Add**.
3. Click **Ping**.
4. If the management pack has not been installed previously, Click **Yes** in the dialog box to install the management pack.
5. Configure the Ping adapter instance.

| Option | Description |
|---|---|
| **Name** | Enter a name for the adapter instance. |
| **Description** | Enter the description of the adapter instance. |
| **Unique Name** | Specify the name for the adapter instance. You can use the name to view the metrics published for the adapter instance. |
| **Address List** | Specify the IP address, IP address range, and the FQDN which must be pinged. |
| **Configuration Filename** | Specify the name of the configuration file. The configuration file contains the IP addresses, CIDR information, and FQDN details as a comma-separated file. |
| **Collector / Group** | Select the collector from which this adapter instance must run. |
| **Validate Connection** | Click to check whether the connection is successful or not. |
| **Advanced Settings** | To configure the advanced settings, click the drop-down menu. |

| Option | Description |
|---|---|
| **Wait Interval Time (second)** | Specify the time interval in seconds to wait before running the next batch. Range: 0-300 seconds. |
| **Batch Size** | Specify the number of request packets to send to each target. Range: 20-100. |
| **Interval (millisecond)** | Specify the time the fping waits between successive packets to an individual targets. Greater or equal to 2000 milli seconds. |
| **DNS Name Resolve Interval (minute)** | Specify the time at which you must resolve the DNS name for the next cycle. Minimum value is 15 minutes. |
| **Packet Size (byte)** | Specify the byte size of the packet when you ping. Range: 56-65536 bytes. |
| **Don't Fragment** | Select **False** to fragment the packet and **True** to not fragment the packet. |
| **Generate FQDN Child IPs** | Select **True** to create IP objects by resolved names and add as child of FQDN. |

6. Click **Add**.

   The adapter instance is added to the list. Newly created ping accounts do not start monitoring the data automatically and you must manually initiate the data collection.

After you configure the Ping adapter instance, you can view the adapter details from **Administration** > **Integrations** > **Repository**.

# VCF Operations for networks Account in VCF Operations

The VCF Operations for networks adapter activates integration of VCF Operations with VCF Operations for networks. VCF Operations for networks provides network visibility and analytics to minimize risk during application migration, optimize network performance, manage and scale NSX, and Kubernetes deployments.

- Cloud Integration can be done, when VCF Operations for networks and VCF Operations services are present in the same organization.
- For the cloud integration to be possible, you must have VCF Operations for networks and VCF Operations services in the same geographical location.

This adapter gets problem events from VCF Operations for networks and publishes the alerts in VCF Operations. Alerts are mapped correctly to the common objects between VCF Operations for networks and VCF Operations. Common objects supported in this adapter are vCenter and NSX For the common objects, VCF Operations supports launch-in-context to VCF Operations for networks. This allows the user to perform deep network troubleshooting with the VCF Operations for networks as the context.

The VCF Operations for networks adapter only supports VCF Operations for networks versions 5.2 and above. The VCF Operations for networks adapter can be installed and configured with the on-prem versions of VCF Operations. The VCF Operations for networks adapter does not support cross platform configuration, it should be on-prem VCF Operations to on-prem VCF Operations for networks.

## Configuring VCF Operations for networks

Configure an instance of the VCF Operations for networks in VCF Operations.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**.
2. From the **Accounts** tab in the **Integrations** page, click **Add Account** and then select the **VCF for Networks** card. You can also activate the management pack from the **Repository** tab, where you will find the card in the **Available Integrations** section. After the management pack is activated, click **Add Account**.
3. Configure the adapter instance.

| Option | Description |
|---|---|
| **Name** | Enter a name for the adapter. |

| Option | Description |
|---|---|
| **Description** | Enter a description. |
| **FQDN/IP** | The FQDN or the IP address of VCF Operations for networks.<br><br>**Note:**<br><br>It is recommended to use the IP address during the VCF Operations for networks instance creation.<br><br>If a VCF Operations for networks instance was configured in VCF Operations 8.18.x using an FQDN instead of an IP address, an automated migration occurs during the upgrade to VCF Operations 9.1.<br><br>• A new adapter instance is automatically created in the **Integrations** > **Accounts** page using the IP address of the server.<br>• The original FQDN-based instance is placed into a stopped state.<br>• All existing objects, data, and relationships are automatically migrated to the new IP-based instance as child objects, ensuring no data loss.<br>• The stopped FQDN-based instance is no longer required and can be safely removed from VCF Operations. |
| **Credential** | Select and add the credential you want to use to sign on to the environment from the drop-down menu. To add new credentials to access the environment of this management pack, click the plus sign.<br><br>• **Credential Kind**. Select and configure the Credential Type. You can select either the Local, LDAP, or VIDM<br><br>**Note:**<br><br>This Management pack supports only the Local, LDAP, and vIDM users that are added in the **User Management** settings of VCF Operations for networks.<br><br>– Local - Network Credentials. Enter the credential name, user name of the local user configured in VCF Operations for networks, and password.<br>– LDAP - Network Credentials. Enter the credential name, LDAP domain configured in VCF Operations for networks, LDAP user name, and LDAP password.<br>– vIDM - Network Insight Credentials. Enter the credential name, vIDM FQDN/IP integrated with VCF Operations for networks, vIDM user name, and vIDM password for that vIDM user.<br>**Credential Name**. |
| **Cloud Proxy/ Group** | Select the required cloud proxy group . |
| **Validate Connection** | Test Connection should be successful. |

4. The VCF Operations for networks instance collects events based on common data sources between VCF Operations and VCF Operations for networks. When you deactivate the **Import problem events as based on common data sources** option, all the events are imported into the VCF Operations.
5. You can collect user-defined events of VCF Operations for networks as notifications in VCF Operations. To do so, activate the **Import User defined events as Notifications**.
6. Select the severity of the problem events you want to import. By default, all the problem events with moderate and critical severities are imported.
7. Click **Add**.

   The VCF Operations for networks instance is added to the list. Newly created VCF Operations for networks accounts do not start monitoring the data automatically and you must manually initiate the data collection.

## Viewing Dropped Flow Alert for Check Point and Palo Alto

You can view dropped flow alerts for Check Point and Palo Alto devices in VCF Operations.

- Ensure VCF Operations for networks is installed in VCF Operations.
- Ensure log management is configured as a syslog server in Check Point and Palo Alto devices.
- Ensure ports 514 and 1514 are open so that they can communicate with log management.

Before VCF 9.1, the Check Point and Palo Alto dropped flow alerts were raised in VCF Operations for networks. Starting with VCF 9.1, you do not need to add the 9.1 version of the log management data source in VCF Operations for networks to receive the Check Point and Palo Alto dropped flow alerts. These alerts are raised and can be viewed in VCF Operations.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configuration**.
   - To view the alert definitions, click **Alert Definitions**, and filter the alerts with the object type set to **Log Fallback Object**. For more information, see Alert Definitions in VCF Operations.
   - To view the symptom definitions, click **Symptom Defitions**, and then click **Logs**. For more information, see Symptom Definitions in VCF Operations.

   The following dropped flow alerts are available:

   - Dropped flows are detected on a Check Point device through VCF Operations for logs.
   - Dropped flows are detected on a Palo Alto device through VCF Operations for logs.
2. To view raised alerts, in the left navigation pane, click **Alerts**, group the alerts by object type, and expand the **Log Fallback Object**.

   **Note:**

   When log management reports a dropped flow received from a Check Point or a Palo Alto device, VCF Operations will raise an alert.
3. Click on an alert to view alert details and check for symptoms.

   For example, the alert for the Check Point device displays the following symptom message: “The Warning symptom 'Dropped flows are detected on Check Point device through log management has been observed on Log Fallback Object." For more information, see Understanding Alerts in VCF Operations.
4. In the **Recommendations** section of the alert, click **analyze logs** to open the log analysis page with the query that is required to filter the dropped flow log messages.
5. In the **Stream** section, expand the log entry to view the required field information for the dropped flow. For more information, see Configuring and Analyzing Logs.

The dropped flow alerts for the Check Point or Palo Alto device are raised in VCF Operations, and the associated log messages are available for analysis in log management.

# vSphere Supervisor Monitoring

The management pack that is introduced in VCF 9.0 helps you monitor the resource utilization and performance of vSphere Supervisor and VKS clusters and resources by using VCF Operations. This is an internal, native management pack that is activated by default. Data collection is enabled through the vCenter integration.

## What is vSphere Supervisor Monitoring

VCF 9.0 introduces an integrated monitoring solution in the form of the vSphere Supervisor management pack to track Kubernetes resource allocation, availability, and performance.

vSphere Supervisor management pack is a native, but internal management pack which is automatically installed when you configure the vCenter integration. This pack enables automated resource detection and monitoring specifically for vSphere Supervisor and vSphere Kubernetes Service VKS clusters. When you enable a setting in the vCenter integration, VCF Operations automatically detects and creates vSphere Supervisor adapter instances for streamlined monitoring. For more details, see Enabling Monitoring for vSphere Supervisor.

Previously, the Management Pack for Kubernetes monitored Kubernetes clusters using a pull-based model. The vSphere Supervisor management pack monitors vSphere Supervisor and VKS clusters using push based metric collection. Unlike the traditional pull-based approach, the vSphere Supervisor adapter uses Telegraf and the data is pushed directly to a Cloud Proxy. For more information on Telegraf, see, Monitoring Application Services using Product-Managed Telegraf. The Cloud Proxy acts as an intermediary to store and forward data, ensuring reliability even if temporary network disruptions occur. To see a list of metrics collected, go to the topic, vSphere Supervisor Metrics.

### How vSphere Supervisor Monitoring Works

The Application Monitoring adapter is responsible for collecting metrics and organizing the resource inventory. For every Cloud Proxy which is configured in VCF Operations, an Application Monitoring adapter is automatically created for it.

Telegraf collects metrics from different Kubernetes objects inside the vSphere Supervisor and VKS clusters and forwards them to the Cloud Proxy. Monitoring of Kubernetes objects such as vSphere Pods and containers is supported. vSphere Pods are only supported with Supervisors that are configured with NSX as the networking stack. For vSphere Supervisor, monitoring of these objects is enabled by default. For VKS clusters, you must enable it.

During the first collection cycle, certificates are created, and the endpoint details are sent to the vSphere Supervisor. The vSphere Supervisor adapter ensures that metrics are directed to the appropriate Cloud Proxy.

Once the Application Monitoring adapter receives metrics, it organizes and stores the inventory. If needed, you can switch to any other Cloud Proxy, and the vSphere Supervisor adapter will automatically update the endpoint details.

## Key Features of the vSphere Supervisor Management Pack

The vSphere Supervisor management pack provides enhanced observability and lifecycle management for VKS.

| | |
|---|---|
| **Push-Based Metrics Collection** | The vSphere Supervisor adapter introduces a push-based model that leverages Telegraf, enabling improved efficiency in metric collection. The metrics are pushed into a Cloud Proxy. This ensures faster and more reliable metric collection. |
| **Seamless Integration** | Enabling the vSphere Supervisor management pack is simple, and allows for automatic detection and configuration of Kubernetes clusters within vCenter instances. |
| **Support for vSphere Supervisor and VKS Clusters** | • vSphere Supervisor **:** Serves as a platform for deploying VKS clusters and ensure overall system stability.<br>• VKS clusters**:** Streamline Kubernetes clusters that host application workloads and run user-deployed applications.<br>The vSphere Supervisor management pack can monitor both VKS clusters and vSphere Supervisor, ensuring quick identification of performance issues. |
| **Automated Cluster Discovery** | When enabled, the vSphere Supervisor adapter identifies all the vSphere Supervisor and VKS clusters in a vCenter environment and creates the necessary Application Monitoring adapter instances for monitoring. |

| | |
|---|---|
| **Enhanced Observability with Dashboards and Metrics** | The vSphere Supervisor adapter provides details about the vSphere Supervisor and VKS cluster infrastructure, and applications running in the VKS clusters. |

## Steps to Monitor vSphere Supervisor and Resources

Use VCF Operations to enable the vSphere Supervisor management pack, and monitor and troubleshoot vSphere Supervisor and VKS clusters.

### Enabling Monitoring for vSphere Supervisor

You enable or disable vSphere Supervisor monitoring when configuring the vCenter cloud account integration in VCF Operations. The vSphere Supervisor internal management pack is enabled or disabled based on this setting. One vCenter cloud account can have multiple Supervisors enabled. When the setting is enabled, an adapter instance for each supervisor is automatically created and monitored. When it is disabled, the adapter instance is still available, but metrics are not collected.

- Ensure that you are logged in to VCF Operations with the required permissions to add or edit a vCenter cloud account.

1. From the left menu, click **Administration** > **Integrations**.
2. On the **Accounts** tab, click **Add**. On the Accounts Type page, click **vCenter**. For more information about configuring a vCenter cloud account, see the topic, Configure a Cloud Account.
3. Alternatively, select an existing vCenter account and click **Edit** from the vertical ellipsis.
4. Expand **Advanced Settings**.
5. Verify that the value of **Enable vSphere Supervisor Collection** is set to true. This is the default setting.
6. Once you have configured the rest of the settings, click **ADD**.

After enabling vSphere Supervisor monitoring the following settings are automatically configured:

- vSphere Supervisor sends data to the Cloud Proxy VM running the Application Monitoring adapter.
- The Telegraf package defines which metrics are collected and how often they are sent.

To verify that the adapter is collecting data, go to **Inventory (Detailed View)** > **Integrations** > **vSphere Supervisor** and check the **Summary** tab in the **Supervisor World** object.

To see the vSphere Supervisor adapters which are configured and collecting metrics, go to **Infrastructure Operations** > **Dashboards and Reports** > **Inventory** and look for the **vSphere Supervisor** dashboards.

### Enabling Monitoring for VKS Clusters

VCF 9.1 leverages the VKS add-on management system to install Telegraf and Prometheus in VKS clusters to enable automated monitoring of VKS Clusters. For more information on the VKS add-on management system, see Installing Standard Packages on VKS Clusters.

#### Monitoring Prerequisites for VKS Clusters

Before you can enable monitoring for VKS clusters, ensure that the following prerequisites are met in your VCF environment.

- Work with the VCF Operations administrator to ensure that vCenter and its associated Supervisor are set up for monitoring in VCF Operations . See Steps to Monitor vSphere Supervisor and Resources.
- Ensure that the Metrics Aggregator VCF Service is installed in the Supervisor. This service is installed by default with VCF Automation. You can verify that the service is installed correctly using the Provider Console in VCF Automation. See Using Services with VCF Automation.
- Supervisor must have the addon repository installed that supports the automated installation of Telegraf and Prometheus addons for monitoring purposes. Ensure the required Telegraf and Prometheus AddonRepository, Addon, AddonConfigDefinition CR's are available in Supervisor. See Managing Addons in VKS Clusters for more information.

After the prerequisites are met, any new VKS cluster is automatically monitored. If you want to disabled monitoring, see Disable Automated Monitoring on VKS Clusters using VCF Automation or Disable Monitoring on VKS Clusters using VCF CLI.

#### Verify Authentication and Security

Supervisor generates the certificates for each Telegraf instance in a VKS Cluster. These certificates are rotated by the cert-manager running on the Supervisor and automatically updated in the VKS Cluster. Metrics Aggregator terminates the TLS connection from the VKS Cluster, thus securing the communication between the Supervisor and VKS clusters. Metrics Aggregator uses the certificates provided by Cloud Proxy for communication between Metrics Aggregator and Cloud Proxy. Cloud Proxy terminates the TLS Connection thereby securing communication between the Supervisor and Cloud Proxy.

For more information on monitoring VKS Clusters, see Monitoring VKS Clusters Using VCF Operations.

### Disabling Monitoring for the Supervisor

You can disable monitoring for Supervisors from VCF Operations. After you disable monitoring, the objects are not displayed in the Object Relationship chart in the Inventory when you browse to the vSphere Supervisor object. The endpoint is removed from the Telegraf configuration of the Supervisor.

1. Go to the **Inventory Management** tile in the **Inventory** > **Configurations**.
2. In the search tab, enter the name of the Supervisor for which you want to disable monitoring. This is a quick way to find the object. Alternately, you can browse the list of objects and locate the objects.
3. Click the edit icon to edit the object. The **Edit Object** dialog box opens.
4. From the drop-down, select **No** for the **Enable Monitoring** setting under the **Advanced Settings**. The default value is **Yes**.
5. Click **OK**.

### Viewing Supervisor Metrics

This table lists the metrics which the Supervisor management pack collects. Go to the **Metrics** tab in the **vSphere Supervisor** object page by navigating to **Administration** > **Integrations** > **Repository** to view their details.

#### Supervisor Metrics

A list of the Supervisor metrics available in VCF Operations is in the following table:

| Object | Element | Metric | Type | Unit |
|---|---|---|---|---|
| Container | CPU | Usage | Metric | Millicores |
| Container | CPU | Throttled | Metric | % |
| Container | CPU | Usage | Metric | % |
| Container | CPU | Requests | Property | Millicores |
| Container | CPU | Limits | Property | Millicores |
| Container | Memory | Usage | Metric | MB |
| Container | Memory | Usage | Metric | % |
| Container | Memory | Limits | Property | MB |
| Container | Memory | Fail Count | Metric | |

## Viewing vSphere Supervisor Dashboards

When the vSphere Supervisor management pack is enabled, you can view the metrics and resource information in VCF Operations using the three types of dashboards.

### Where You Find the vSphere Supervisor Dashboards

Go to **Infrastructure Operations** > **Dashboards and Reports** > **Inventory**. Expand the **All** folder and look for the **vSphere Supervisor** dashboards.

### Types of vSphere Supervisor Dashboards

- Kubernetes Inventory
  - Infrastructure details in your vSphere Supervisor, via nodes.
  - Pod and container status via namespace.
  - VKS Clusters lifecycle metrics.
- Kubernetes Performance
  - CPU and memory usage.
  - vSphere Supervisor and VKS Clusters performance.
- vSphere Supervisor
  - Monitor the critical components of the vSphere Supervisor.

### Using the vSphere Supervisor Dashboards

Together, these dashboards offers the following capabilities:

- High-Level Cluster Overview
  - The dashboard offers a summary of cluster health, showing key metrics such as CPU usage, memory consumption, and node availability.
  - You can quickly spot clusters with performance bottlenecks before diving into detailed analysis.
- Drill-Down Approach for Root Cause Analysis
  - If an issue is detected at the cluster level, you can navigate into child objects such as namespaces, nodes, and pods to pinpoint the source.
  - Example: If CPU throttling is detected at the cluster level, users can filter to see which namespaces or pods are consuming excessive CPU.
- Real-Time Monitoring with Push-Based Data Collection
  - Unlike traditional pull-based methods, metrics are pushed to the Cloud Proxy in real time, allowing for faster detection of performance spikes.
  - Users can correlate metrics over time, helping them understand trends that may lead to potential failures.
- Supervisor and Guest Cluster Insights
  - The Supervisor Dashboard monitors critical lifecycle components. If a Supervisor goes down, it may impact all associated VKS Clusters.
  - You can see which clusters are affected and take corrective action immediately.
- Debugging Pods and Containers
  - The dashboard provides alerts on failed pods, frequent container restarts, and out-of-memory (OOM) errors.
  - You can filter by node or namespace to isolate problematic workloads.

### Mapping Supervisor and VKS Cluster Nodes to VM and Node objects

All Kubernetes Nodes of the Supervisor or VKS clusters are represented in VCF Operations as two different objects.

1. As a Kubernetes Node that is created based on metrics that are collected through Telegraf.
2. As a vCenter VM or ESX host created based on inventory and metrics that are collected from vAPI and the ESX host.

These objects will be mapped to each other so that the correlation is clear.

Tthe following mappings are valid for the Supervisor:

- Supervisor Control Plane VM -> Node (control plane)
- ESX host - Node(worker)
- ESX host - Node(worker)

Following are example mappings for VKS clusters:

- VM -> Node (control plane)
- VM -> Node (worker)
- VM -> Node (worker)

# Configuring and Managing Policies

To create a policy, you can inherit the settings from an existing policy, and you can modify the settings in existing policies if you have adequate permissions. After you create a policy, or edit an existing policy, you can apply the policy to one or more groups of objects.

## Policies

A policy is a set of rules that you define for VCF Operations to use to analyze and display information about the objects in your environment. You can create, modify, and administer policies to determine how VCF Operations displays data in dashboards, views, and reports.

### How Policies Relate to Your Environment

VCF Operations policies support the operational decisions established for your IT infrastructure and business units. With policies, you control what data VCF Operations collects and reports on for specific objects in your environment. Each policy can inherit settings from other policies, and you can customize and override various analysis settings, alert definitions, and symptom definitions for specific object types, to support the service Level agreements and business priorities established for your environment.

When you manage policies, you must understand the operational priorities for your environment, and the tolerances for alerts and symptoms to meet the requirements for your business critical applications. Then, you can configure the policies so that you apply the correct policy and threshold settings for your production and test environments.

Policies define the settings that VCF Operations applies to your objects when it collects data from your environment. VCF Operations applies policies to newly discovered objects, such as the objects in an object group. For example, you have an existing VMware adapter instance, and you apply a specific policy to the group named World. When a user adds a new virtual machine to the vCenter instance, the VMware adapter reports the virtual machine object to VCF Operations. The VMware adapter applies the same policy to that object, because it is a member of the World object group.

To implement capacity policy settings, you must understand the requirements and tolerances for your environment, such as CPU use. Then, you can configure your object groups and policies according to your environment.

- For a production environment policy, a good practice is to configure higher performance settings, and to account for peak use times.
- For a test environment policy, a good practice is to configure higher utilization settings.

VCF Operations applies the policies in the priority order, as they appear in the priority column. When you establish the priority for your policies, VCF Operations applies the configured settings in the policies according to the policy rank order to analyze and report on your objects. You must have privileges to access specific features in the VCF Operations user interface. The roles associated with your user account determine the features you can access and the actions you can perform. To set and change the priority of any active policy complete the following steps:

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.
   In the **Policy Definiton** page, click the horizontal ellipsis, and click **Reorder Policies**.

   **Note:**
   The Reorder Policies option is activated only if there is more than one active policy.
2. In the Reorder Policies window, select the policy and drag it up or down to change the priority.
3. Click **ok** to save the changes made to the priority.

The priority for the Default Policy is always designated with the letter D, and the other active policies are prioritized with numbers 1, 2, and so on. Policy with priority 1 indicates the highest priority. When you assign an object to be a member of multiple object groups, and you assign a different policy to each object group, VCF Operations associates the highest ranking policy with that object.

When multiple policies apply to an object in VCF Operations, the policy with the highest priority is enforced on the object. The only exception is direct assignment: a lower-priority policy is enforced if it is assigned directly to the object.

**Table 1187: Configurable Policy Rule Elements**

| Policy Rule Elements | Thresholds, Settings, Definitions |
|---|---|
| Workload | Configure symptom thresholds for Workload. |
| Time Remaining | Configure thresholds for the Time Remaining. |
| Capacity Remaining | Configure thresholds for the Capacity Remaining. |
| Maintenance Schedule | Sets a time to perform maintenance tasks. |
| Attributes | An attribute is a collectible data component. You can activate or deactivate metric, property, and super metric attributes for collection, and set attributes as key performance indicators (KPIs). A KPI is the designation of an attribute that indicates that the attribute is important in your own environment. |
| Alert Definitions | Activate or deactivate combinations of symptoms and recommendations to identify a condition that classifies as a problem. |
| Symptom Definitions | Activate or deactivate test conditions on properties, metrics, or events. |

### How Upgrades Affect Your Policies

After you upgrade VCF Operations from a previous version, you might find newly added or updated default settings of policies such as, new alerts and symptoms. Hence, you must analyze the settings and modify these settings to optimize them for your current environment. If you apply the policies used with a previous version of VCF Operations, the manually modified policy settings remain unaltered.

## Policy Decisions and Objectives

Implementing policy decisions in VCF Operations is typically the responsibility of the Infrastructure Administrator or the Virtual Infrastructure Administrator, but users who have privileges can also create and modify policies.

You must be aware of the policies established to analyze and monitor the resources in your IT infrastructure.

- If you are a Network Operations engineer, you must understand how policies affect the data that VCF Operations reports on objects, and which policies assigned to objects report alerts and issues.
- If you are the person whose role is to recommend an initial setup for policies, you typically edit and configure the policies in VCF Operations.
- If your primary role is to assess problems that occur in your environment, but you do not have the responsibility to change the policies, you must still understand how the policies applied to objects affect the data that appears in VCF Operations. For example, you might need to know which policies apply to objects that are associated with particular alerts.
- If you are a typical application user who receives reports from VCF Operations, you must have a high-level understanding of the operational policies so that you can understand the reported data values.

# Policy Definitions

The **Policy Definition** page displays the base settings, default policy, and other best practice policies that VCF Operations includes. You can use the **Policy Definition** page to create your own policies. The **Policy Definition** page includes all the configurable settings for the policy elements, such as workload, capacity and time remaining, and so on.

## How Policy Definitions Work

Use the options in **Policy Definition** page to create your own policy from an existing policy, or to override the settings from an existing policy so that you can apply the new settings to groups of objects. You can also import or export a policy and reorder the policies.

Select a policy to display its details in the right pane. The right pane displays a high-level overview of all the details and options for that policy where these details are categorized in tabs. Expand each category to view all the related details.

When you add or edit a policy, you access the policy workspace where you select the base policies and override the settings for metrics and properties, alerts and symptoms, capacity, compliance, workload automation, and groups and objects. In this workspace, you can also apply the policy to objects and object groups. To update the policy associated with an object or object group, the role assigned to your user account must have the Manage Association permission activated for policy management.

## Where You Manage the Policy Definitions

To manage policy definitions, In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. A list of policies available to use for your environment are displayed.

**Table 1188: Policy Definition Options**

| Option | Description |
|---|---|
| ADD | Create a policy from an existing policy. |
| Horizontal Ellipsis > <Option> | • Edit. Customize the policy so that you can override settings for VCF Operations to analyze and report data about the associated objects.<br>• Delete. Remove a policy from the list.<br>• Set Default Policy. You can set any policy to be the default policy, which applies the settings in that policy to all objects that do not have a policy applied. When you set a policy to be the default policy, the priority is set to D, which gives that policy the highest priority.<br>• Export. Downloads the policy.<br>• Import. Allows you to import policies. To import:<br>– Click the **Import** option from the horizontal ellipsis.<br>– Click **Browse** and select the file to import.<br>– Select if you want to Overwrite or Skip the file in case of a conflict.<br>– Click **Import** to import the policy, and click **Done**.<br>**Note:**<br>To import or export a policy, the role assigned to your user account must have the Import or Export permissions activated for policy management.<br>• Reorder Policies. Change the priority of the active policies. |
| Filters | Limits the list based on the text you type.<br>You can also filter by:<br>• Name<br>• Description<br>• Modified By |

| Option | Description |
|---|---|
| Policies data grid | VCF Operations displays the high-level details for the policies.<br>• Name. Name of the policy as it appears in the Add or Edit Policy workspace, and in areas where the policy applies to objects, such as in Custom Groups.<br>• Status: Indicates whether the policy is active or inactive.<br>• Priority: Indicates the priority of the policy, if set.<br>• Description. Meaningful description of the policy, such as which policy is inherited, and any specific information users need to understand the relationship of the policy to one or more groups of objects.<br>• Last Modified. Date and time that the policy was last modified.<br>• Modified by: Displays the user who last modified the policy.<br>To view the data grid with the list of policies, click **Policy Definition** at the top of the page. |
| Policies data grid > Right Pane | The right pane displays the name and description of the policy from which the settings are inherited, the policy priority, and the option to edit the policy. From the right pane, you can view the complete group of settings that include both customized settings and the settings inherited from the base policies selected when the policy was created.<br>**Note:**<br>The right pane is only displayed after you select a policy from the grid view.<br>• Metrics and Properties: Displays all the attribute types included in the policy. Attribute type includes, metrics properties, and super metrics.<br>• Alerts and Symptoms: Displays all the alert and symptom definitions included in the policy. The Alert Definitions tabs display an overview of the alert definition, criticality, symptom, and state. The Symptoms Definitions tab displays an overview of the symptom name, criticality, and the metric name.<br>• Capacity: Displays an overview of all the thresholds of the objects included in the policy.<br>• Maintenance Schedule: Displays maintenance schedule elements that are defined locally in the policy. You can view and override the policy Maintenance Schedule analysis setting.<br>• Compliance: Displays the compliance thresholds inherited from the base policy or set while creating the policy.<br>• Workload Automation: Displays the details of the workload optimized in your environment per your definition.<br>• VC Pricing: Displays vCenter pricing details. You can add and assign new pricing cards to a vCenter instance and clusters in VCF Operations.<br>• Configuration Management Templates: Displays the vCenter or cluster configuration management templates. If you have not assigned your vCenter or cluster configuration templates to policies at the time of template creation, you can do so after the template creation process.<br>• Groups and Objects: Displays the object or object groups associated with the selected policy and the names of the objects in your environment, their object types, and associated adapters. When a parent group exists for an object, it is shown here. |

## Operational Policies

Determine how to have VCF Operations monitor your objects, and how to notify you about problems that occur with those objects.

VCF Operations Administrators assign policies to objects or object groups and applications to support Service Level Agreements (SLAs) and business priorities. When you use policies with objects or object groups, you ensure that the rules defined in the policies are quickly put into effect for the objects in your environment.

With policies, you can:

- Activate and deactivate alerts.
- Control data collections by persisting or not persisting metrics on the objects in your environment.
- Configure the product analytics and thresholds.
- Monitor objects and applications at different service levels.

- Prioritize policies so that the most important rules override the defaults.
- Understand the rules that affect the analytics.
- Understand which policies apply to objects or object groups.

VCF Operations includes a library of built-in active policies that are already defined for your use. VCF Operations applies these policies in priority order.

When multiple policies apply to an object in VCF Operations, the policy with the highest priority is enforced on the object. The only exception is direct assignment: a lower-priority policy is enforced if it is assigned directly to the object.

When you apply a policy to an object or an object group, VCF Operations collects data from the objects based on the thresholds, metrics, super metrics, attributes, properties, alert definitions, and problem definitions that are activated in the policy.

The following examples of policies might exist for a typical IT environment.

- Maintenance: Optimized for ongoing monitoring, with no thresholds or alerts.
- Critical Production: Production environment ready, optimized for performance with sensitive alerting.
- Important Production: Production environment ready, optimized for performance with medium alerting.
- Batch Workloads: Optimized to process jobs.
- Test, Staging, and QA: Less critical settings, fewer alerts.
- Development: Less critical settings, no alerts.
- Low Priority: Ensures efficient use of resources.
- Default Policy: Default system settings.

## Types of Policies

There are three types of policies such as default policies, custom policies, and policies that are offered with VCF Operations.

### Custom Policies

You can customize the default policy and base policies included with VCF Operations for your own environment. You can then apply your custom policy to an individual object or groups of objects, such as the objects in a cluster, or virtual machines and hosts, or to a group that you create to include unique objects and specific criteria.

You must be familiar with the policies so that you can understand the data that appears in the user interface, because policies drive the results that appear in the VCF Operations dashboards, views, and reports.

To determine how to customize operational policies and apply them to your environment, you must plan ahead. For example:

- Must you track CPU allocation? If you overallocate CPU, what percentage must you apply to your production and test objects?
- Will you overallocate memory or storage? If you use High Availability, what buffers must you use?
- How do you classify your logically defined workloads, such as production clusters, test or development clusters, and clusters used for batch workloads? Or, do you include all clusters in a single workload?
- How do you capture peak use times or spikes in system activity? In some cases, you might need to reduce alerts so that they are meaningful when you apply policies.

When you have privileges applied to your user account through the roles assigned, you can create and modify policies, and apply them to objects. For example:

- Create a policy from an existing base policy, inherit the base policy settings, then override specific settings to analyze and monitor your objects.
- Use policies to analyze and monitor vCenter objects and non- vCenter objects.
- Set custom thresholds for capacity settings on all object types to have VCF Operations report on workload, and so on.
- Activate specific attributes for collection, including metrics, properties, and super metrics.
- Activate or deactivate alert definitions and symptom definitions in your custom policy settings.
- Apply the custom policy to an individual object or groups of objects.

When you use an existing policy to create a custom policy, you override the policy settings to meet your own needs. You set the allocation and demand, the overcommit ratios for CPU and memory, and the thresholds for capacity risk and buffers. To allocate and configure what your environment is actually using, you use the allocation model and the demand model together. Depending on the type of environment you monitor, such as a production environment versus a test or development environment, whether you over allocate at all and by how much depends on the workloads and environment to which the policy applies. You might be more conservative with the level of allocation in your test environment and less conservative in your production environment.

When you establish the priority for your policies, VCF Operations applies the configured settings in the policies according to the policy rank order to analyze and report on your objects. When you assign an object to be a member of multiple object groups, and you assign a different policy to each object group, VCF Operations associates the highest ranking policy with that object.

Your policies are unique to your environment. Because policies direct VCF Operations to monitor the objects in your environment, they are read-only and do not alter the state of your objects. For this reason, you can override the policy settings to fine-tune them until VCF Operations displays the results that are meaningful and that affect for your environment. For example, you can adjust the capacity buffer settings in your policy, and then view the data that appears in the dashboards to see the effect of the policy settings.

## Default Policy in VCF Operations

The default policy is a set of rules that applies to most of your objects.

The Default policy is marked with the letter D in the Priority column and can apply to any number of objects.

All the Default policies appear in the Default Policy group in the policies library, even if that policy is not associated with an object group. When an object group does not have a policy applied, VCF Operations associates the Default policy with that group.

A policy can inherit the Default policy settings, and those settings can apply to various objects under several conditions.

The policy that is set to Default always takes the lowest priority. If you attempt to set two policies as the Default policy, the first policy that you set to Default is initially set to the lowest priority. When you set the second policy to Default, that policy then takes the lowest priority, and the earlier policy that you set to Default is set to the second lowest priority.

You can use the Default policy as the base policy to create your own custom policy. You modify the default policy settings to create a policy that meets your analysis and monitoring needs. When you start with the Default policy, your new policy inherits all the settings from the Default base policy. You can then customize your new policy and override these settings.

The data adapters and solutions installed in VCF Operations provide a collective group of base settings that apply to all objects. In the policy navigation tree in the policies library, these settings are called Base Settings. The Default policy inherits all the base settings by default.

## Policies Provided with VCF Operations

VCF Operations includes sets of policies that you can use to monitor your environment, or as the starting point to create your own policies.

Verify that you are familiar with the policies provided with VCF Operations so that you can use them in your own environment, and to include settings in new policies that you create.

### Where You Find the Policies Provided with VCF Operations Policies

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile to see the policies provided with VCF Operations.

### Policies That VCF Operations Includes

All policies exist under the Base Settings, because the data adapters and solutions installed in your VCF Operations instance provide a collective group of base settings that apply to all objects. In the policies library, these settings are called Base Settings.

The Base Settings policy is the umbrella policy for all other policies, and appears at the top of the policy list in the policies library. All the other policies reside under the Base Settings, because the data adapters and solutions installed in your VCF Operations instance provide a collective group of base settings that apply to all objects.

The configuration based policy set includes policies provided with VCF Operations that you use for specific settings on objects to report on your objects. This set includes several types of policies:

- Efficiency alerts policies for infrastructure objects and virtual machines
- Health alerts policies for infrastructure objects
- Overcommit policies for CPU and Memory
- Risk alerts policies for infrastructure objects and virtual machines

The Default Policy includes a set of rules that applies to most of your objects.

## Using the Policy Workspace to Create and Modify Operational Policies

You can use the workflow in the policy workspace to create local policies quickly, and update the settings in existing policies. Select a base policy to use as the source for your local policy settings, and modify the thresholds and settings used for analysis and collection of data from objects or object groups in your environment. A policy that has no local settings defined inherits the settings from its base policy to apply to the associated objects or object groups.

Verify that objects or object groups exist for VCF Operations to analyze and collect data, and if they do not exist, create them. See Managing Custom Object Groups in VCF Operations.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.
2. Click **Add** to add a policy or you can select a policy and click **Edit Policy** to edit an existing policy.

   You can add and edit policies and remove certain policies. You can use the Base Settings policy or the Default Policy as the root policy for the settings in other policies that you create. You can set any policy to be the default policy.
3. In the Create Policies workspace, assign a name to the policy, and enter the description.

   Give the policy a meaningful name and description so that all users know the purpose of the policy.
4. From the **Inherit From** drop-down, select one or more policies to use as a baseline to define the settings for your new local policy.

   You can use any of the policies provided with VCF Operations as a baseline source for your new policy settings.
5. Click **Create Policy**.

   The Create Policies workspace provides the options to customize your policy.
6. Click **Metrics and Properties**. In this workspace, select the metric, property, or super metric attributes to include in your policy.

   VCF Operations collects data from the objects in your environment based on the metric, property, or super metric attributes that you include in the policy.

   a) Click **Save** and return to the create policies workspace.
7. Click **Alerts and Symptoms**. In this workspace, select the alert definitions and symptom definitions, and activate or deactivate them as required for your policy.

   VCF Operations identifies problems on objects in your environment and triggers alerts when conditions occur that qualify as problems.

a) Click **Save** and return to the create policies workspace.

8. Click **Capacity**. In this workspace, select and override the situational settings such as committed projects to calculate capacity, time remaining, and other detailed settings.
   a) Click **Save** and return to the create policies workspace.
9. Click **Maintenance Schedule**. In this workspace, select and override the policy Maintenance Schedule analysis setting.
   a) Click **Save** and return to the create policies workspace.
10. Click **Compliance**. In this workspace, set the compliance threshold required for your policy.
    a) Click **Save** and return to the create policies workspace.
11. Click **Workload Automation**. In this workspace, select the optimization settings required for your policy.

    Click the lock icon to unlock and configure the workload automation options specific for your policy. When you click the lock icon to lock the option, your policy inherits the parent policy settings.
    a) Click **Save** and return to the create policies workspace.
12. Click **VC Pricing**. In this workspace you can add and assign new pricing cards to vCenter and clusters in VCF Operations.

    Click the lock icon to unlock and configure the VC Pricing options specific for your policy. When you click the lock icon to lock the option, your policy inherits the parent policy settings.

    a) Click **Save** and return to the create policies workspace.
13. Click **Configuration Management Templates**. In this workspace, if you have not assigned your vCenter or cluster configuration templates to policies at the time of template creation, you can do so after the template creation process.
    a) Click **Save** and return to the create policies workspace.
14. Click **Groups and Objects**. In this workspace, select one or more groups and objects to which the policy applies.

    VCF Operations monitors the objects according to the settings in the policy that is applied to the object or the object group, triggers alerts when thresholds are violated, and reports the results in the dashboards, views, and reports. If you do not assign a policy to one or more objects or object groups, VCF Operations does not assign the settings in that policy to any objects, and the policy is not active. For an object or an object group that dos not have a policy assigned, VCF Operations associates the object group with the Default Policy.

    Filter the object types, and modify the settings for those object types so that VCF Operations collects and displays the data that you expect in the dashboards and views.
    a) Click **Save** and return to the create policies workspace.

After VCF Operations analyzes and collects data from the objects in your environment, review the data in the dashboards and views. If the data is not what you expected, edit your local policy to customize and override the settings until the dashboards display the data that you need.

## Policy Workspace in VCF Operations

The policy workspace allows you to quickly create and modify policies. To create a policy, you can inherit the settings from an existing policy, and you can modify the settings in existing policies if you have adequate permissions. After you create a policy, or edit an existing policy, you can apply the policy to one or more objects or object groups.

### How the Policy Workspace Works

Every policy includes a set of packages, and uses the defined problems, symptoms, metrics, and properties in those packages to apply to specific objects or object groups in your environment. You can view the details for the settings inherited from the base policy, and display specific settings for certain object types. You can override the settings of other policies, and include additional policy settings to apply to the object types.

Use the **Add** and **Edit** options to create policies and edit existing policies.

### Where You Create and Modify a Policy

To create and modify policies, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy, and then in the right pane, click **Edit Policy** to edit the policy. The policy workspace is where you select the base policies, and customize and override the settings for analysis, metrics, properties, alert definitions, and symptom definitions. In this workspace, you can apply the policy to objects or object groups.

To remove a policy from the list, select the policy, click the horizontal ellipse, and select **Delete**.

### Policy Workspace Options

The policy workspace includes a step-by-step workflow to create and edit a policy, and apply the policy to custom object groups.

## Getting Started Details

When you create a policy, you must give the policy a meaningful name and description so that users know the purpose of the policy.

### Where You Assign the Policy Name and Description

To add a name and description to a policy, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy, and then in the right pane, click **Edit Policy** to edit a policy. The name and description appear in the Create or Edit policy workspace. Click the pencil icon to edit the field

**Table 1189: Name and Description Options in the Create or Edit Policy Workspace**

| Option | Description |
|---|---|
| Name | Name of the policy as it appears in the Create or Edit Policy screens, and in areas where the policy applies to objects, such as Custom Groups. |
| Description | Meaningful description of the policy. For example, use the description to indicate which policy is inherited, and any specific information that users must understand the relationship of the policy to one or more groups of objects. |
| Inherit From | The base policy that is used as a starting point. All settings from the base policy will be inherited as default settings in your new policy. You can override these settings to customize the new policy.<br>Select a base policy to inherit the policy settings as a starting point for your new policy.<br>You cannot edit this setting after a policy is created. |

## Select the Inherited Policy Details

You can use any of the policies provided with VCF Operations as a baseline source for your policy settings when you create a policy.

In the policy content area, you can perform the following actions:

- View the packages and elements for the inherited policy and additional policies that you selected to override the settings.
- Compare the differences in settings highlighted between these policies.
- Display object types.

To create a policy, select a base policy to inherit your new custom policy inherits settings. To override some of the settings in the base policy according to the requirements for the service level agreement for your environment, you can select and apply a separate policy for a management pack solution. The override policy includes specific settings defined for the types of objects to override, either manually or that an adapter provides when it is integrated with VCF Operations. The settings in the override policy overwrite the settings in the base policy that you selected.

When you select and apply a policy to use to overwrite the settings that your policy inherits from the base policy, the policy that you select appears in the policy settings cards.

Click each card to display the inherited policy configuration, and your policy, and displays a preview of the selected policy settings. When you select one of the policy cards, you can view the number of activated and deactivated alert definitions, symptom definitions, metrics and properties, and the number of activated and deactivated changes.

When you select the Groups and Objects card, you select the objects to view so that you can see which policy elements apply to the object type. For example, when you select the StorageArray object type, the workspace displays the local packages for the policy and the object group types with the number of policy elements in each group.

You can preview the policy settings for all object types, only the object types that have settings changed locally, or settings for new object types that you add to the list, such as Storage Array storage devices.

#### Where You Select and Override Base Policies Settings

To select a base policy to use as a starting point for your own policy, and to select a policy to override one or more settings that your policy inherits from the base policy, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy. In the Create policies workspace, add a name and description for the policy and from the **Inherit From** drop-down, select the base policy. The policy configuration, objects, and preview appear in cards below this drop-down.

## Capacity Details

You can filter the object types, and modify the settings for those object types so that VCF Operations applies these settings. The data that you expect then appears in the dashboards and views.

#### How the Capacity Workspace Works

When you turn on and configure the Capacity settings for a policy, you can override the settings for the policy elements that VCF Operations uses to trigger alerts and display data. These types of settings include symptom thresholds based on alerts, situational settings such as committed projects to calculate capacity and time remaining, and other detailed settings.

Policies focus on objects and object groups. When you configure policy settings for your local policy, you must consider the object type and the results that you expect to see in the dashboards and views. If you do not change these settings, your local policy retains the settings that your policy inherited from the base policy that you selected.

#### Where You Set the Policy Capacity Settings

To set the capacity settings for your policy, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy.

In the right pane, click **Edit Policy** to edit a policy. In the <policy name> [Edit] workspace, click the **Capacity** card. The capacity settings for host systems, virtual machines, and other object types that you select appears in the workspace.

You can also edit the capacity settings while working on the objects under the **Inventory** > **Capacity** tab. In the **Capacity** tab under **Inventory**, click the **Foundation Policy** drop-down and select **Edit Capacity Setting**.

**Table 1190: Capacity Settings in the Create or Edit Policy Workspace**

| Option | Description |
|---|---|
| Risk Level Configurations | You can set the risk level for the time that is remaining when the forecasted total need of a metric reaches usable capacity. Click the lock icon to override the settings and change the thresholds for your policy.<br>The following are the risk level settings. Use the slider below the graphical display to change the risk level. You can move the slider between Aggressive and Conservative.<br>• Conservative. Use this option for production and mission-critical workloads. This tells the capacity engine to create projections using all peak values (regular or occasional) that have been identified in the historical demand. Use this option to include the upper range of the data. The projection will be based on the high utilization points. Select Conservative for VMs with utilization spikes.<br>• Aggressive. Use this option for non-critical workloads. |
| Business Hours Schedule | Configure business hours as per your time zone, for calculation of capacity analysis and projections. VCF Operations considers the business hours for all objects using the current policy. During non-business hours, VMs could be running other data center activities such as OS upgrades, virus scans, etc after working hours, and hence may not appear to be idle. When you mark business hours schedules, VCF Operations can analyze after hours metrics for inventory, compliance, troubleshooting and other purposes. The reclamation and right sizing analysis and recommendations are based on the business hours and ignore spikes after business hours. Since the business hours schedule are based on policies, different objects can have different business hours. The capacity charts will be based on business hours.<br>**Note:**<br>You can set business hours schedule for VMs and clusters only.<br>**Note:**<br>After you specify business hours, the capacity forecast for the object will be based on the business hours and not 24 hours.<br>Click the lock icon on the left of each element to override the settings and change the thresholds for your policy. |
| Filters | Select the object type by which you want to filter. You can filter by Object Types, Local Changes, and Unsaved Changes. |
| Capacity Settings | Select an object to view the policy elements and settings for the object type so that you can have VCF Operations analyze the object type.<br>You can view and modify the settings for the following policy elements:<br>• Storage consideration for capacity calculation.<br>**Note:**<br>This option is only available for the Cluster Compute Resource.<br>• Allocation Model<br>• Custom Profile<br>• Capacity Buffer<br>Click the lock icon on the left of each element to override the settings and change the thresholds for your policy. |

| Option | Description |
|---|---|
| Criticality Thresholds and Metrics | There are two tabs in this settings.<br>Click the lock icon on the left of each element to override the settings and change the thresholds for your policy.<br>**Criticality Thresholds Tab**: You can view and modify the threshold settings for the following policy elements:<br>• Time Remaining<br>• Capacity Remaining<br>• Workload<br>**Custom Metrics Tab**: In the custom metrics tab, you can configure VCF Operations to use custom metrics in all the capacity calculations. The metrics that you configure in this tab replaces the default metrics that the VCF Operations capacity engine uses. When defining the custom metrics, you can select the metrics shipped with VCF Operations, or select super metrics. Only metrics which have the same unit as the internal metric used by the capacity engine, or a metric which has no unit, are displayed.<br>**Note:**<br>Enabling custom metrics in the capacity calculations is an advanced configuration. Custom metrics alter the way VCF Operations calculates capacity across your environment. Use this setting only when needed.<br>You can view and modify the custom metrics settings for all non-allocation capacity models. For example, for a data center, you can set custom metrics settings for Total Capacity and Utilization for Memory, CPU and Demand. When you click the **Edit** icon beside the total Capacity and Utililization settings, a list of available metrics opens in the right pane. Double click a default metric or super metric from the list to select it. Click **RESET TO DEFAULT** to revert your changes. Changes that you make take effect after the next collection cycle. |

Click **Save** to save the changes.

The local changes made will appear under **Policy Definition** > **Default Policy** > **Capacity** section. You can also view the preview of changes in the Capacity card.

### Policy Workload Element

Workload is a measurement of the demand for resources on an object. You can turn on and configure the settings for the Workload element for the object types in your policy.

#### How the Workload Element Works

The Workload element determines how VCF Operations reports on the resources that the selected object group uses. The resources available to the object group depend on the amount of configured and usable resources.

- A specific amount of physical memory is a configured resource for a host system, and a specific number of CPUs is a configured resource for a virtual machine.
- The usable resource for an object or an object group is a subset of, or equal to, the configured amount.
- The configured and usable amount of a resource can vary depending on the type of resource and the amount of virtualization overhead required, such as the memory that an ESX host machine requires to run the host system. When accounting for overhead, the resources required for overhead are not considered to be usable, because of the reservations required for virtual machines or for the high availability buffer.

### Where You Override the Policy Workload Element

To view and override the policy workload capacity setting, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the <policy name> [Edit] workspace, click the **Capacity** card. The workload settings for the object type that you have selected appear in the workspace.

View the Workload policy element, and configure the settings for your policy.

If you do not configure the policy element, your policy inherits the settings from the selected base policy.

**Table 1191: Policy Workload Element Settings in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Lock icon | Allows you to override the policy element settings so that you can customize the policy to monitor the objects in your environment. |
| Workload | Allows you to set the number of collection cycles it takes to trigger or clear an alert. |

## Policy Time Remaining Element

The Time remaining element is a measure of the amount of time left before your objects run out of capacity.

### How the Time Remaining Element Works

The Time Remaining element determines how VCF Operations reports on the available time until capacity runs out for a specific object type group.

- The time remaining indicates the amount of time that remains before the object group consumes the capacity available. VCF Operations calculates the time remaining as the number of days remaining until all the capacity is consumed.
- To keep the Time Remaining more than the critical threshold setting or to keep it green, your objects must have more days of capacity available.

### Where You Override the Policy Time Remaining Element

To view and override the policy Time Remaining capacity setting, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the <policy name> [Edit] workspace, click the **Capacity** card. The time remaining settings for the object type that you have selected appear in the workspace.

View the Time Remaining policy element and configure the settings for your policy.

If you do not configure the policy element, your policy inherits the settings from the selected base policy.

**Table 1192: Policy Time Remaining Element Settings in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Lock icon | Allows you to override the policy element settings so that you can customize the policy to monitor the objects in your environment. |
| Time Remaining | Allows you to set the number of days until capacity is projected to run out based on your current consumption trend. |

## Policy Capacity Remaining Element

Capacity is a measurement of the amount of memory, CPU, and disk space for an object. You can turn on and configure the settings for the Capacity Remaining element for the object types in your policy.

### How the Capacity Remaining Element Works

The Capacity Remaining element determines how reports on the available capacity until resources run out for a specific object type group.

- The capacity remaining indicates the capability of your environment to accommodate workload.
- Usable capacity is a measurement of the percentage of capacity available, minus the capacity affected when you use high availability.

### Where You Override the Policy Capacity Remaining Element

To view and override the policy Capacity Remaining analysis setting, in the VCF Operations s navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the <policy name> [Edit] workspace, click the **Capacity** card. The capacity remaining settings for the object type that you have selected appears in the workspace.

View the Capacity Remaining policy element and configure the settings for your policy.

If you do not configure the policy element, your policy inherits the settings from the selected base policy.

**Table 1193: Policy Capacity Remaining Element Settings in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Lock icon | Allows you to override the policy element settings so that you can customize the policy to monitor the objects in your environment. |
| Capacity Remaining | Allows you to set the percentage at which the capacity remaining alerts must be triggered. |

## Policy Allocation Model Element

Allocation model defines how much CPU, memory, or disk space is allocated to objects in a datastore, cluster or datastore cluster. In the policy, you can turn on the Allocation Model element and configure the resource allocation for the objects.

### How the Allocation Model Element Works

The Allocation Model element determines how calculates capacity when you allocate a specific amount of CPU, memory, and disk space resource to datastores, clusters or datastore clusters. You can specify the allocation ratio for either one, or all of the resource containers of the cluster. Unlike the demand model, the allocation model is used for capacity calculations only when you turn it on in the policy.

The allocation model element also affects the reclaimable resources for memory and storage in Reclaim page. When you turn on the Allocation Model element in the policy, the tabular representation of the VMs and snapshots in the selected data center from which resources can be reclaimed displays reclaimable memory and disk space based on the overcommit values.

### Where You Override the Allocation Model Element

To view and override the policy workload analysis setting, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.

Click **Add** to add a policy or select the required policy, and then in the right pane, click **Edit Policy** to edit a policy. In the <policy name> [Edit] workspace, click the **Capacity** card.

The allocation model settings for the object type that you selected appear in the workspace.

Click the unlock icon next to Allocation Model to set the overcommit ratios.

| Option | Description |
|---|---|
| Set overcommit ratio, to enable Allocation Model | Allows you to set the overcommit ratio for CPU, memory, or disk space. Select the check box next to the resource container you want to edit and change the overcommit ratio value. |

**Policy Custom Profile Element**
The custom profile element lets you apply a custom profile which shows how many more of a specified object can fit in your environment depending on the available capacity and object configuration.

**Where You Define the Custom Profiles**

To define a custom profile, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Custom Profiles ton** tile. Click **Add** to define a new custom profile.

**Where You Select the Custom Profile Element**

To view and override the policy Custom Profile analysis setting, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the <policy name> [Edit] workspace, click the **Capacity** card. The custom profile element for the object types such as datastores, clusters and datastore clusters that you selected appear in the workspace. Click the lock icon to unlock the section and make changes.

**Policy Capacity Buffer Element**
The capacity buffer element lets you add buffer for capacity and cost calculation. For vCenter objects, you can add buffer to CPU, Memory, and Disk Space for the Demand and Allocation models. You can add capacity buffer to datastores, clusters and datastore clusters. The values that you define here affect the cluster cost calculation. The time remaining, capacity remaining, and recommended values are calculated based on the buffer. For WLP, capacity buffer is first considered and then the headroom that you have defined is considered.

**Where You Define the Capacity Buffer**
To view and override the policy Capacity Buffer analysis setting, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the <policy name> [Edit] workspace, click the **Capacity** card. The Capacity Buffer for the object type that you selected appears in the workspace. Click the lock icon to unlock the section and make changes.

**How the Capacity Buffer Element Works**

The Capacity Buffer element determines how much extra headroom you have and ensures that you have extra space for growth inside the cluster when required. The value of the usable capacity reduces by the buffer amount that you specify here. The default buffer value is zero. If you are upgrading from a previous version of VCF Operations, the buffer values are carried forward to the new version.

The capacity buffer value that you specify for the Allocation model is considered only if you have activated allocation model in the policy.

Starting from version 8.6, capacity buffer is depreciated from cluster compute resources. The overcommit ratio setting (from the allocation model) and buffer settings, if set for the datastore object, takes precedence for the disk space related to datastore cluster and cluster objects. If these settings are not set, then, from a cost calculation perspective, the settings of datastore cluster and cluster (if the settings are missing for the datastore cluster as well), are used. The allocation and buffer settings made on the cluster does not impact the underlying datastores (as they do not inherit these settings), and the same works vice-versa, settings made for datastores are not propagated to the cluster.

The following tables display the capacity buffer that you can define based on the vCenter Adapter object types:

| Object Type | Valid Models for Capacity Buffer |
|---|---|
| CPU | Demand<br>Allocation |
| Memory | Demand<br>Allocation |
| Disk Space | Demand<br>Allocation |

## Maintenance Schedule Details

You can set a time to perform maintenance tasks for each policy.

### Where You Override the Policy Maintenance Schedule Element

To view and override the policy Maintenance Schedule analysis setting, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policies workspace, click **Maintenance Schedule**.

If you do not configure the policy element, your policy inherits the settings from the selected base policy.

**Table 1194: Policy Maintenance Schedule Element Settings in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Select Object Type | Select the object type. |
| Filters | You can filter by Local Changes and Unsaved Changes. Select **Yes** or **No** from the drop-down and click **Apply** to apply the filters. |
| Lock icon | Allows you to override the policy element settings so that you can customize the policy to monitor the objects in your environment. |
| Maintenance Schedule | Sets a time to perform maintenance tasks. During maintenance, VCF Operations does not calculate analytics. |

## Compliance Details

Compliance is a measurement that ensures that the objects in your environment meet industrial, governmental, regulatory, or internal standards. You can unlock and configure the settings for the compliance for the object types in your policy.

### Where You Override the Policy Compliance

To view and override the policy compliance setting, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policy workspace, click **Compliance**

View the compliance thresholds and configure the settings for your policy.

If you do not configure the policy element, your policy inherits the settings from the selected base policy.

**Table 1195: Compliance Settings in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Lock icon | Allows you to override the policy element settings so that you can customize the policy to monitor the objects in your environment. |
| Compliance | Allows you to set the compliance score threshold based on the number of violations against those standards. |

## Workload Automation Details

You can set the workload automation options for your policy, so that VCF Operations can optimize the workload in your environment as per your definition.

### How the Workload Automation Workspace Works

You click the lock icon to unlock and configure the workload automation options specific for your policy. When you click the lock icon to lock the option, your policy inherits the parent policy settings.

### Where You Set the Policy Workload Automation

Access this screen through the Policies pages:

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.
2. Select a policy that you want to modify. Ideally, this should be an active policy. Or, click the **ADD** button to add a new policy.
3. Select the **Workload Automation** card to review the changes, or click **EDIT POLICY** to make changes.

**Table 1196: Workload Automation in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Workload Optimization | Select a goal for workload optimization.<br>Select **Balance** when workload performance is your first goal. This approach proactively moves workloads so that the resource utilization is balanced, leading to maximum headroom for all resources.<br>Select **Moderate** when you want to minimize the workload contention.<br>Select **Consolidate** to proactively minimize the number of clusters used by workloads. You might be able to repurpose resources that are freed up. This approach is good for cost optimization, while making sure that performance goals are met. This approach might reduce licensing and power costs. |
| Cluster Headroom | Headroom establishes a required capacity buffer, for example, 20 percent. It provides you with an extra level of control and ensures that you have extra space for growth inside the cluster when required. Defining a large headroom setting limits the systems opportunities for optimization.<br>**Note:**<br>vSphere HA overhead is already included in useable capacity and this setting does not impact the HA overhead. |

| Option | Description |
|---|---|
| Change Datastore | Click the lock icon to select one of the following options:<br>• Do not allow Storage vMotion.<br>• Allow Storage vMotion. This is selected by default.<br>Using this option, you can select what type of virtual machines VCF Operations moves first to address workload.<br>• Storage Stress for Eviction<br>Select the checkbox to include the storage stress in the eviction criteria. In previous versions, cluster stress levels were determined solely by CPU and memory usage, meaning eviction decisions were not triggered by storage constraints. Starting with version 9.1, storage utilization contributes to the overall cluster stress calculation. Eviction decisions can be initiated when a cluster's storage capacity is constrained. |
| Target Network Policy Setting for WLP | Click the lock icon to select the following option:<br>• Generate a Target Network mapping<br>When you select this checkbox, the Workload Placement algorithm in will automatically choose compatible target network, while making the decision to move the VM for the optimization. For choosing compatible network WLP engine will consider the segment path and logical switch UUID of the Distributed Port Group.<br>Workload Optimization Across networks is supported when the optimization candidate clusters are assigned with different port groups (configured with NSX). These port groups configured via NSX have same segmentID and Logical Switch UUID. To enable this ability, check the respective setting in Workload Automation policy settings.<br>**Note:**<br>Segment ID and logical switch UUID properties are published on the VC port groups by NSX. So Worload Placement cannot provide a target network if it is not a NSX configuration and those properties are missing.<br>This setting is not selected by default. |

## Configuring vCenter Pricing Details

You can add and assign new pricing cards to vCenter and Clusters in VCF Operations. The pricing card can be cost-based or rate-based, you can customize the cost-based pricing card and rate-based pricing card as per your requirement. After configuring the pricing card, you can assign it to one more vCenter or Clusters based on your pricing strategy.

If you want to copy the vCenter pricing settings from the policy currently being edited to another policy, click **Copy local changes to other policy** and select the policy to which you want to copy the settings. The copied pricing configuration will override any existing local pricing configuration, in the target policy.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.
2. Select the required policy or click **Add** to add a new policy.
3. In the right pane, click **Edit Policy**.
4. In the <policy name> [Edit] workspace, click the **VC Pricing** card.
5. Click the Lock icon to override parent policy settings.
6. Select if you want to activate or deactivate the pricing engine.
7. Configure **Basic Charges**: Click the Lock icon to edit the parent policy settings. Pricing can be performed either on a cost basis or independent of it by specifying rate cards. The factor entered here is multiplied by the cost calculated as a derivative of cost drivers.
    1. Based on Cost/Based on Rate: Select if you want to pricing card to be cost-based or rate-based.
       The following options appear if you select the **Based on Cost** option:
        - CPU Cost: Enter a valid CPU cost factor.
        - Memory Cost: Enter a valid memory cost factor.
        - Storage Cost: Enter a valid storage cost factor.

- Additional Cost: Enter a valid additional cost factor.

The following options appear if you select the **Based on Rate** option:

- CPU Rate: Enter the CPU Rate per vCPU, the charging period, and how to charge for the resources.
- Memory Rate: Enter the memory rate per GB, the charging period, and how to charge for the resources.
- Storage Rate: Enter the storage rate per GB, the charging period, and how to charge for the resources.

8. Configure **Guest OS Rate**: Click **Guest OS Rate** in the left pane and then click the Lock icon to edit the parent policy settings. These are additional charges that have to be included based on the operating system running on the virtual machine. The name of the operating system should match exactly as discovered by VMware Tools.
   1. Click **Create Guest OS Rate** and enter the following details:
      – Guest OS Name: Enter a guest OS name.
      – Charge Period: The Charge Period indicates the frequency of charging.
      – Base Rate: Enter a base rate.

      The guest OS rates that you add appear in the table below. To edit or delete the entries, click the vertical ellipses and select the desired option.
9. **Tags**: Click **Tags** in the left pane and then click the Lock icon to edit the parent policy settings. Tag-based charges can be used to charge for value-added services such as antivirus database disaster recovery and other applications. These applications are to be represented as vCenter tags on the VMs for these charges to work.
   1. Recurring Charges: Recurring charges represent repeating charges such as monthly license fees for antivirus software. Click **Add Recurring Tag** and enter the following details:
      – Tag Category: Enter a tag key.
      – Tag Value: Enter a tag value.
      – Base Rate: Enter a base rate.
      – Charge Period: The Charge Period indicates the frequency of charging.
      – Charge Based on Power State: This decides whether the charge should be applied based on the power state of the VM.

      The tags that you add appear in the table below. To edit or delete the entries, click the vertical ellipses and select the desired option.
   2. One Time Tag: Tag-based one-time charges can be used to represent incidental charges such as charges for addressing a support ticket or charges for applying an operating systems patch. Click **Add One Time Tag** and enter the following details:
      – Tag Category: Enter a tag key.
      – Tag Value: Enter a tag value.
      – Base Rate: Enter a base rate.

      The tags that you add appear in the table below. To edit or delete the entries, click the vertical ellipses and select the desired option.
   3. Rate Factor Tag: Rate factors are multiplication factors applied to already calculated charges. For example, to add a 50% premium on storage, set a rate factor of 1.5 to storage charge. Click **Rate Factor Tag** and enter the following details:
      – Tag Category: Enter a tag key.
      – Tag Value: Enter a tag value.
      – Charge Applies To: Select what the charge applies to.
      – Rate Factor: Enter a valid number. For example, if you want to increase the price of CPU which has a tag 'Tag1-Value1' by 20% then select `CPU Charge` from the **Charge Applies To** drop-down list and enter `1.2` in **Rate Factor**.

      The tags that you add appear in the table below. To edit or delete the entries, click the vertical ellipses and select the desired option.
10. Configure **Overall Charges**: Click **Overall Charges** in the left pane and then click the Lock icon to edit the parent policy settings. Overall Charges are flat charges that are applied to VMs that match this policy.
    1. VM Setup Charges: Enter a valid setup fee. This is to charge for the setup of the VMs.
    2. Recurring Charges: Enter a valid number.

3. Charge Period: The Charge Period indicates the frequency of charging.

You can assign policies to the required Organization/Organization VDC under **Operate** > **Administration** > **Configurations**, and then click the **Policy Assignment** tile. For details, see Assigning Policies.

## Metrics and Properties Details

You can select the attribute type to include in your policy so that VCF Operations can collect data from the objects in your environment. Attribute types include metrics, properties, and super metrics. You activate or deactivate each metric, and determine whether to inherit the metrics from base policies that you selected in the workspace.

### How the Collect Metrics and Properties Workspace Works

When you create or customize a policy, you can override the base policy settings to have VCF Operations collect the data that you intend to use to generate alerts, and report the results in the dashboards.

To define the metric and super metric symptoms, metric event symptoms, and property symptoms, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitions** tile.

### Where You Override the Policy Attributes

To override the attributes and properties settings for your policy, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policy workspace, click **Metrics and Properties**. The attributes and properties settings for the selected object types appear in the workspace.

You can also edit the metrics and properties while working on the objects under the **Inventory** > **Metrics** tab. In the **Metrics** tab under **Inventory**, click the **Foundation Policy** drop-down and select **Edit Metrics Collection**.

**Table 1197: Metrics and Properties Options**

| Option | Description |
|---|---|
| Actions | Select one or more attributes and select activate, deactivate, or inherit to change the state and KPI for this policy. |
| Filter options | Deselect the options in the **Attribute Type**, **State**, **KPI**, and **DT** drop-down menus, to narrow the list of attributes.<br>• <br>Activated. Indicates that an attribute will be calculated.<br>• <br>Activated (Force). Indicates state change due to a dependency.<br>• <br>Deactivated. Indicates that an attribute will not be calculated.<br>• <br>Inherited. Indicates that the state of this attribute is inherited from the base policy and will be calculated.<br>• <br>Inherited. Indicates that the state of this attribute is inherited from the base policy and will not be calculated.<br>The KPI determines whether the metric, property, or super metric attribute is considered to be a key performance indicator (KPI) when VCF Operations reports the collected data in the dashboards. Filter the KPI states to display attributes with KPI activated, deactivated, or inherited for the policy. |
| Object Type | Filters the attributes list by object type. |
| Page Size | The number of attributes to list per page. |

| Option | Description |
|---|---|
| Attributes data grid | Display the attributes for a specific object type.<br>• Name. Identifies the name of the metric or property for the selected object type.<br>• Type. Distinguishes the type of attribute to be either a metric, property, or super metric.<br>• Adapter Type. Identifies the adapter used based on the object type selected, such as Storage Devices.<br>• Object Type. Identifies the type of object in your environment, such as StorageArray.<br>• State. Indicates whether the metric, property, or super metric is inherited from the base policy.<br>• KPI. Indicates whether the key performance indicator is inherited from the base policy. If a violation against a KPI occurs, VCF Operations generates an alert.<br>• DT. Indicates whether the dynamic threshold (DT) is inherited from the base policy. |

## Alert and Symptom Details

You can activate or deactivate alert and symptom definitions to have VCF Operations identify problems on objects in your environment and trigger alerts when conditions occur that qualify as problems. You can automate alerts.

### How the Alert and Symptom Definitions Workspace Works

VCF Operations collects data for objects and compares the collected data to the alert definitions and symptom definitions defined for that object type. Alert definitions include associated symptom definitions, which identify conditions on attributes, properties, metrics, and events.

You can configure your local policy to inherit alert definitions from the base policies that you select, or you can override the alert definitions and symptom definitions for your local policy.

Before you add or override the alert definitions and symptom definitions for a policy, familiarize yourself on the available alerts and symptoms.

- To view the available alert definitions, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Alert Definitions** tile.
- To view the available symptom definitions, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitions** tile. Symptom definitions are available for metrics, properties, messages, faults, smart early warnings, and external events.

A summary of the number of problem and symptoms that are activated and deactivated, and the difference in changes of the problem and symptoms as compared to the base policy, appear in the Analysis Settings pane of the policies workspace.

### Where You Override the Alert Definitions and Symptom Definitions

To override the alert definitions and symptom definitions for your policy, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policies workspace, click **Alerts and Symptoms**. The definitions appear in the workspace.

### Policy Alert Definitions and Symptom Definitions

You can override the alert definitions and symptom definitions for each policy.

#### Policy Alert Definitions

Each policy includes alert definitions. Each alert uses a combination of symptoms and recommendations to identify a condition that classifies as a problem, such as failures or high stress. You can activate or deactivate the alert definitions in your policy, and you can set actions to be automated when an alert triggers.

### How the Policy Alert Definitions Work

VCF Operations uses problems to trigger alerts. A problem manifests when a set of symptoms exists for an object, and requires you to take action on the problem. Alerts indicate problems in your environment. VCF Operations generates

alerts when the collected data for an object is compared to alert definitions for that object type and the defined symptoms are true. When an alert occurs, VCF Operations presents the triggering symptoms for you to take action.

Some of the alert definitions include predefined symptoms. When you include symptoms in an alert definition, and activate the alert, an alert is generated when the symptoms are true.

The Alert Definitions pane displays the name of the alert, the number of symptoms defined, the adapter, object types such as host or cluster, and whether the alert is activated as indicated by **Local**, deactivated as indicated by **not Local**, or inherited. Alerts are inherited with a green checkmark by default, which means that they are activated.

You can automate an alert definition in a policy when the highest priority recommendation for the alert has an associated action.

To view a specific set of alerts, you can select the badge type, criticality type, and the state of the alert to filter the view. For example, you can set the policy to send fault alerts for virtual machines.

### Where You Modify the Policy Alert Definitions

To modify the alerts associated with policies, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policies workspace, click **Alerts and Symptoms**. The alert definitions and symptom definitions for the selected object types appear in the workspace.

**Table 1198: Alert Definitions in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Object Type | Filters the alert definitions list by object type. |
| Filters | Limits the list based on the text you type.<br>You can also filter by:<br>• Name<br>• Criticality<br>• Impact<br>• State<br>• Automate<br>• Local Changes<br>• Unsaved Changes<br>Impact indicates the health, risk, and efficiency badges to which the alerts apply.<br>Criticality indicates the information, critical, immediate, warning, or automatic criticality types to which the alert definition applies.<br>Automate indicates the actions that are activated for automation when an alert triggers, or actions that are deactivated or inherited. Actions that are activated for automation might appear as inherited with a green checkmark, because policies can inherit settings from each other. For example, if the Automate setting in the base policy is set to **Local** with a green checkmark, other policies that inherit this setting will display the setting as inherited with a green checkmark.? |
| Actions | Select one or more alert definitions and select activate, deactivate, or inherit to change the state for this policy. |
| Page Size | The number of alert definitions to list per page. |

| Option | Description |
|---|---|
| Alert Definitions data grid | Displays information about the alert definitions for the object types. The full name for Alert definition and the criticality icon appear in a tooltip when you hover the mouse over the Alert Definition name.<br>• Alert Definition. Meaningful name for the alert definition.<br>• State. Alert definition state, either activated, deactivated, or inherited from the base policy.<br>• Automate. When the action is set to Local, the action is activated for automation when an alert triggers. Actions that are activated for automation might appear as inherited with a green checkmark, because policies can inherit settings from each other. For example, if the Automate setting in the base policy is set to **Local** with a green checkmark, other policies that inherit this setting will display the setting as inherited with a green checkmark.?<br>• Symptom. Number of symptoms defined for the alert.<br>• Criticality. Indicates the criticality of the alert.<br>• Actionable Recommendations. Only recommendations with actions in the first priority, as they are the only ones you can automate.<br>• Adapter. Data source type for which the alert is defined.<br>• Object Type. Type of object to which the alert applies. |

If you do not configure the package, the policy inherits the settings from the selected base policy.

### Activating the Deactivated Alerts

Several out-of-the-box alerts have been deactivated to enhance your alert experience and reduce alert noise in your environment. The alerts that are triggered for these deactivated alerts are auto-cancelled and as a result, you may experience a dip in the number of alerts triggered. However, you can still activate these alerts in specific policies.

The reason for deactivating these alerts is that there could be an overwhelming number of alerts when alerts are turned on for all objects, making it difficult to identify the ones that need immediate attention. It is recommended to exercise caution while activating the deactivated alerts for applicable policies.

Read the KB article, KB 91410 to know the list of deactivated alerts.

Perform the following steps to activate the deactivated alerts:

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.
2. Select the required policy and in the right pane, click **Edit Policy**, and then select the **Alerts and Symptoms** tile.
3. Go to Filters and enter the name of the deactivated alert, and click **Apply**. You can refer to the KB article, KB 91410 for the list of deactivated alerts.
4. Select **Activated** from the **State** drop-down list or click **Actions** > **State** > **Activated**.
5. Click **Save**.

   **Note:**
   You can also activate all the deactivated alerts at once. To do this, filter the alerts by **Deactivated** State, click on the **Select All** option, and from the **Actions** drop-down list, click **State** > **Activated**.

   **Note:**
   You can also activate the deactivated alerts by creating a separate policy, adding custom groups in that policy, and activating the alert definitions in the required policy. By doing this, the deactivated alerts are activated in the user-defined policy and will apply to the objects in the custom group. For more details on custom groups, see Managing Custom Object Groups in VCF Operations.

The deactivated alerts are now active.

**Policy Symptom Definitions**

Each policy includes a package of symptom definitions. Each symptom represents a distinct test condition on a property, metric, or event. You can activate or deactivate the symptom definitions in your policy.

## How the Policy Symptom Definitions Work

VCF Operations uses symptoms that are activated to generate alerts. When the symptoms used in an alert definition are true, and the alert is activated, an alert is generated.

When a symptom exists for an object, the problem exists and requires that you take action to solve it. When an alert occurs, VCF Operations presents the triggering symptoms, so that you can evaluate the object in your environment, and with recommendations for how to resolve the alert.

To assess objects for symptoms, you can include symptoms packages in your policy for metrics and super metrics, properties, message events, and faults. You can activate or deactivate the symptoms to determine the criteria that the policy uses to assess and evaluate the data collected from the objects to which the policy applies. You can also override the threshold, criticality, wait cycles, and cancel cycles.

The Symptoms pane displays the name of the symptom, the associated management pack adapter, object type, metric or property type, a definition of the trigger such as for CPU usage, the state of the symptom, and the trigger condition. To view a specific set of symptoms in the package, you can select the adapter type, object type, metric or property type, and the state of the symptom.

When a symptom is required by an alert, the state of the symptom is activated, but is dimmed so that you cannot modify it. The state of a required symptom includes an information icon that you can hover over to identify the alert that required this symptom.

## Where You Modify the Policy Symptom Definitions

To modify the policy package of symptoms, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile under the **Policies** section. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policies workspace, click **Alerts and Symptoms**. The alert definitions and symptom definitions for the selected object types appear in the workspace.

**Table 1199: Symptom Definitions in the Create or Edit Policies Workspace**

| Option | Description |
|---|---|
| Object Type | Select an object type to view the symptom definitions list by the selected object type. |
| Filters | Limits the list based on the text you type.<br>You can also filter by:<br>• Name<br>• Criticality<br>• Type<br>• State<br>• Local Changes<br>• Unsaved Changes |
| Actions | Select one or more symptom definitions and select activate, deactivate, or inherit to change the state for this policy. |
| Page Size | The number of symptom definitions to list per page. |

| Option | Description |
|---|---|
| Symptom Definitions data grid | Displays information about the symptom definitions for the object types. The full name for Symptom Definition appears in a tooltip when you hover the mouse over the Symptom Definition name.<br>• Symptom Definition. Symptom definition name as defined in the list of symptom definitions in the Content area. Click this name to view the details of the symptom.<br>• State. Symptom definition state, either activated, deactivated, or inherited from the base policy.<br>– <br>Activated. Indicates that a symptom definition will be included.<br>– <br>Activated (Force). Indicates state change due to a dependency.<br>– <br>Deactivated. Indicates that a symptom definition not be included.<br>– <br>Inherited. Indicates that the state of this symptom definition is inherited from the base policy and will be included.<br>– <br>Inherited. Indicates that the state of this symptom definition is inherited from the base policy and will not be included.<br>• Threshold. To change the threshold, you must set the State to **Activated**, set the condition to **Override**, and set the new threshold in the Override Symptom Definition Threshold dialog box.<br>• Type. Type of object to which the alert applies. Type determines whether symptom definitions that apply to HT and DT metrics, properties, events such as message, fault, and metric, and smart early warnings appear in the list.<br>• Criticality. Indicates the criticality.<br>• Adapter. Data source type for which the alert is defined.<br>• Object Type. Object type on which the symptom definition must be evaluated.<br>• Trigger. Static or dynamic threshold, based on the number of symptom definitions, the object type and metrics selected, the numeric value assigned to the symptom definition, the criticality of the symptom, and the number of wait and cancel cycles applied to the symptom definition.<br>• Condition. Activates action on the threshold. When set to Override, you can change the threshold. Otherwise set to default. |

If you do not configure the package, the policy inherits the settings from the selected base policy.

## Groups and Objects details

You can assign your local policy to one or more objects or groups of objects to have VCF Operations analyze those objects according to the settings in your policy. You can trigger alerts when the defined threshold levels are violated, and display the results in your dashboards, views, and reports.

### How the Groups and Objects Workspace Works

When you create a policy, or modify the settings in an existing policy, you apply the policy to one or more objects or groups of objects. VCF Operations uses the settings in the policy to analyze and collect data from the associated objects, and displays the data in dashboards, views, and reports.

### Where You Apply a Policy to Groups and Objects

To apply the policy to an object or groups of objects, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to

add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policies workspace, click **Groups and Objects**.

#### Groups and Objects Options

To apply the policy to an object or groups of objects, select the check box for the groups or objects in the workspace.

You can then view the groups and objects associated with the policy. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile. Click **Add** to add a policy or select the required policy. In the right pane, click **Edit Policy** to edit a policy. In the Create or Edit policies workspace, click **Groups and Objects**. Click the **Custom Groups** tab to apply the policy to one or more groups of objects. Click the **Objects** tabs to apply the policy to one or more objects.

For more information about how to create an object group, see the topic called **Custom Object Groups Workspace to Create a New Group**.

For more information about how to create a policy, see Policy Workspace in VCF Operations.

### Real-Time Metrics Details

To collect detailed performance data for effective troubleshooting, you can configure different tiers of metric collection within your monitoring policies. Essentials metrics are always enabled by default and cannot be turned off. If you disable higher-tier collections, like Standard, VCF Operations automatically falls back to collecting only the Essentials metrics. This section is displayed only if the real-time metrics component is deployed.

For more information on the different time-intervals of metric collection, see Real-time Data in the Workbench.

#### Enabling or Disabling 2-Second (ESX Top) Metric Collection

> **Note:**
>
> Before you can enable or disable 2-Second (ESX Top) metric collection, you must deploy and enable Real-Time metrics. For more information, see Deploy Real-Time Metrics.

To collect high-resolution data at a 2-second interval, you must activate the ESX Top category for host objects.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.
2. Click **Add** to add a policy or you can select a policy and click **Edit Policy** to edit an existing policy.
3. In the policy that you wish to add or edit, scroll down to the tile labeled **Real time metrics**.
4. By default, the **Select Object Type** may be set to **vCenter**. Click the dropdown menu and change it to **Host System**.
5. To Enable: Click the state dropdown menu next to **ESX Top** and select **Activated** in the State column.
6. To Disable: Click the state dropdown menu next to **ESX Top** and select **Deactivated**.
7. Click **SAVE** to apply your policy changes.

You can view 2-second granularity metrics for the selected host from the Troubleshooting Workbench when you select the ESX Top view. The ESX Top view is available for the Virtual Machine resource types. For more information, see Real-time Data in the Workbench.

#### Enabling or Disabling Standard Metric Collection

> **Note:**
>
> Before you can enable or disable Standard metric collection, you must deploy and enable Real-Time metrics. For more information, see Deploy Real-Time Metrics.
>
> **Note:**
>
> Standard metric collection can be enabled only on Large deployment types. For more information, see Start a New VCF Fleet or a New VCF Instance Deployment by Using the VCF Installer Deployment Wizard.

To collect standard metrics, you must activate the Standard category for vCenter objects. Standard metrics are collected at 20 seconds or more time interval.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definiton** tile.
2. Click **Add** to add a policy or you can select a policy and click **Edit Policy** to edit an existing policy.
3. In the policy that you wish to add or edit, scroll down to the tile labeled **Real time metrics**.
4. Ensure that the **Select Object Type** is set to **vCenter**.
5. To Enable: Click the state dropdown menu next to **Standard** and select **Activated** in the State column.
6. To Disable**:** Click the state dropdown menu next to **Standard** and select **Deactivated**. The metrics which are part of Standard profile are stopped, and they seamlessly move back to the default Essentials collection.
7. Click **SAVE** to apply your policy changes.

For more information on the objects and their time collection interval, download the XLS file here.

# Assigning Policies

The **Policy Assignment** workspace displays all the policies available in your environment.

### Where You Assign Policies

To create and modify policy assignments, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Assignments** tile.

### How the Policy Assignment Workspace Works

You can assign policies to your environment to activate controls, view, and manage your object assignment scope.

| Option | Description |
|---|---|
| Left Pane: Displays the list of policies available in your environment and provides different filters to understand policy distribution. | |
| Inactive/Active | You can filter policies by active or inactive status. A policy is considered to be active only when it is assigned to an object or a custom group. |
| Visualization Type | You can sort active policies based on different criteria.<br>• Fixed: Displays active policies with the sections of the policies fixed and equal to each other.<br>• By Assignments: Displays the policies based on the number of objects assigned.<br>• By Affected Objects: Displays policies based on the affected object count.<br>**Note:**<br>The sorting options are available only for the active policies. |
| Type Policy Name | Type the name of the policy in the search box to filter by policy name. |
| Policies | All the policies available in your environment are displayed in the left pane. Expand the policy card to view the priority, direct assignments, custom groups, affected objects, default assignment, and hierarchy of the policy.<br>**Note:**<br>The default assignments are displayed only for the default policy.<br>When you click on a policy, the objects and custom groups associated with the selected policy are displayed under **Assigned Objects** in the right pane. |

| Option | Description |
|---|---|
| Right Pane: Displays details of the selected policy and allows you to drag and drop objects or custom groups to the selected policy. | |
| Selected Policy | Displays the name of the selected policy. |
| All Objects | Displays all objects and custom groups available in your environment in the **Inventory** and **Custom Groups** tabs respectively.<br>To add new objects to a policy:<br>1. In the right pane, click **All Objects** > **Inventory**.<br>2. Select the objects you want to assign to the policy. You can also search for the objects by typing the object name in the search box.<br>3. Drag the items from the **Inventory** tab and drop them into the policy card on the left pane.<br>4. In the **Assign Objects** window, select one of the following options:<br>a. Only this object: Select this if you want to apply changes only to the selected objects.<br>b. Include child object: Select this if you want to apply changes to the child objects. You can define the depth of change by entering a number in the **Depth** field.<br>**Note:**<br>The maximum value for the Depth field is 10.<br>5. Click **Confirm**.<br>To add custom groups to a policy:<br>1. In the right pane, click **All Objects** > **Custom Groups**.<br>2. Select the custom groups you want to assign to the policy in the **Custom Groups** tab. You can also search for the custom groups by typing the custom group name in the search box.<br>3. Drag the items from the **Custom Groups** tab and drop them into the policy card on the left pane.<br>4. Click **Confirm**. |
| Assigned Objects | Displays the objects and custom groups assigned to the selected policy.<br>• Name: Displays the name of the object/custom group.<br>• Assignment Type: Displays the type of assignment.<br>• Depth: Displays the depth of the child objects that the policy affects. Click the Edit icon to change the depth.<br>• Action: Allows you to delete an object or custom group.<br>You can also drag objects/custom groups from **Assigned Objects** and drop them into the policy card of your choice. |

When multiple policies apply to an object in VCF Operations, the policy with the highest priority is enforced on the object. The only exception is direct assignment: a lower-priority policy is enforced if it is assigned directly to the object.

# Configuring Alerts and Using Actions

Alerts are a way to be watchful of anything that is new or an issue that could be potentially dangerous to your environment. Whenever there is a problem in the environment, the alerts are generated. You can also create new alert definitions so that the generated alerts inform you about the problems in the monitored environment. In VCF Operations , alerts and actions play key roles in monitoring the objects.

You may have several questions while working on alerts. Following are some of the key questions that will help you navigate through the alert documentation.

- Where can I find all my alerts?

- What are the different types of alerts?
- Where can I get more information about alerts?
- How do I create a new alert definition?
- How do I define new symptoms?
- How do I define recommendations for my alerts?
- How can I create notification rules for alerts?
- How do I add my Outbound Plugins?
- How do I create payload templates for my Outbound Plugins?
- How can I export or import Outbound Settings?
- How do I deactivate alerts?
- How do I group alerts?
- What is intelligent alert clustering and how does it help in alert noise reduction?

Actions allow you to make changes to the objects in your environment. When you grant a user access to actions in VCF Operations , that user can take the granted action on any object that VCF Operations manages. For details, see Actions in VCF Operations.

# Understanding Alerts in VCF Operations

This topic provides information on the different types of alerts in VCF Operations, how to access them, and how to view more information about these alerts.

### Types of Alerts

Alerts in VCF Operations are of three types.

| | |
|---|---|
| **Health Alerts** | The health alert list is all the generated alerts that are configured to indicate problems with your environment. You use the health alert list to evaluate, prioritize, and resolve the problems. |
| **Risk Alerts** | The risk alerts list is all the generated alerts that are configured to indicate risk in your environment. Address risk alerts in the near future, before the triggering symptoms that generated the alert negatively affect the health of your environment. |
| **Efficiency Alerts** | The efficiency alerts list is all the generated alerts that are configured to indicate problems with the efficient use of your monitored objects in your environment. Address efficiency alerts to reclaim wasted space or to improve the performance of objects in your environment. |

## Accessing Alerts VCF Operations

The **Alerts** or the **Administrative Alerts** page provides a list of alerts generated in VCF Operations. Use the alert list to determine the state of your environment and to begin resolving problems.

### Where You Find the All Alerts Page

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Alerts**.

### Where You Find the Administrative Alerts Page

As an admin, you can view the administrative alerts by clicking the warning icon next to the Alerts menu or in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Alerts**, and then click the **Administrative Alerts** tab. You can view the **Administrative Alerts** page, only if you are a global admin user or if you have administrative privileges assigned to you.

### How the Alerts and Administrative Alerts Pages Work

By default, only active alerts are initially listed, and the alerts are grouped by **Definition**. Review and manage the alerts in the list by selecting the check box next to it. You can select multiple rows in the list using Shift+click, Control+click, and then use the **Actions** button drop-down list to perform an action on the selected alerts(s).

To see the alert details, click the alert name. The alert details appear on the right, including the symptoms triggered by the alert. The system offers recommendations for addressing the alert and link to run the recommendation. A Run Action button may appear in the details. Hover over the button to learn what recommendation is performed if you click the button. Click the small box on the lower left of the alert list to include the **Suggested Fix** column in the data grid. You can filter by alerts that have the Run option activated and perform the recommended task to address the alert from the Alerts data grid.

Click the name of the object on which the alert was generated to see the object details, and access additional information relating to metrics and events.

If you migrated alerts from a previous version of VCF Operations, the alerts are listed with a cancelled status and alert details are not available.

### All Alerts and Administrative Alerts Options

The alert options include toolbar and data grid options. Use the toolbar options to sort the alert list and to cancel, suspend, or manage ownership. Use the data grid to view the alerts and alert details.

Select an alert from the list to activate the Actions menu:

**Table 1200: Actions Menu**

| Option | Description |
|---|---|
| Cancel Alert | Cancels the selected alerts. If you configure the alert list to display only active alerts, the canceled alert is removed from the list.<br>Cancel alerts when you do not need to address them. Canceling an alert does not cancel the underlying condition that generated it. Canceling alerts is effective if the alert is triggered by fault and event symptoms, because these symptoms are triggered again only if subsequent faults or events occur on the monitored objects. If the alert was generated based on metric or property symptoms, the alert is canceled only until the next collection and analysis cycle. If the violating values are still present, the alert is generated again. |
| Delete Canceled Alerts | Delete canceled (inactive) alerts by doing a group selection or by individually selecting alerts. The option is deactivated for active alerts. |
| Suspend | Suspend an alert for a specified number of minutes.<br>You suspend alerts when you are investigating an alert and do not want the alert to affect the health, risk, or efficiency of the object while you are working. If the problem persists after the elapsed time, the alert is reactivated and it will again affect the health, risk, or efficiency of the object.<br>The user who suspends the alert becomes the assigned owner. |
| Assign to | Assign the alert to a user. You can search for a specific username and click **Save** to assign the alert to the selected user. |
| Take Ownership | As the current user, you make yourself the owner of the alert. You can only take ownership of an alert, you cannot assign ownership. |
| Release Ownership | Alert is released from all ownership. |
| Go to Alert Definition | Switches to the Alert Definitions page, with the definition for the previously selected alert displayed. |

| Option | Description |
|---|---|
| Deactivate... | Provides two options to deactivate the alert:<br>**Note:**<br>To activate the Deactivate option, select **Definition** from the **Group By** drop-down list, and click on the name of the Alert Definition Group.<br>• Deactivate the alert in all policies: This deactivates the alert for all objects for all the policies.<br>• Deactivate alert in selected policies: This deactivates the alert for objects having the selected policy. |
| Open an external application | Actions you can run on the selected object.<br>For example, Open Virtual Machine in vSphere Client. |

**Table 1201: Group By Options**

| Option | Description |
|---|---|
| None | Alerts are not sorted into specific groupings. |
| Definition | Group alerts by definition, that is, group like alerts together. This is the default option. |
| Scope | Group alerts by scope. You can search for alerts within the selected scope. |
| Time | Group alerts by time triggered. You can also group by 1 hour, 4 hours, Today and Yesterday, days of current week, Last week and Older. |
| Criticality | Group alerts by criticality. Values are, from the least critical: Info/ Warning/Immediate/Critical. See also Criticality in the "All Alerts Data Grid Options" table, below. |
| Object Type | Group alerts by the type of object that triggered the alert. For example, group alerts on hosts together. |

**Table 1202: Quick Filters (Alert)**

Alist of fields that can be filtered on by clicking on the funnel icon in the filters bar.

| Quick Filters | Descriptions |
|---|---|
| Filtering options | Limit the list of alerts to those matching the filters you choose.<br>For example, you might have chosen the Time option in the Group By menu. Now you can choose Status -> Active in the Quick Filters menu, and the All Alerts/Administrative Alerts page displays only the active alerts, ordered by the time they were triggered. |
| Options (see also the Group By table for more filter definitions) | |
| Alert id | ID given for an alert. |
| Alert | Name of the alert definition that generated the alert. |
| Owner | Name of operator who owns the alert. |
| Impact | Health, risk, or efficiency indicates the impact category/area. |
| Alert Type | Types of alerts such as Storage, Network, Administrator, and so on helps you find specific alerts. |

| Quick Filters | Descriptions |
|---|---|
| Alert Subtype | Additional information about the type of alert that is triggered on a selected object. This helps you categorize the alerts in a detailed level other than Alert Type, so that you can assign certain types of alerts to specific system administrators. For example, Availability, Performance, Capacity, Compliance, and Configuration. |
| Status | Current state of the alert.<br>Possible values include Active or Canceled. |
| Criticality | The level of importance of the alert in your environment.<br>The level is based on the level assigned when the alert definition was created, or on the highest symptom criticality, if the assigned level was **Symptom Based**.<br>The possible values include:<br>• Critical<br>• Immediate<br>• Warning<br>• Information |
| Triggered On | Name of the object for which the alert was generated, and the object type, which appears in a tooltip when you hover the mouse over the object name.<br>Click the object name to view the object details tabs where you can begin to investigate any additional problems with the object. |
| Control State | State of user interaction with the alert. Possible values include:<br>• Open. The alert is available for action and has not been assigned to a user.<br>• Assigned. The alert is assigned to the user who is logged in when that user clicks **Take Ownership**.<br>• Suspended. The alert was suspended for a specified amount of time. The alert is temporarily excluded from affecting the health, risk, and efficiency of the object. This state is useful when a system administrator is working on a problem and does not want the alert to affect the health status of the object. |
| Object Type | Type of object on which the alert was generated. |
| Created On | Date and time when the alert was generated. |
| Updated On | Date and time when the alert was last modified.<br>An alert is updated whenever one of the following changes occurs:<br>• Another symptom in the alert definition is triggered.<br>• Triggering symptom that contributed to the alert is canceled. |
| Canceled On | Date and time when the alert canceled for one of the following reasons:<br>• Symptoms that triggered the alert are no longer active. Alert is canceled by the system.<br>• Symptoms that triggered the alert are canceled because the corresponding symptom definitions are deactivated in the policy that is applied to the object.<br>• Symptoms that triggered the alert are canceled because the corresponding symptom definitions were deleted.<br>• Alert definition for this alert is deactivated in the policy that is applied to the object.<br>• Alert definition is deleted.<br>• User canceled the alert. |

| Quick Filters | Descriptions |
|---|---|
| Action | Choose **Yes** to filter based on alerts that have the **Run** option activated. Choose **No** to filter based on alerts that have the **Run** option deactivated. |

The Alerts data grid provides the list of generated alerts used to resolve problems in your environment. An arrow in each column heading orders the list in ascending or descending order.

**Table 1203: Alerts and Administrative Alerts Data Grid**

| Option | Description |
|---|---|
| Criticality | Criticality is the level of importance of the alert in your environment. Color coded icon where the shape of the icon represents the type (Health, Risk, Efficiency), and the colour the criticality.<br>The level is based on the level assigned when the alert definition was created, or on the highest symptom criticality, if the assigned level was **Symptom Based**.<br>The possible values include:<br>• Critical<br>• Immediate<br>• Warning<br>• Information |
| Alert | Name of the alert definition that generated the alert.<br>Click the alert name to display the alert details to the right. |
| Triggered On | Name of the object for which the alert was generated, and the object type, which appears in a tooltip when you hover the mouse over the object name.<br>Click the object name to view the object details tabs where you can begin to investigate any additional problems with the object. |
| Created On | Date and time when the alert was generated. |
| Status | Current state of the alert. Values are Active or Inactive. |
| Alert Type | Describes the type of alert that triggered on the selected object, and helps you categorize the alerts so that you can assign certain types of alerts to specific system administrators. For example, Application, Virtualization/Hypervisor, Hardware, Storage, Network, Administrative, and Findings. |
| Alert Subtype | Describes additional information about the type of alert that triggered on the selected object, and helps you categorize the alerts to a more detailed level than Alert Type, so that you can assign certain types of alerts to specific system administrators. For example, Availability, Performance, Capacity, Compliance, and Configuration. |
| Importance | Displays the priority of the alert. The importance level of the alert is determined using a smart ranking algorithm. |
| Suggested Fix | Displays the recommendation to address the alert.<br>This column is not displayed by default. Click the small box on the lower left of the alert list to include the **Suggested Fix** column in the data grid. |
| Action | Click this button to perform the recommendation to address the alert.<br>This column is not displayed by default. Click the small box on the lower left of the alert list to include the **Action** column in the data grid. |

## Viewing Alert Information

When you click an alert from the alerts list, the alert information appears on the right. View the alert information to see the symptoms which triggered the alert, recommendations to fix the underlying issue, and troubleshoot the cause of the alert.

**Different ways to view Alert information**

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Alerts**.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**. Select a group, custom data center, application, or inventory object. Click the object and then the **Alerts** tab.
- In the VCF Operations navigation bar at the top, click the **Search** icon and locate the object of interest. Click the object and then the **Alerts** tab.

The alert description is hidden when you open the alert information. Click **View Description** to see the description of the alert. View the time stamp of when the alert started, and when it was updated, below the alert title.

**Alert Details Tab**

| Section | Description |
|---|---|
| Recommendations | View recommendations for the alert. Click **<** or **>** to cycle through the recommendations. To resolve the alert, click the **Run Action** button if it appears. |
| Other Recommendations | Collapse the section to view additional recommendations. See the links in the **Need More Information?** section to view additional metrics, events, or other details that appear as a link. |
| Alert Basis | |
| Active Only | This option is activated by default. When activated, all active symptoms/conditions that were met for the alert are displayed. When deactivated, all the symptoms/conditions of an alert are displayed. |
| Symptoms | View the symptoms that triggered the alert. Collapse each symptom to view additional information. |
| Conditions | View the conditions that triggered the alert. Collapse each condition to view additional information. |
| Notes | Enter your notes about the alert and click **Submit** to save. |
| Close | Click the X icon to close the alert details tab. |

**Related Alerts Tab**

The **Related Scope** displayed on the right, shows the objects that are one level above and one level below the object on which the alert was triggered. This topology is fixed. You cannot change the scope in the **Related Alerts** tab.

On the right, you can see the following:

- If the same alert was triggered on the object in the past 30 days. This helps you understand if this is a recurring problem or something new.
- If the same alert was triggered on other peers in the same environment, in the past 30 days. This helps you do a quick peer analysis to understand if others are impacted with the same problem.
- All the alerts triggered in the current topology. This helps you investigate if there are other alerts upstream or downstream in the environment which are impacting the health of the object.

**Potential Evidence Tab**

See the **Potential Evidence** tab for potential evidences around the problem, and to arrive at the root cause. This tab displays events, property changes, and anomalous metrics potentially relevant to the alert. The time range and the scope are fixed. To modify the scope or the time range and investigate further, click **Launch Workbench**. This runs the troubleshooting workbench.

The time range that is displayed in the potential evidence tab is two hours and thirty minutes before the alert was triggered. VCF Operations looks for potential evidences in this time range.

## Intelligent Alerts

Every enterprise could have multiple tools that monitor various aspects of their data center operations around the clock. This could cause an alert flooding situation where multiple alerts are generated by a single monitoring tool or multiple tools for the same problem. As a result, IT administrators must sift through thousands of alerts to filter out the noise and focus on key issues, thus, increasing the sheer volume of the alerts and posing an alert storm or alert noise resulting in teams being unable to identify the most critical alerts. Alert flooding happens because monitoring tools lack the intelligence to understand that all alerts depict the same problem.

Machine Learning (ML) helps automate the management of complex systems that contain thousands of objects like VMs, Hosts, and Datastores, through monitoring millions of metrics, huge volumes of logs, and application traces, to capture a high-resolution image of the entire stack.

VCF Operations through intelligent alert clustering helps eliminate business downtime that happens because of a lack of faster troubleshooting abilities and solving critical problems over multiple objects.

### Where You Find the Intelligent Alerts Tab

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Alerts**.

### How Intelligent Alert Clustering Works

Intelligent alerts, also known as alert clusters in VCF Operations, groups related alerts together based on their creation time and their topology distance. This approach provides a more organized and efficient method for troubleshooting, compared to dealing with individual alerts arising from the same underlying issue. Alerts clustering is done based on DBScan algorithm. DBScan (Density-Based Spatial Clustering of Applications with Noise) is an unsupervised clustering Machine Learning algorithm that attempts to group data points closely packed into artificial clusters. In the context of VCF Operations, DBScan has been tailored into a streaming algorithm with specific parameters configured such as minimum points is set to five, time difference is set to fifteen minutes, and topology distance is set to one, for considering only direct children and parents. Two main views, Intelligent alert lifetime and Objects topology, are provided for alert cluster troubleshooting.

The **Intelligent Alert** tab displays the list of alert clusters in the left pane. Click any alert cluster to view the details in the right pane.

| Option | Description |
|---|---|
| Filters | You can filter the alert clusters by their status. Select **Active** or **Inactive** from the **Status** drop-down list and click **Apply**. |
| Alert Cluster | The alert cluster card displays the following:<br>• **Status**: Displays if the status of the alert cluster is active or inactive.<br>• **Object**: Displays the name of the object to which the cluster is assigned.<br>• **Alert Chart**: Displays the number of alerts and objects along with the criticality of the alert. Hover over the graph to view the details.<br>• **Start time**: Displays the time when the first cluster that satisfies the clustering condition is identified.<br>• **End time**: Displays the time when the cluster no longer qualifies to be an alert cluster.<br>Click the alert cluster to view the details in the right pane. |
| Object | Name of the root object. |
| Start time/End time | The start time of the alert cluster is the time when the first cluster that satisfies the clustering condition is identified. The end time of the alert cluster is the time when the cluster no longer qualifies to be an alert cluster. |

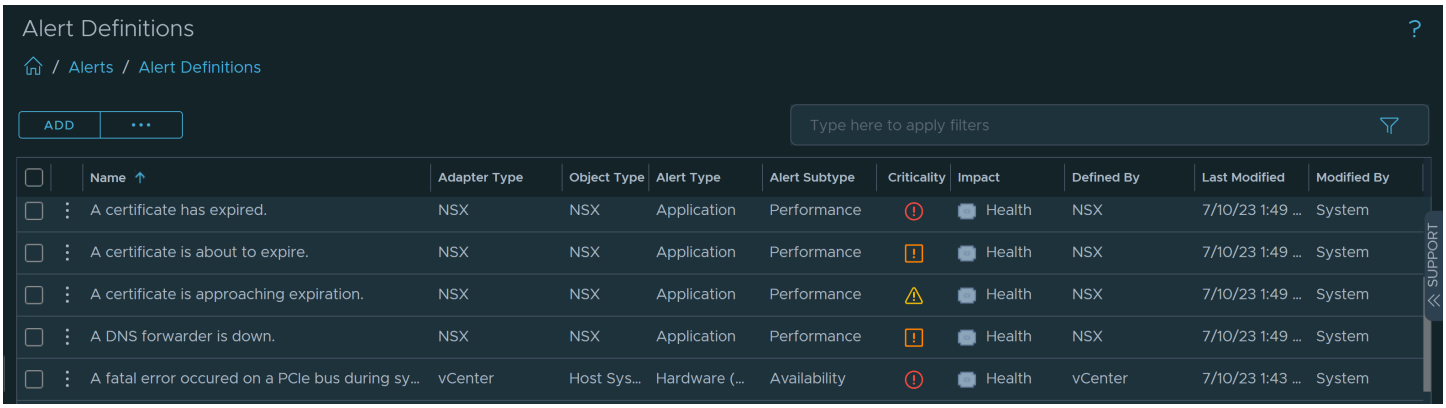
| Option | Description |
|---|---|
| Alerts/Objects | Select **Alerts** to view the graphical representation of alerts in a specific period.<br>Select **Objects** to view the object-relationship chart for an alert cluster. Hover over the object and click **Details** to open the Summary page of the object. |
| How it Started | Click **How it Started** to view the lifetime of an alert cluster. Each bubble displays alerts and objects, hover over the bubble to view more details. |
| Troubleshoot | Click this to launch the Troubleshooting workbench for further troubleshooting. |
| Graph Chart | The graph chart displays the number of alerts by time, for the selected alert cluster.<br>Click the chart legend to filter alerts by:<br>• Criticality<br>  – Critical<br>  – Immediate<br>  – Warning<br>  – Info<br>• Objects<br>Click the Calendar icon to view past alerts by selecting the **Range** or by selecting a date in the **From** and **To** fields. |
| Group By | You can group alerts by:<br>• Definition<br>• Scope<br>• Time<br>• Criticality<br>• Object Type |
| Filters | You can filter alerts by:<br>• Alert ID<br>• Alert name<br>• Owner<br>• Impact<br>• Alert Type<br>• Alert Subtype<br>• Status |

## Alert Definitions in VCF Operations

Alert definitions are a combination of symptoms and recommendations that you combine to identify problem areas in your environment and generate alerts on which you can act for those areas. You can then respond to the alerts with effective solutions that are provided in the recommendations.

## Where You Find Alert Definitions

To manage your alert definitions, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Alerts Definiton** tile under the **Alerts** section.



| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your alert definitions.<br>• Add. Add an alert definition.<br>Click the horizontal ellipsis to perform the following actions.<br>• Delete. Remove the selected definition.<br>• Export. Downloads the alert definition.<br>• Import. Allows you to import alert definitions. To import:<br>– Click the **Import** option from the horizontal ellipsis.<br>– Click **Browse** and select the file to import.<br>– Select if you want to Overwrite or Skip the file in case of a conflict.<br>– Click **Import** to import the alert definition, and click **Done**.<br>Click on the vertical ellipsis against an individual alert definition to perform the following actions.<br>• Edit. Modify the selected definition.<br>• Delete. Remove the selected definition.<br>• Clone. Create a copy of the selected definition so that you can customize it for your needs.<br>• Export. Downloads the alert definition. |
| Filters | Limits the list of alerts to those matching the filter you create.<br>You can also sort on the columns in the data grid. |
| **Data Grid Columns** | |
| Name | Name of the alert definition, which is also the name of the alert that appears when the symptoms are triggered. |
| Adapter Type | Adapter that manages the selected base object type. |
| Object Type | Base object type against which the alert is defined. |
| Alert Type | Metadata that is used to classify the alert when it is generated.<br>You define the value on the Alert Impact page of the workspace. |
| Alert Subtype | Subcategory of the alert type and is the metadata that is used to classify the alert when it is generated.<br>You define the value on the Alert Impact page of the workspace. |

| Option | Description |
|---|---|
| Criticality | Severity of the alert when it is generated. The criticality includes the following possible values:<br>• Symptom. Alert is configured to display symptom based criticality.<br>• Critical<br>• Immediate<br>• Warning<br>• Info |
| Impact | Alert is configured to affect the Health, Risk, or Efficiency badge. |
| Defined by | Indicates who added the alert definition. The alert can be added by an adapter, a user, or the VCF Operations system. |
| Last Modified | Displays the date on which the alert was last modified. |
| Modified By | Displays the user who last modified the alert. |

Predefined alerts are provided in VCF Operations as part of your configured adapters. Use Alert Definitions to manage your VCF Operations alert library, and to add or modify the definitions.

**Modifying Alert Definitions**

If you modify the alert impact type of an alert definition, any alerts that are already generated will have the previous impact level. Any new alerts will be at the new impact level. If you want to reset all the generated alerts to the new level, cancel the old alerts. If they are generated after cancellation, they will have the new impact level.

**Symptoms in Alert Definitions**

Symptom definitions evaluate conditions in your environment that, if the conditions become true, trigger a symptom and can result in a generated alert. You can add symptom definitions that are based on metrics or super metrics, properties, message events, fault events, or metric events. You can create a symptom definition as you create an alert definition or as an individual item in the appropriate symptom definition list.

When you add a symptom definition to an alert definition, it becomes a part of a symptom set. A symptom set is the combination of the defined symptom with the argument that determines when the symptom condition becomes true.

An alert definition comprises one or more symptom sets. If an alert definition requires all of the symptom sets to be triggered before generating an alert, and only one symptom set is triggered, an alert is not generated. If the alert definition requires only one of several symptom sets to be triggered, then the alert is generated even though the other symptom sets were not triggered.

**Recommendations in Alert Definitions**

Recommendations are the remediation options that you provide to your users to resolve the problems that the generated alert indicates.

When you add an alert definition that indicates a problem with objects in your monitored environment, add a relevant recommendation. Recommendations can be instructions to your users, links to other information or instruction sources, or VCF Operations actions that run on the target systems.

## Creating Alert Definitions

The alert definition process includes adding symptoms that trigger an alert and recommendations that help you resolve the alert. The alert definitions you create with this process are saved to your VCF Operations Alert Definition Overview list and actively evaluated in your environment based on your configured policies.

You can create or reuse existing symptoms and recommendations while defining an alert definition. If you create symptoms and recommendations, you add them to the definition, and they are added to the symptom and recommendations content libraries for future use. You also activate policies and select notifications for the alerts.

1. To create or edit your alert definitions, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Alerts Definiton** tile.
2. Click **Add** to add a definition, or click the vertical ellipsis and select **Edit** to edit the selected definition.

3. In the **Alert** tab, enter details of the alert.

| Option | Description |
|---|---|
| Name | Name of the alert as it appears when the alert is generated. |
| Description | Description of the alert as it appears when the alert is generated. Provide a useful description for your users. |
| For Tenants | Marks an alert definition as tenant-facing when VCF Operations is integrated with VCF Automation. This exposes the generated alerts within the VCF Automation tenant portal, allowing tenant users to monitor alerts relevant to their own workloads, such as VMs and Region Quotas. After the checkbox is selected, the Base Object Type picker automatically restricts available options to tenant-relevant objects, filtering out infrastructure-level entities such as ESX hosts, datastores, and clusters, that are not relevant to tenant users.<br>Displayed when VCF Operations is integrated with VCF Automation. |
| .Base Object Type | The object type against which the alert definition is evaluated and the alert is generated.<br>The drop-down menu includes all of the object types in your environment. You can define an alert definition based on one object type. |
| Impact | Under Advanced Settings, select the badge that is affected if the alert is generated.<br>You can select a badge based on the impact of the alert.<br>• Health<br>• Risk<br>• Efficiency |
| Criticality | Severity of the alert that is communicated as part of the alert notification.<br>Select one of the following values.<br>• Info. Informational purposes only. Does not affect badge color.<br>• Warning. Lowest level. Displays yellow.<br>• Immediate. Medium level. Displays orange.<br>• Critical. Highest level. Displays red.<br>• Symptom Based. In addition to alert criticality, each symptom includes a defined criticality. Criticality of the alert is determined by the most critical of all of the triggered symptoms. The color is dynamically determined accordingly. It you negate symptoms, the negative symptoms to not contribute to the criticality of a symptom-based alert. |
| Alert Type and Subtype | Select the type and subtype of alert.<br>This value is metadata that is used to classify the alert when it is generated, and the information is carried to the alert, including the alert notification.<br>You can use the type and subtype information to route the alert to the appropriate personnel and department in your organization. |

| Option | Description |
|---|---|
| Wait Cycle | The symptoms included in the alert definition remain triggered for this number of collection cycles before the alert is generated.<br>The value must be 1 or greater.<br>This setting helps you adjust for sensitivity in your environment. The wait cycle for the alert definition is added to the wait cycle for the symptom definitions. In most definitions you configure the sensitivity at the level of symptom level and configure the wait cycle of alert definition to 1. This configuration ensures that after all of the symptoms are triggered at the desired symptom sensitivity level, the alert is immediately triggered. |
| Cancel Cycle | The symptoms are cancelled for this number of collection cycles after which the alert is cancelled.<br>The value must be 1 or greater.<br>This setting helps you adjust for sensitivity in your environment. The cancel cycle for the alert definition is added to the cancel cycle for the symptom definitions. In most definitions you configure the sensitivity at the level of symptom level and configure the wait cycle of the alert definition to 1. This configuration ensures that after all of the symptom conditions disappear after the desired symptom cancel cycle, the alert is immediately canceled. |

4. Click **Next** to add symptom definitions.
5. In the **Symptoms/Conditions**tab, drag the selected symptom/condition in to the left pane. Use the workspace on the left to specify whether all or any of the symptoms/conditions or symptom/condition sets must be true to generate an alert. As you add one or more symptoms, you create a symptom expression. If this expression is evaluated as true, then the alert is generated. You can similarly define one or more conditions for your alert, and when the conditions are met, the alert is generated. You can view the alert in the All Alerts page.

**Table 1204: Add Symptoms/Conditions Selection Options**

| Option | Description |
|---|---|
| Defined On | Object that the symptom evaluates.<br>As you create alert definitions, you can select or define symptoms for the base object type and for related object types, based on the object relationship hierarchy. The following relationships are object types as they relate to the alert definition base object type.<br>• Self. A base object type for the alert definition. For example, host system.<br>• Descendant. An object type that is at any level below the base object type, either a direct or indirect child object. For example, a virtual machine is a descendant of a host system.<br>• Ancestor. An object type that is one or more levels higher than the base object type, either a direct or indirect parent. For example, a data center and a vCenter are ancestors of a host system.<br>• Parent. An object type that is in an immediately higher level in the hierarchy from the base object type. For example, a data center is a parent of a host system.<br>• Child. An object type that is one level below the base object type. For example, a virtual machine is a child of a host system. |
| Filter by Object Type | Available only when you select a Defined On value other than Self.<br>Limits the symptoms to those that are configured for the selected object type based on the selected Defined On relationship. |

| Option | Description |
| --- | --- |
| Conditions tab | |
| Select Specific Object | Select a specific object based on its object type, adapter type, policy, collection state, and status. |
| Search | Search the metrics based on object type. |
| Conditions list | List of metrics for the selected object type. To configure a condition, drag it into the left workspace. |
| Log based condition | Create a log based condition without creating a log based symptom first. To configure a condition, drag it into the left workspace. You can combine metric based condition and log based condition to create an advanced alert trigger set.<br>Displayed if Log Management is installed. |
| Symptoms tab | |
| Select Symptom | Select the type of symptom definition that you are adding for the current Defined On object type.<br>• Metric / Property. Add symptoms that use metric and property symptoms. These metrics are based on the operational or performance values, and configuration properties that collects from target objects in your environment.<br>• Message Event. Add symptoms that use message event symptoms. These symptoms are based on events received as messages from a component of VCF Operations or from an external monitored system through the system's REST API.<br>• Fault Event. Add symptoms that use fault symptoms. These symptoms are based on events that monitored systems publish. VCF Operations correlates a subset of these events and delivers them as faults. Faults are intended to signify events in the monitored systems that affect the availability of objects in your environment.<br>• Logs. Select the log based symptoms which you have defined after integration with Log management . You can combine metric and log based symptoms in one alert definition. If you do not want to create a Log based symptom for the alert, you can use a log based Condition.<br>Dsiplayed when Log Management is deployed.<br>• Smart Early Warning. Add a symptom that uses a defined condition that is triggered when the number of anomalies on an object is over the trending threshold. This symptom represents the overall anomalous behavior of the object. Anomalies are based on VCF Operations analysis of the number of applicable metrics that violate the dynamic threshold that determines the normal operating behavior of the object. This symptom is not configurable. You either use it or you do not use it. |
| Create New Symptom | If symptoms that you need for your alert do not exist, you can create them.<br>Opens the symptoms definition dialog box.<br>Not available for Smart Early Warning symptoms, which are predefined in the system. |

| Option | Description |
|---|---|
| All Filters | Filter the list of symptom definitions.<br>• Symptom. Type text to search on the name of the symptom definitions. For example, to display all symptom definitions that have efficiency in their name, type `Efficiency`.<br>• Defined By. Type text to search for the name of the adapter that defines the symptom definitions. For example, to display all symptom definitions provided by the vCenter Adapter, type `vCenter`. To display only user-defined symptom definitions, type the search term `User`.<br>To clear a filter, click the 'x' that appears next to the filter name. |
| Symptoms list | List of existing symptoms for the selected object type. To configure a symptom, drag it into the left workspace.<br>To combine symptoms that are based on multiple levels in the hierarchy, select the new Defined On level and Filter by Object Type before you select and drag the new symptom to the workspace. |

Use the workspace to configure the interaction of the symptoms, symptom sets, and conditions.

**Table 1205: Symptom Sets in the Alert Definition Workspace**

| Option | Description |
|---|---|
| Trigger alert when {operator} of the symptom sets are true | Select the operator for all of the added symptom/condition sets. Available only when you add more than one symptom/condition set.<br>• All. All of the symptom/condition sets must be true before the alert is generated. Operates as a Boolean AND.<br>• Any. One or more of the symptom/condition sets must be true before the alert is generated. Operates as a Boolean OR. |
| Symptoms | The symptom/condition sets comprise an expression that is evaluated to determine if an alert should be triggered.<br>To add one or more symptoms from the symptom list to an existing symptom set, drag the symptom from the list to the symptom set. To create a new symptom set for the alert definition, drag a symptom to the landing area outlined with a dotted line. |

| Option | Description |
| --- | --- |
| Symptom sets | Add one or more symptoms to the workspace, define the points at which the symptom sets are true, and specify whether all or any of the symptoms in the symptom set must be true to generate the alert.<br>A symptom set can include one or more symptoms/conditions, and an alert definition can include one or more symptom/condition sets.<br>If you create a symptom set where the Defined On object is Self, you can set the operator for multiple symptoms in the symptom set.<br>If you create a symptom set where the Defined On object is a relationship other than Self, you can set the operator and modify the triggering threshold. To configure the symptom set criteria, you set the options.<br>• Value operator. Specifies how the value you provide in the value text box is compared to a number of related objects to evaluate the symptom/condition set as true.<br>• Value text box. Number of objects of the specified relationship, based on the value type, that are required to evaluate the symptom/condition set as true.<br>• Value type. Possible types include the following items:<br>– Count. Exact number of related objects meet the symptom/condition set criteria.<br>– Percent. Percentage of total related objects meet the symptom/condition set criteria.<br>– Any. One or more of the related objects meet the symptom/condition set criteria.<br>– All. All of the related objects meet the symptom/condition set criteria.<br>• Symptom set operator. Operator applied between symptoms/conditions in the symptom set.<br>– All. All of the symptoms/conditions must be true before the alert is generated. Operates as a Boolean AND.<br>– Any. One or more of the symptoms/condition must be true before the alert is generated. Operates as a Boolean OR.<br>When you include a symptom in a symptom set, the condition must become true to trigger the symptom set. However, you might want to configure a symptom set where the absence of a symptom condition triggers a symptom. To use the absence of the symptom condition, click the vertical ellipsis on the left of the symptom name and select **Invert Symptom**.<br>Although you can configure symptom criticality, if you invert a symptom, it does not have an associated criticality that affects the criticality of generated alerts. |

**Table 1206: Conditions in the Alert Definition Workspace**

| Option | Description |
|---|---|
| Alert is triggered when {operator} of the sets are true | Select the operator for all of the added condition sets. Available only when you add more than one condition set.<br>• All. All of the condition sets must be true before the alert is generated. Operates as a Boolean AND.<br>• Any. One or more of the condition sets must be true before the alert is generated. Operates as a Boolean OR. |
| Conditions | The condition sets comprise an expression that is evaluated to determine if an alert should be triggered.<br>• Condition. Determines how the value you specify in the value text box is compared to the current value of the metric or property when the condition is evaluated.<br>• Value. Value that specifies the threshold.<br>• Criticality level. Severity of the symptom/condition when it is triggered.<br>• Wait Cycle. The trigger condition should remain true for this number of collection cycles before the symptom/condition is triggered. The default value is 1, which means that the symptom/condition is triggered in the same collection cycle when the condition became true.<br>**Note:**<br>You cannot edit the wait cycle while defining conditions for Properties and Population.<br>• Cancel Cycle. The symptom/condition is canceled after the trigger condition is false for this number of collection cycles after which the symptom/condition is cancelled. The default value is 1, which means that the symptom/condition is canceled in the same cycle when the condition becomes false.<br>**Note:**<br>You cannot edit the cancel cycle while defining conditions for Properties and Population.<br>To add one or more conditions from the condition list to an existing symptom/condition set, drag the condition from the list to the symptom/condition set. |

6. Click **Next** to add recommendations.
7. In the **Recommendations** tab, drag the selected recommendation in to the left pane. Use the workspace on the left to to change the priority order.

**Table 1207: Add Recommendations Options in the Alert Definition Workspace**

| | |
|---|---|
| Create New Recommendation | If recommendations that you need to resolve the symptoms of the problem do not exist, you can create them. |
| All Filters | Filter the list of recommendations.<br>• Description. Type text to search on the name of the recommendation. For example, to display all recommendations that have memory in their name, type `Memory`.<br>• Defined By. Type text to search for the name of the adapter that defines the recommendation. For example, to display all recommendations provided by the vCenter Adapter, type `vCenter`.<br>To clear a filter, click the double arrow icon that appears next to the filter name. |
| Quick filter (Name) | Limits the list based on the text you enter. |

| | |
|---|---|
| List of available recommendations. | List of existing recommendations that you can drag to the workspace.<br>Recommendations are instructions and, where possible, actions that assist you with resolving alerts when they are triggered. |
| Recommendation workspace | Add one or more recommendations to the workspace.<br>If you add more than one recommendation, you can drag the recommendations to change the priority order. |

8. Click **Next** to activate policies.
9. In the **Policies** tab, you can view and select only active policies.

   **Note:**
   If you create an alert without enabling any policies, then the alert remains inactive.
10. Click **Create** to create the alert. The new alert appears in the list of alert definitions.

## Symptom Definitions in VCF Operations

Symptoms are conditions that indicate problems in your environment. You can define symptoms in VCF Operations and add them to alert definitions so that you know when a problem occurs with your monitored objects.

As data is collected from your monitored objects, the data is compared to the defined symptom condition. If the condition is true, then the alert is triggered.

To define symptoms, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definiton** tile under the **Alerts** section.

You can define symptoms based on:

- Metric/Property Symptom
- Message Events Symptoms
- Fault Symptoms
- Logs Symptoms

The symptoms defined in your environment are managed in the Symptom Definitions. When the symptoms that are added to an alert definition evaluate as true, an alert is triggered.

**Define Symptoms to Cover All Possible Severities and Conditions**

Use a series of symptoms to describe incremental levels of concern. For example, `Volume nearing capacity limit` might have a severity value of Warning while `Volume reached capacity limit` might have a severity level of Critical. The first symptom is not an immediate threat. The second symptom is an immediate threat.

## Defining Symptoms for Alerts

The symptoms defined in your environment are managed in the **Symptom Definitions** page.

You can create a symptom definition while creating an alert definition or from the **Symptom Definitions** page.

You can define symptoms based on:

- Metric/Property
- Message Events
- Fault
- Logs

## Metric/Property Symptoms

Metric/Property symptoms are based on the operational/performance values or the configuration properties that VCF Operations collects from target objects in your environment.

**Metric Symptom Definitions**

You can configure the symptoms to evaluate static thresholds or dynamic thresholds. You define symptoms based on metrics so that you can create alert definitions that let you know when the performance of an object in your environment is adversely affected.

**Static Thresholds**

Metric symptoms that are based on a static threshold compare the currently collected metric value against the fixed value you configure in the symptom definition.

For example, you can configure a static metric symptom where, when the virtual machine CPU workload is greater than 90, a critical symptom is triggered.

**Dynamic Thresholds**

Metric symptoms that are based on dynamic thresholds compare the currently collected metric value against the trend identified by VCF Operations , evaluating whether the current value is above, below, or generally outside the trend.

For example, you can configure a dynamic metric symptom where, when the virtual machine CPU workload is above the trended normal value, a critical symptom is triggered.

The Metric Symptom Definitions is a list of the metric-based symptoms defined in your VCF Operations environment. You use the information in the list to evaluate the defined metric threshold triggering states and determine if you want to add, edit, or clone symptoms.

**Property Symptom Definitions**

You define symptoms based on properties so that you can create alert definitions that let you know when changes to properties on your monitored objects can affect the behavior of the objects in your environment.

The Property Symptom Definitions is a list of the property-based symptoms in your VCF Operations environment. You use the information in the list to evaluate the defined property triggering states and determine whether to add, edit, or clone symptoms.

### Where You Find Metric/Property Symptoms

To manage symptoms based on metrics/properties, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile. From the **Symptom Definitions** page, click the **Metric / Property** tab.

You can also define symptoms as you are defining alerts in the Alert Definition Workspace.

**Table 1208: Metric/Property Symptoms Options**

| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your symptoms. You can select multiple symptoms using Ctrl+click or Shift+click.<br>• Add. Add a symptom definition.<br>Click the horizontal ellipsis to perform the following actions on multiple symptom definitions or click the vertical ellipsis against a symptom definition to perform the action on a single symptom definition.<br>• Edit. Modify the selected symptom definition. Any changes you make affect the alert definitions that include this symptom. You cannot edit a symptom that manages a badge.<br>• Delete. Remove the selected symptom definition. You cannot delete an alert that is used in an alert definition. To delete a symptom, you must first remove it from the alert definitions in which it is used. You cannot delete a symptom that manages a badge.<br>• Clone. Create a copy of the selected symptom definition.<br>• Export. Downloads the symptom definition.<br>• Import. Allows you to import symptom definitions. This option is available only when you click the horizontal ellipsis. To import:<br>– Click the **Import** option from the horizontal ellipsis.<br>– Click **Browse** and select the file to import.<br>– Select if you want to Overwrite or Skip the file in case of a conflict.<br>– Click **Import** to import the symptom definition, and click **Done**. |
| Filter options | Limits the list based on the text you type.<br>You can also sort on the columns in the data grid. |
| Name | Descriptive name of the symptom. |
| Criticality | Severity of the symptom when it is triggered. |
| Object Type | Base object type against which the symptom is defined. |
| Metric Name | Text string that is used as a reference key for the metric. You can use the metric key to locate additional information about how the system statistics are derived from the metric. |
| Operator | Operator used to compare the current value to the threshold value, and trigger the symptom. |
| Value | Text string that is the compared value for the property. |
| Defined By | Indicates whether the symptom was created by a user or provided with a solution adapter. |
| Last Modified | Displays the date on which the symptom was last modified. |
| Modified By | Displays the name of the user who last modified the symptom. |

## Defining Metric/Property Symptoms

A metric symptom is triggered when a metric is compared to the configured static or dynamic thresholds, and the symptom condition is evaluated as true in VCF Operations .

## Defining Metric Symptoms

If the symptom is based on a static threshold, the metric is compared based on the configured operator and the provided numeric value. If the symptom is based on a dynamic threshold, the metric is compared based on whether the current value is above, below, or abnormal compared to the calculated trend value.

1. To define symptoms based on metrics, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile. From the **Symptom Definitions** page, click the **Metric / Property** tab. Click **Add** to define a metric-based symptom in the workspace.
2. Enter the following details.

| Option | Description |
|---|---|
| Base Object Type | Object against which the symptom is evaluated.<br>Based on the select object type, the list of available metrics displays only the metrics applicable to the object type. |
| Symptom Type | Select **Metrics** from the Symptom Type drop-down list. |
| Select Specific Object | If a metric or supermetric is not listed in the common metric or supermetric list, based on the selected based object type, use Select Object to inspect the metrics or supermetrics of a selected object so that you can locate the property that you must use to create the symptom. Even though you select a metric or supermetric for a specific object, the symptom definition is applicable to all objects with that metric or supermetric in your environment. |
| Search | Use a word search to limit the number of items that appear in the list. |
| Metric list | List of metrics for the selected base object type.<br>Click and drag the metric to the left pane. |
| Symptom Definition workspace<br>You can define symptoms based on static or dynamic thresholds. | |
| Threshold | Determines if the symptom is static or dynamic.<br>• Static thresholds are fixed values that trigger symptoms as true. You can configure one threshold for each symptom. You can also create multiple symptoms for multiple thresholds.<br>For example, configure one symptom where the CPU use is greater than 90 percent and another where the CPU usage is less than 40 percent. Each is a separate symptom and can be added individually to an alert definition.<br>• Dynamic thresholds are based on VCF Operations trended data where the triggering value is determined through the analytics. If the current value of the metric does not fall in the trended range, the symptom is triggered. |

| Option | Description |
| --- | --- |
| Static Threshold configuration options | If you select Static Threshold, configure the options for this threshold type.<br>• Symptom name. Name of the symptom as it appears in the symptom list when configuring an alert definition, as it appears when the alert is generated, and when viewing triggered symptoms.<br>• Condition. Determines how the value you specify in the value text box is compared to the current value of the metric when the symptom is evaluated.<br>• Value. Value that the condition evaluates.<br>• Criticality. Severity of the symptom when it is triggered.<br>• Wait Cycle. The trigger condition should remain true for this number of collection cycles before the symptom is triggered. The default value is 1, which means that the symptom is triggered in the same collection cycle when the condition became true.<br>• Cancel Cycle. The symptom is canceled after the trigger condition is false for this number of collection cycles after which the symptom is cancelled. The default value is 1, which means that the symptom is canceled in the same cycle when the condition becomes false.<br>• Evaluate on instanced metrics. Select this check box so that the system evaluates the object level symptom as well as the instance level symptom. For example, for CPU usage, when the check box is not selected, the symptom is triggered based on the object's CPU usage. However, if you select the check box, the system also evaluates CPU usage of each of the cores. If any of the cores is found to be crossing the threshold, the symptom is triggered.<br>• Exclude the following instances of the metric. To exclude specific instanced metrics from the symptom, drag the metric instances from the left pane. If you cannot locate the metric instance you want to exclude, you can search for it in another object that uses the metric by clicking **Select Specific Object** next to the search box. |

| Option | Description |
|---|---|
| Dynamic Threshold configuration options | If you select Dynamic Threshold, configure the options for this threshold type.<br>• Symptom name. Name of the symptom as it appears in the symptom list when configuring an alert definition, as it appears when the alert is generated, and when viewing triggered symptoms.<br>• Condition. Relationship of the current value to trended range based on the following options:<br>– Above Threshold. If current value is above trended range, the symptom is triggered.<br>– Below Threshold. If the current value is below the trended range, the symptom is triggered.<br>– Abnormal. If the current value is either above or below the trended range, the symptom is triggered.<br>• Criticality. Severity of the symptom when it is triggered.<br>• Evaluate on instanced metrics. Select this check box so that the system evaluates the object level symptom as well as the instance level symptom. For example, for CPU usage, when the check box is not selected, the symptom is triggered based on the object's CPU usage. However, if you select the check box, the system also evaluates CPU usage of each of the cores. If any of the cores is found to be crossing the threshold, the symptom is triggered.<br>• Exclude the following instances of the metric. To exclude specific instanced metrics from the symptom, drag the metric instances from the left pane. If you cannot locate the metric instance you want to exclude, you can search for it in another object that uses the metric by clicking **Select Object** next to the **Metrics** field. |

3. Click **Save**.

## Defining Property Symptom

A property symptom is triggered when the defined threshold is compared with the current property value and the comparison is evaluated as true.

1. To define symptoms based on properties, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile. From the **Symptom Definitions** page, click the **Metric / Property** tab. Click **Add** to define a property-based symptom in the workspace.
2. Enter the following details.

| Option | Description |
|---|---|
| Base Object Type | Object against which the symptom is evaluated.<br>Based on the selected object type, the list of available properties displays only the properties applicable to the object type. |
| Symptom Type | Select **Properties** from the Symptom Type drop-down list. |
| Select Specific Object | If a property is not listed in the common properties list, based on the selected based object type, use Select Object to inspect the properties of a selected object so that you can locate the property that you must use to create the symptom. Even though you select a property for a specific object, the symptom definition is applicable to all objects with that property in your environment. |
| Search | Use a word search to limit the number of items that appear in the list. |

| Option | Description |
|---|---|
| Property list | List of properties for the selected base object type.<br>Click and drag the property to the left pane. |
| Symptom Definition workspace<br>The properties are configured values that are compared to the value you specify. You can configure a single property symptom or add multiple symptoms.<br>For example, if you need an alert when a particular property, such as Memory Hot Add, is no longer at the value required, you can configure a symptom and add it to an alert definition. | |
| Property | Configure the options:<br>• Symptom name. Name of the symptom as it appears in the symptom list when configuring an alert definition, as it appears when the alert is generated, and when viewing triggered symptoms.<br>• Condition. Determines how the value you specify in the value text box is compared to the current value of the property for an object when the symptom definition is evaluated.<br>• Value. Value that the condition evaluates.<br>• Criticality. Severity of the symptom when it is triggered.<br>• Wait Cycle. The trigger condition should remain true for this number of collection cycles before the symptom is triggered. The default value is 1, which means that the symptom is triggered in the same collection cycle when the condition became true.<br>• Cancel Cycle. The symptom is canceled after the trigger condition is false for this number of collection cycles after which the symptom is cancelled. The default value is 1, which means that the symptom is canceled in the same cycle when the condition becomes false.<br>• Evaluate on instanced properties. Select this check box so that the system evaluates the object level symptom as well as the instance level symptom. For example, for memory usage, when the check box is not selected, the symptom is triggered based on the object's memory usage. However, if you select the check box, the system also evaluates memory usage of each of the cores. If any of the cores is found to be crossing the threshold, the symptom is triggered.<br>• Drop instances to exclude. To exclude specific instanced properties from the symptom, drag the property instances from the right pane. If you cannot locate the property instance you want to exclude, you can search for it in another object that uses the property by clicking **Select Specific Object** next to the search box. |

3. Click **Save**.

## Message Event Symptoms

Message event symptoms are based on events received as messages from a component of VCF Operations or from an external monitored system through the system's REST API. You define symptoms based on message events to include in alert definitions that use these symptoms. When the configured symptom condition is true, the symptom is triggered.

The adapters for the external monitored systems and the REST API are inbound channels for collecting events from external sources. Adapters and the REST server both run in the system. The external system sends the messages, and VCF Operations collects them.

You can create message event symptoms for the supported event types. The following list is of supported event types with example events.

- System Performance Degradation. This message event type corresponds to the EVENT_CLASS_SYSTEM and EVENT_SUBCLASS_PERFORM_DEGRADATION type and subtype in the VCF Operations API SDK.

- Change. The VMware adapter sends a change event when the CPU limit for a virtual machine is changed from unlimited to 2 GHz. You can create a symptom to detect CPU contention issues as a result of this configuration change. This message event type corresponds to the EVENT_CLASS_CHANGE and EVENT_SUBCLASS_CHANGE type and subtype in the VCF Operations API SDK.
- Environment Down. The VCF Operations adapter sends an environment down event when the collector component is not communicating with the other components. You can create a symptom that is used for internal health monitoring. This message event type corresponds to the EVENT_CLASS_ENVIRONMENT and EVENT_SUBCLASS_DOWN type and subtype in the VCF Operations API SDK.
- Notification. This message event type corresponds to the EVENT_CLASS_NOTIFICATION and EVENT_SUBCLASS_EXTEVENT type and subtype in the VCF Operations API SDK.

**Where You Find Message Event Symptoms**

To manage symptoms based on message events, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile. From the **Symptom Definitions** page, click the **Message Event** tab.

You can also define symptoms as you are defining alerts in the Alert Definition Workspace.

The Message Event Symptom Definitions is a list of the message event-based symptoms defined in your VCF Operations environment. You use the information in the list to evaluate the defined message events and to determine if you want to add, edit, or clone symptoms.

| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your symptoms. You can select multiple symptoms using Ctrl+click or Shift+click.<br>• Add. Add a symptom definition.<br>Click the horizontal ellipsis to perform the following actions.<br>• Edit. Modify the selected symptom definition. Any changes you make affect the alert definitions that include this symptom. You cannot edit a symptom that manages a badge.<br>• Delete. Remove the selected symptom definition. You cannot delete an alert that is used in an alert definition. To delete a symptom, you must first remove it from the alert definitions in which it is used. You cannot delete a symptom that manages a badge.<br>• Clone. Create a copy of the selected symptom definition.<br>• Export and Import. Export the file as xml from one VCF Operations so that you can import the file on another instance. When you import the file, if you encounter a conflict, you can override the existing file or not import the new file. |
| Filter options | Limits the list based on the text you type.<br>You can also sort on the columns in the data grid. |
| Name | Descriptive name of the symptom. |
| Adapter Type | Adapter type for which the symptom is configured. |
| Object Type | Base object type against which the symptom is defined. |
| Event Type | Defined event classification type. |
| Operator | Operator used to compare the message from the incoming event against the event message specified in the symptom. |
| Event Message | Text string that is compared to the message in the incoming event using the specified operator. |
| Criticality | Severity of the symptom when it is triggered. |
| Defined By | Indicates whether the symptom was created by a user or provided with a solution adapter. |

| Option | Description |
|---|---|
| Last Modified | Displays the date on which the symptom was last modified. |
| Modified By | Displays the name of the user who last modified the symptom. |

## Defining Message Events

You can define message event systems in VCF Operations so that you can create one or more of the symptoms that you can add to an alert definition. A message event symptom is triggered when a message in an incoming event matches the text string in the symptom, based on the specified operator.

1. To define symptoms based on message events, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile.
2. Select the **Message Event** tab, and then click **Add**.

   **Note:**
3. Enter the following details.

**Table 1209: Symptoms Workspace Options for Message Events**

| Option | Description |
|---|---|
| Based Object Type | Object against which the symptom is evaluated. |
| Symptom Type | Displays the symptom type as **Message Event**. |
| Select the Type of Event | Select the type of incoming event against which you are matching the events as they arrive. The incoming event must contain the following type and subtype combinations.<br>• System Degradation<br>• Change<br>• Environment<br>• Notification<br>• Data Availability<br>• Collector Down<br>• Object Error<br>Click and drag the message event to the left pane. |
| Symptom Definition workspace<br>The Message Event text string is compared to the message in the incoming event by using the specified operator. You can configure a single message event symptom or add multiple symptoms.<br>For example, the VMware adapter sends a change event when the CPU limit for a virtual machine was changed from unlimited to 2 GHz. You can create a symptom to detect CPU contention issues as a result of this configuration change. | |
| Message Event | Configure the options:<br>• Symptom name. Name of the symptom as it appears in the symptom list when configuring an alert definition, as it appears when the alert is generated, and when viewing triggered symptoms.<br>• Condition. Determines how the value you specify in the value text box is compared to the current value of the property for an object when the symptom definition is evaluated.<br>• Value. Value that the condition evaluates.<br>• Criticality. Severity of the symptom when it is triggered. |

4. Click **Save**.

# Fault Symptoms

Fault symptoms are based on events published by monitored systems. VCF Operations correlates a subset of these events and delivers them as faults. Faults are intended to signify events in the monitored systems that affect the availability of objects in your environment. You define symptoms based on faults to include in alert definitions that use these symptoms. When the configured symptom condition is true, the symptom is triggered.

You can create fault symptoms for the supported published faults. Some object types have multiple fault definitions from which to choose, while others have no fault definitions.

If the adapter published fault definitions for an object type, you can select one or more fault events for a given fault while you define the symptom. The symptom is triggered if the fault is active because of any of the chosen events. If you do not select a fault event, the symptom is triggered if the fault is active because of a fault event.

## Where You Find Fault Symptoms

To manage symptoms based on fault message events, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile. From the **Symptom Definitions** page, click the **Fault** tab.

You can also define symptoms as you are defining alerts in the Alert Definition Workspace.

The Fault Symptom Definitions is a list of the fault-based symptoms defined in your VCF Operations environment. You use the information in the list to evaluate the defined fault message events and to determine whether to add, edit, or clone symptoms.

| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your symptoms. You can select multiple symptoms using Ctrl+click or Shift+click.<br>• Add. Add a symptom definition.<br>Click the horizontal ellipsis to perform the following actions.<br>• Edit. Modify the selected symptom definition. Any changes you make affect the alert definitions that include this symptom. You cannot edit a symptom that manages a badge.<br>• Delete. Remove the selected symptom definition. You cannot delete an alert that is used in an alert definition. To delete a symptom, you must first remove it from the alert definitions in which it is used. You cannot delete a symptom that manages a badge.<br>• Clone. Create a copy of the selected symptom definition.<br>• Export and Import. Export the file as xml from one VCF Operations so that you can import the file on another instance. When you import the file, if you encounter a conflict, you can override the existing file or not import the new file. |
| Filter options | Limits the list based on the text you type.<br>You can also sort on the columns in the data grid. |
| Name | Descriptive name of the symptom. |
| Adapter Type | Adapter type for which the symptom is configured. |
| Object Type | Base object type against which the symptom is defined. |
| Fault | Selected fault based on object type. |
| Defined By | Indicates whether the symptom was created by a user or provided with a solution adapter. |
| Last Modified | Displays the date on which the symptom was last modified. |
| Modified By | Displays the name of the user who last modified the symptom. |

### Defining Fault Symptoms

You can define fault symptoms in VCF Operations that are based on events published by the monitored systems, so that you can add one or more symptoms to an alert definition. A fault symptom is triggered when a fault is active on the base object because of the occurrence of any of the fault events selected in the symptom definition.

1. To define symptoms based on fault message events, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile.
2. Select the **Fault** tab and then, click **Add**.
3. Enter the following details.

| Option | Description |
|---|---|
| Based Object Type | Object against which the symptom is evaluated. |
| Symptom Type | Displays the symptom type as **Fault**. |
| Fault Definitions | Select the fault definition for the selected base object type. Some object types do not have fault definitions, and other types have multiple definitions.<br>Click and drag the fault definition to the left pane. |
| Symptom Definition workspace<br>The fault events are published events from monitored systems. You can configure a single fault event symptom or add multiple symptoms.<br>For example, if your base object is host and you drag the Hardware sensor fault for unknown type fault definition, you then select one of two text strings indicating a fault. | |
| Fault Symptom | Configure the options:<br>• Symptom name. Name of the symptom as it appears in the symptom list when configuring an alert definition, as it appears when the alert is generated, and when viewing triggered symptoms.<br>• Value. Select one or more fault events that activate the fault. If you do not select a string, then any of the provided strings are evaluated.<br>• Criticality. Severity of the symptom when it is triggered. |

4. Click **Save**.

## Logs Symptoms

You can create symptoms in VCF Operations based on events ingested by Log management. You can then configure alerts to use the log based symptoms. Previously you had to create and manage alerts in VMware Aria Operations for Logs and VMware Aria Operations separately. Now, VCF Operations provides a unified experience to define log based symptoms and alerts. The prerequisite is the integration between Log management and VCF Operations. For more details, see Configuring and Analyzing Logs.

When you define a symptom in VCF Operations, an alert definition is created in Log management. You must define the query, trigger conditions and the objects on which these conditions must be met. Since Log management does not have a concept of objects, the object scope for the symptom definition is limited to vCenter objects. To define symptoms for other types of objects, use the Log Fallback Object option.

When the alert is triggered in Log management, an event is generated in VCF Operations. VCF Operations processes this event based on the corresponding symptom definition and triggers the alert.

> **Note:**
>
> It can take up to two minutes for the alert definition to be created in Log management after you define a log based symptom in VCF Operations. You cannot modify the alert definition in Log management but can modify it in VCF Operations. For more information, see, Creating Alert Definitions.

To define log based symptoms, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Symptom Definitons** tile. Select the **Logs** tab. Click the **ADD** button to define a Logs based symptom.

**Note:**

If the list of of symptoms is empty and the **Add** button is not available, verify that the prerequisite of integration between Log management and VCF Operations is met.

| Option | Description |
|---|---|
| Base Object Type | Since the alert definition is triggered in Log management , only the following limited set of objects can be selected. They are:<br>• vCenter<br>– Host System<br>– vCenter<br>– Virtual Machine<br>If you want to create a symptom definition for other object types, then select:<br>• Container<br>– Log Fallback Object |
| Symptom Type | Drag and drop the Logs symptom type to the left workspace of the page to continue to the definition. |
| Symptom Trigger Condition | 1. Provide a name for the symptom.<br>2. Define the criticality of the event based on the function and condition.<br>3. Select a time period and group the symptom by static or extracted fields.<br>4. Select a query from the drop-down list or enter a text to search for to filter by.<br>5. Optionally, select a partition to include in the scope of the search.<br>6. Optionally, add more filters.<br>7. Click **SAVE** |

Once you define a symptom, you can create an alert for the same object for which you created the symptom. To define an alert, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations** and then click the **Alerts Definitions** tile. For more information, see, Creating Alert Definitions.

## Understanding Negative Symptoms for VCF Operations Alerts

Alert symptoms are conditions that indicate problems in your environment. When you define an alert, you include symptoms that generate the alert when they become true in your environment. Negative symptoms are based on the absence of the symptom condition. If the symptom is not true, the symptom is triggered.

To use the absence of the symptom condition in an alert definition, you negate the symptom in the symptom set.

All defined symptoms have a configured criticality. However, if you negate a symptom in an alert definition, it does not have an associated criticality when the alert is generated. If the symptom is triggered because the condition is true, the symptom criticality will be the same as the configured criticality.

When negative symptoms are triggered and an alert is generated, the effect on the criticality of the alert depends on how the alert definition is configured.

The following table provides examples of the effect negative symptoms have on generated alerts.

**Table 1210: Negative Symptoms Effect on Generated Alert Criticality**

| Alert Definition Criticality | Negative Symptom Configured Criticality | Standard Symptom Configured Criticality | Alert Criticality When Triggered |
|---|---|---|---|
| Warning | One Critical Symptom | One Immediate Symptom | Warning. The alert criticality is based on the defined alert criticality. |
| Symptom Based | One Critical Symptom | One Warning Symptom | Warning. The negative symptom has no associated criticality and the criticality of the standard symptom determines the criticality of the generated alert. |
| Symptom Based | One Critical Symptom | No standard symptom included | Info. Because an alert must have a criticality and the negative alert does not have an associated criticality, the generated alert has a criticality of Info, which is the lowest possible criticality level. |

# Recommendations in VCF Operations

Recommendations are probable solutions for an alert generated. You can create a library of recommendations that include instructions to your environment administrators or actions that they can run to resolve an alert.

Recommendations provide your network engineers or virtual infrastructure administrators with information to resolve alerts.

Depending on the knowledge level of your users, you can provide more or less information, including the following options, in any combination.

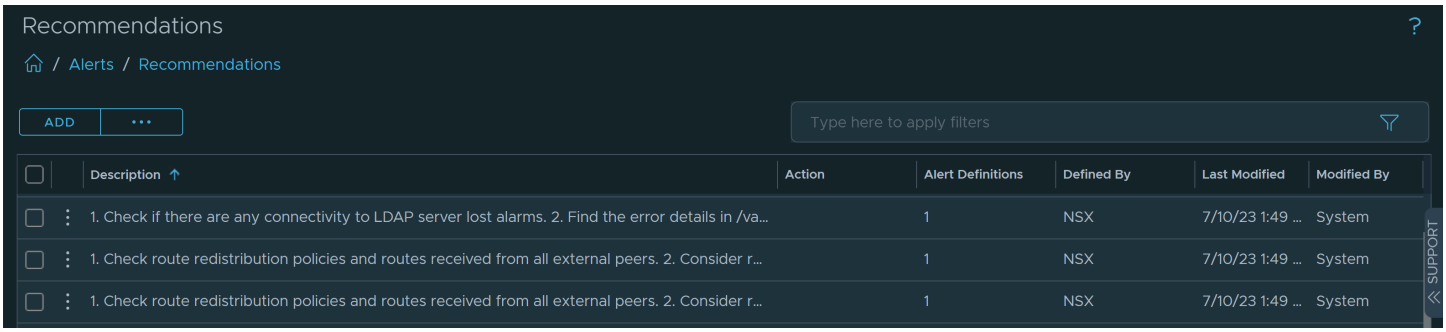
- One line of instruction.
- Steps to resolve the alert on the target object.
- Hyperlink to a Web site, runbook, wiki, or other source.
- Action that makes a change on the target object.

When you define an alert, provide as many relevant action recommendations as possible. If more than one recommendation is available, arrange them in priority order so that the solution with the lowest effect and highest effectiveness is listed first. If no action recommendation is available, add text recommendations. Be as precise as possible when describing what the administrator should do to fix the alert.

### Where You Find Recommendations

To define recommendations, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Recommendations** tile.

You can also define recommendations when you create an alert definition.



| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your recommendations.<br>• Add. Add a recommendation.<br>Click the horizontal ellipsis to perform the following actions.<br>• Edit. Modify the selected recommendation.<br>• Delete. Remove the selected recommendation.<br>• Clone. Create a copy of the selected recommendation so that you can create a new recommendation that uses the current one.<br>• Export. Downloads the recommendations.<br>• Import. Allows you to import recommendations. To import:<br>– Click the **Import** option from the horizontal ellipsis.<br>– Click **Browse** and select the file to import.<br>– Select if you want to Overwrite or Skip the file in case of a conflict.<br>– Click **Import** to import the recommendation, and click **Done**. |
| Quick Filter | Limits the list based on the text you type.<br>You can also sort on the columns in the data grid. |
| Description | Displays the recommendation text that is provided when the alert is generated.<br>Click this link to view the Details Page. On this page, you can view the alert definitions assigned for a particular recommendation. To remove the selected recommendation from all alert definitions, click **Edit** and then, in the **Edit Recommendation** page, click **Remove from all**. |
| Action | If the recommendation includes running an action, the name of the action is displayed. |
| Alert Definitions | Displays the number of alert definitions assigned for a particular recommendation. |
| Defined By | Indicates whether the recommendation was created by a user or provided with a solution adapter. |
| Last Modified | Displays the date on which the recommendation was last modified. |
| Modified By | Displays the name of the user who last modified the recommendation. |

## Defining Recommendations for Alerts

You can create recommendations that are solutions to alerts generated. The recommendations are intended to ensure that your network operations engineers and virtual infrastructure administrators can respond to alerts as quickly and

accurately as possible. A recommendation can contain links to useful Web sites or local runbooks, instructions as text, or actions that you can initiate from VCF Operations.

1. To define recommendations, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Recommendations** tile.
2. Click **Add** and enter the following details.

| Option | Description |
|---|---|
| Description | Enter the description of what must be done to resolve the triggered alert.<br>The description can include steps a user must take to resolve the alert or it might be instructions to notify a virtual infrastructure administrator.<br>This is a text field. |
| Create a hyperlink | To create a hyperlink, enter a description, select the text, and click the Hyperlink icon to make the text a hyperlink to a Website or local wiki page. |
| Action (Optional) | |
| Adapter Type | Select an adapter type from the drop-down list to narrow down the list of actions displayed in the Actions field. |
| Action | You can add an action as a method to resolve a triggered symptom or a generated alert. Actions must already be configured.<br>You must provide text in the text box to describe the action before you can save the recommendation. |

3. Click **Save**.

These actions, named `Delete Unused Snapshots for Datastore Express` and `Delete Unused Snapshots for VM Express` appear. However, they can only be run in the user interface from an alert whose first recommendation is associated with this action. You can use the REST API to run these actions.

The following actions are also not visible except in the alert recommendations:

- `Set Memory for VM Power Off Allowed`
- `Set CPU Count for VM Power Off Allowed`
- `Set CPU Count and Memory for VM Power Off Allowed`

These actions are intended to be used to automate the actions with the `Power Off Allowed` flag set to true.

## Notifications in VCF Operations

Notifications are alert notifications that meet the filter criteria in the notification rules before they are sent outside VCF Operations. You can configure notification rules for the supported outbound alerts so that you can filter the alerts that are sent to the selected external system.

You can use the notifications list to manage your rules and then use the notification rules to limit the alerts that are sent to the external system. To use notifications, the supported outbound alert plug-ins must be added and running.

With notification rules, you can limit the data that is sent to the following external systems.

- Standard Email. You can create multiple notification rules for various email recipients based on one or more of the filter selections. If you add recipients but do not add filter selections, all the generated alerts are sent to the recipients.
- SNMP Trap. You can configure VCF Operations to log alerts on an existing SNMP Trap server in your environment.
- Log File. You can configure log alerts to a file on each of your VCF Operations nodes.

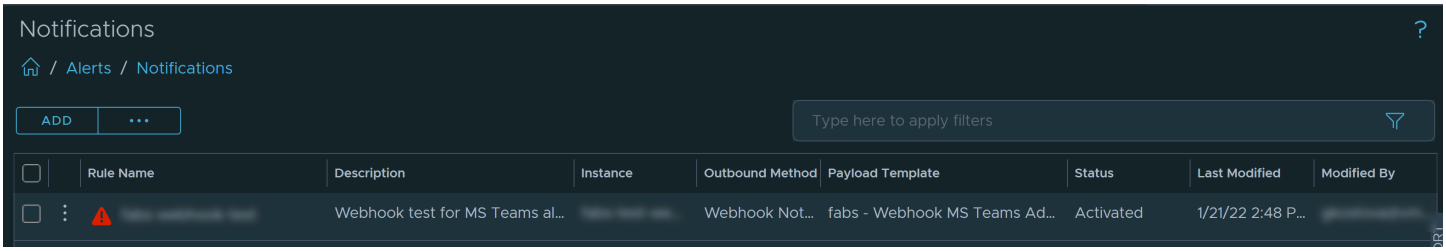
You configure notification options to specify which alerts are sent out for the Standard Email, SNMP, and Log File outbound alert plug-ins. For the other plug-in types, all the alerts are sent when the target outbound alert plug-in is activated.

The most common outbound alert plug-in is the Standard Email plug-in. You configure the Standard Email plug-in to send notifications to one or more users when an alert is generated that meets the criteria you specify in the notification settings.

## Where You Find Notifications

To manage your notifications, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Notifications** tile.

**Note:**
To use notifications, the supported outbound alert plug-ins must be added and running.



| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your notification rules.<br>• Add. Opens the Add Rule dialog box where you configure the filtering options for the notification rule.<br>Click the horizontal ellipsis to perform the following actions.<br>• Delete. Removes the selected rule.<br>• Deactivate or Activate. Deactivates or activates the selected rule(s).<br>• Export or Import. Export the selected notifications to a ".xml" file so that you can import it on another VCF Operations instance. |
| Quick Filter (Action Name) | Limits the list to actions matching the filter. You can filter by:<br>• Rule Name<br>• Instance<br>• Status<br>• Modified By |
| Rule Name | Name you assigned when you created the notification rule. Click the vertical ellipsis to perform the following actions.<br>• Edit. Allows you to edit the selected rule.<br>• Clone. Allows you to clone an existing notification rule and edit the attributes of the cloned notification rule. You can create multiple alert notification rules so that you can send the same alert notifications to different outbound settings.<br>**Note:**<br>You can clone only one alert notification rule at a time.<br>• Delete. Removes the selected rule.<br>• Deactivate or Activate. Deactivates or activates the selected rule.<br>• Export. Downloads the notification setting. |
| Description | Description of the notification rule. |
| Instance | Name of the configured outbound alert instance for the notification rule.<br>Instances are configured as part of the outbound alerts and can indicate different email servers or sender addresses for alert notifications. |
| Outbound Method | Displays the type of the outbound method that is configured. |
| Payload Template | Displays the payload template that is used. |
| Status | Displays if the rule is activated or not. |
| Email Address | If the rule is for standard email notifications, the alert recipient email addresses are listed. |
| Object Name | If the rule specifies a notification for a particular object, the object name is listed. |

| Option | Description |
|---|---|
| Children | If the rule specifies a notification for a particular object and selected child objects, the child object types are listed. |
| Last Modified | Displays the date on which the rule was last modified. |
| Modified By | Displays the name of the user who last modified the rule. |

## Creating Notification Rules for Alerts

You add, manage, and edit your notification rules in VCF Operations. To send notifications to a supported system, you must configure and activate the settings for outbound alerts.

Before you can create and manage your notification rules, you must configure the outbound alert plug-in instances. For details on configuring outbound plug-ins, see Adding Outbound Notification Plug-Ins in VCF Operations.

You use the Notifications page to manage your alert notification rules. The rules determine which VCF Operations alerts are sent to the supported target systems.

Notification rules are filters that limit the data sent to external systems by using outbound alert plug-ins that are supported, configured, and running. Rather than sending all alerts to all your email recipients, you can use notification rules to send specific alerts. For example, you can send health alerts for virtual machines to one or more of your network operations engineers. You can send critical alerts for selected hosts and clusters to the virtual infrastructure administrator for those objects. Before you can create and manage notification rules, you must configure the outbound alert plug-in instances.

1. To manage your notifications, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Notifications** tile. On the toolbar, click **Add** to add a rule, or click the vertical ellipsis and select **Edit** to edit the selected rule.
2. Enter the following notification details.

| Option | Description |
|---|---|
| Name | Name of the rule that you use to manage the rule instance. |
| Description | Description of the rule. |
| Notification Status | Either activate or deactivate a notification setting. Deactivating a notification will stop the alert notification for that setting and activating it will activate the alert notification. |
| Advanced Settings | |
| Notification Type | Select **Alert** from the drop-down menu.<br>**Note:**<br>Select **Action** as your Notification Type if you want to create Workload Placement (WLP) Action based notification. For details, see Creating Notification Rules for Notification Type 'Action'. |

3. Click **Next**.
4. Define criteria for the notification rule.

| Option | Description |
|---|---|
| Object Scope | |
| Criteria | Object Type, Object, Tags, Applications, and Tiers for which you are filtering the alert notifications.<br>After you select the type, you select the specific instance. For example, if you select **Object**, you then select the specific object by name and determine whether to include any child objects. |
| Alert Scope | |

| Option | Description |
|---|---|
| Category | Alert Types/Subtypes, Alert Impact, or Alert Definition that triggers the alert.<br>After you select the criteria, you can configure the specific selections associated with the criteria. For example, if you select **Alert Definition**, you then select the alert definition that limits the data to alerts with this definition. You can select multiple alert definitions as conditions for a notification to trigger. |
| Criticality | Defined criticality of the alert that results in the data being sent to an external system. For example, if you select **Critical**, then the data that is sent to the external system must also be labeled as critical. |
| Control State | State of the alert, either opened, assigned, or suspended. |
| Notify On | |
| Status | Current state of the alert, either canceled, updated, or new. |
| Notification Heartbeat | |
| Heartbeat | Set this to **Active** if you want to send repeat notifications for the active alerts. The frequency of the notification depends on the collection interval set for the adapter whose object is being evaluated. By default, this checkbox is not selected.<br>**Note:**<br>Setting this option to **Active** can cause a potential surge in the notifications that are generated. |
| Advanced Filters: By Collector | |
| Collector/Group | Select a collector or group if you want to receive notifications for the objects that receive data from the selected collector/group. |
| **Note:**<br>If you do not define any alert filters in the Define Criteria tab, then the notification will be sent for all the alerts without applying any conditions for the object scope, alert scope, or alert state. | |

5. Click **Next**.
6. Select the outbound method that you want to use to send your notification.

| Option | Description |
|---|---|
| Outbound Method | • Select Plug-In Type: Type of plugin. Select one of the outbound alert plug-in types: Log File Plugin, Standard Email Plugin, SNMP Trap Plugin, Webhook Notification Plugin, Slack Plugin, and Service-Now Notification Plugin.<br>• Select Instance: Select the configured instance for the type of plug-in.<br>• Create New Instance: You can also create a new outbound instance for the plug-in type you select.<br>For details, see Adding Outbound Notification Plug-Ins in VCF Operations. |

7. Click **Next**.

8. Select the payload template.

| Option | Description |
|---|---|
| Payload Template | Select the payload template that you want to include in the notification. Each plug-in has its default template and you can select the default template if no customization is required. The template includes additional information about the alert or the object that is displayed in the notification. You can also customize your payload for a Webhook Notification Plugin. For details on creating payload templates, see Creating Payload Templates for Outbound Plugins. |
| The values in this tab differ based on the outbound plug-in you have selected in the previous step. | |
| Outbound Method -Standard Email Plugin | If you are configuring notifications for standard email, you can add recipients and associated information.<br>• Recipient(s). Enter the email addresses of the individuals to whom you are sending email messages that contain alert notifications. If you are sending to more than one recipient, use a semicolon (;) between addresses.<br>• Cc Recipients. Enter the email addresses of the individuals that have to be cc'd for the email.<br>• Bcc Recipients. Enter the email addresses of the individuals that have to be bcc'd for the email.<br>• Notify again. Number of minutes between notifications messages for active alerts. Leave the text box empty to send only one message per alert.<br>• Max Notifications. Number of times to send the notification for the active alert. Leave the text box empty to send only one message per alert.<br>• Delay to notify. Number of minutes to delay before sending a notification when a new alert is generated. For example, if the delay is 10 minutes and a new alert is generated, the notification is not sent for 10 minutes. If the alert is canceled in those 10 minutes, the notification is not sent. The notification delay reduces the number of notifications for alerts that are canceled during that time.<br>• Description. Enter the text to include in the email message. For example, the Attention Host Management team. |

| Option | Description |
| --- | --- |
| Outbound Method - Service-Now Notification Plugin | If you are configuring notifications for a Service-Now notification plug-in, you can add instances and associated information.<br>• Caller. Enter the name of the person who reported the incident or who is affected by the incident.<br>• Category. Specify the category to which the incident belongs.<br>• Sub Category. Specify the sub-category to which the incident belongs.<br>• Business Service. Specify the business service of the incident.<br>• Contact Type. Enter the contact type.<br>• State. Enter the incident state in digits.<br>• Resolution Code. Enter the resolution code for the incident.<br>• Resolution notes. Enter the resolution notes for the incident.<br>• On hold reason. Enter the reason as to why the incident is on hold.<br>• Impact. Set the incident impact in digits. Impact measures the business criticality of the affected service.<br>• Urgency. Set urgency for the incident in digits. Urgency defines the number of days taken to resolve an incident.<br>• Priority. Enter the priority for the incident. Priority defines the sequence in which the incident must be resolved.<br>• Assignment Group. Enter the assignment group for the incident.<br>• Assigned To. Enter the details of the person to whom the incident is assigned.<br>• Severity. Set the severity for the incident in digits.<br>• Upon Approval. Specify the next steps to be taken upon incident approval.<br>• Problem. Enter the details of the related problem if it exists.<br>• Cause by change. Enter the change request which triggered the incident.<br>• Change Request. Enter the details for the related change list if it exists. |
| Outbound Method - Slack Plugin | If you are configuring notifications for a Slack plugin, add the Webhook URL of Slack. For example, the Webhook URL is in the format: `https://hooks.slack.com/services/T00000000/B00000000/XXXXXXXXXXXXXXXXXXXXXXXX`.<br>Create and authorize an app within Slack to obtain the Webhook URL. For details on creating and authorizing an app within Slack, refer to the Slack Documentation.<br>Once you have created the notification rule, the alerts are displayed within that particular Slack channel with a link to the alert. Click the link to view the details of the alert on the Object Summary page. |

9. Click **Next** to test the notification
10. In the **Test Notification** tab, click **Initiate Process** to initiate the notification configuration validation process.
11. If you activate the **Filter the alert definitions and objects based on criteria outlined in the Define Criteria section** option, then the alert definitions and objects displayed below are based on the criteria outlined in the **Define Criteria** section.
12. Select an alert definition and an object for validation.
13. Click **Validate Configuration**.

– Notification Validation Steps: View the steps involved in validating the notification configuration. The steps also indicate an error, if any. The validation steps differ based on the selected Outbound method.

| Outbound Method | Validation Steps |
|---|---|
| Log File Plugin | • Validate Criteria<br>• Permissions<br>• File Created |
| Standard Email Plugin | • Validate Criteria<br>• Establish Endpoint Connection<br>• Certificates<br>• Authentication<br>• Send Notification<br>**Note:**<br>The Standard Email Plugin does not provide a response that can be validated. |
| SNMP Trap Plugin | • Validate Criteria<br>• Establish Endpoint Connection<br>• Send Notification<br>**Note:**<br>The SNMP Trap Plugin does not provide a response that can be validated. |
| Webhook Notification Plugin | • Validate Criteria<br>• Establish Endpoint Connection<br>• Certificates<br>• Authentication<br>• Send Notification<br>• Endpoint Receives Notification |
| Slack Plugin | • Validate Criteria<br>• Establish Endpoint Connection<br>• Authentication<br>• Send Notification<br>• Endpoint Receives Notification |
| ServiceNow Notification Plugin | • Validate Criteria<br>• Establish Endpoint Connection<br>• Authentication<br>• Send Notification<br>• Endpoint Receives Notification |

– Response: The Response tab in the right pane displays if the test passed successfully or if there were any errors.
– Body: Displays the content of the notification.

14. Click **Create** to create the notification rule. You can view the rule you created under **Alerts** > **Notifications**.

## Creating Notification Rules for Notification Type 'Action'

You can create and manage Workload Placement (WLP) Action based notification.

You can configure actions for which you want to receive notifications. Once configured, notifications are sent indicating the successful, failed, or timed out WLP action.

**Note:**
The notifications are sent once the WLP Virtual Machine movement task is completed irrespective of its status.

Before you can create and manage your notification rules, you must configure the Webhook Notification Plugin. For details, see Add a Webhook Notification Plugin for Outbound Instance.

To create notification rules for WLP action:

1. in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Notifications** tile. On the toolbar, click **Add** to add a rule, or click the vertical ellipsis and select **Clone** to clone the selected rule.

   **Note:**
   You cannot change the **Notification Type** while editing a selected notification rule,
2. Enter the following notification details.

| Option | Description |
|---|---|
| Name | Name of the rule that you use to manage the rule instance. |
| Description | Description of the rule. |
| Notification Status | Either activate or deactivate a notification setting. Deactivating a notification will stop the notification for that setting and activating it will activate the notification. |
| Advanced Settings | |
| Notification Type | Select **Action** from the drop-down menu. |

3. Click **Next**.
4. Define criteria for the notification rule.

| Option | Description |
|---|---|
| Object Scope: Select set of Objects for which you want to receive notifications. | |
| Criteria | Select the Criteria as **Object** from the drop-down menu.<br>Search for a specific object by name and determine if you want to include any child or descendant objects, and then add one or more child/descendant objects.<br>The action triggers on ANY of the selected objects: |
| Notify On | |
| Status | Select the action status for which you want to receive notification. You can receive notification for **Succeeded**, **Failed**, and **Timed Out** statuses. |

5. Click **Next**.
6. Select the outbound method that you want to use to send your notification.

| Option | Description |
|---|---|
| Outbound Method | • By default, the outbound method supported is **Webhook Notification Plugin**.<br>• Select Instance: Select the configured instance for the Webhook plug-in.<br>• Create New Instance: You can also create a new outbound instance for the Webhook plug-in type. For details, see Add a Webhook Notification Plugin for Outbound Instance. |

7. Click **Next**.

8. Select the payload template.

| Option | Description |
|---|---|
| Payload Template | Select the Webhook payload template that you want to include in the notification. There is a Default WLP Action Webhook Template and you can select the default template if no customization is required. You can also customize your payload for a Webhook Notification Plugin. For details on creating payload templates, see Creating Payload Templates for Outbound Plugins. |

9. Click **Next** to test the notification
10. In the **Test Notification** tab, click **Initiate Process** to initiate the notification configuration validation process.
11. If you activate the **Filter the objects based on criteria outlined in the Define Criteria section** option, then the objects displayed below are based on the criteria outlined in the **Define Criteria** section.
12. Select an object for validation.
13. Click **Validate Configuration**.
    - Notification Validation Steps: View the steps involved in validating the notification configuration. The steps also indicate an error, if any. The validation steps differ based on the selected Outbound method.

| Outbound Method | Validation Steps |
|---|---|
| Webhook Notification Plugin | • Validate Criteria<br>• Establish Endpoint Connection<br>• Certificates<br>• Authentication<br>• Send Notification<br>• Endpoint Receives Notification |

    - Response: The Response tab in the right pane displays if the test passed successfully or if there were any errors.
    - Body: Displays the content of the notification.
14. Click **Create** to create the notification rule. You can view the rule you created under **Alerts** > **Notifications**.

## Outbound Settings in VCF Operations

You use the Outbound Settings to manage your communication settings so that you can send information to users or applications outside of VCF Operations.

You manage your outbound options from this page, including adding or editing outbound plug-ins, and turning the configured plug-ins on or off. When activated, the plug-in sends a message to users as email notifications, or sends a message to other applications.

Outbound plug-in settings determine how the supported external notification systems connect to their target systems. You configure one or more instances of one or more plug-in types so that you can send data about generated notifications outside of VCF Operations.

You configure each plug-in with the required information, including destination locations, hosts, ports, user names, passwords, instance name, or other information that is required to send notifications to those target systems. The target systems can include email recipients, log files, or other management products.

Some plug-ins are included with VCF Operations, and others might be added when you add a management pack as a solution.

The configuration options vary depending on which plug-in you select from the **Plug-In Type** drop-down menu.

To add outbound notification plug-in, see Adding Outbound Notification Plug-Ins in VCF Operations.

## Where You Find Outbound Settings

To manage your outbound settings, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.

| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your Outbound Plug-Ins.<br>• Add. Opens the Outbound Plug-In dialog box where you configure the connection options for the instance.<br>Select an existing plugin and click the vertical ellipsis to perform the following actions.<br>• Edit. Modify the Outbound Plug-In instance details.<br>• Delete. Removes the selected plug-in instance.<br>• Activate or Deactivate. Starts or stops the plug-in instance. Deactivating an instance allows you to stop sending the messages configured for the plug-in without removing the configuration from your environment.<br>• Export. Downloads the outbound settings.<br>• Import. Allows you to import outbound settings. To import:<br>– Click the **Import** option from the horizontal ellipsis.<br>– Click **Browse** and select the file to import.<br>– Select if you want to Overwrite or Skip the file in case of a conflict.<br>– Click **Import** to import outbound settings, and click **Done**. |
| Instance Name | Name that you assigned when you created the plug-in instance. Click the vertical ellipsis to perform the following actions.<br>• Edit. Allows you to edit the selected payload template.<br>• Delete. Removes the selected payload template.<br>• Activate or Deactivate. Starts or stops the plug-in instance. Deactivating an instance allows you to stop sending the messages configured for the plug-in without removing the configuration from your environment.<br>• Export. Downloads the outbound settings. |
| Plug-In Type | Type of configured plug-in for the plug-in instance. The types of plug-ins vary depending on the solutions you have added to your environment.<br>The most common plug-in types include standard email, SNMP trap, and log file. |
| Status | Specifies whether the plug-in is currently running. |

## List of Outbound Plugins

VCF Operations provides outbound plug-ins. This list includes the name of the plug-in and whether you can filter the outbound data based on your notification settings.

If the plug-in supports configuring notification rules, then you can filter the messages before they are sent to the target system. If the plug-in does not support notifications, all messages are sent to the target system, and you can process them in that application.

If you installed other solutions that include other plug-in options, they appear as a plug-in option with the other plug-ins.

Messages and alerts are sent only when the plug-in is activated.

**Table 1211: Notification Support for Outbound plug-ins**

| Outbound plug-in | Configure Notification Rules |
|---|---|
| Log File plug-in | Yes<br>To filter the log file alerts, you can either configure the file named `TextFilter.xml` or configure the notification rules. |
| Standard Email plug-in | Yes |
| SNMP Trap plug-in | Yes |
| Webhook Notification Plugin | Yes |
| Slack plug-in | Yes |
| Service-Now Notification plug-in | Yes |

## Configuring HTTP Proxy for Outbound Settings

You can configure an HTTP proxy for outbound communication over HTTP/HTTPS protocol in VCF Operations. Once the HTTP proxy is configured for an outbound setting, all the corresponding outbound HTTP(S) communication must happen through that proxy.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile. Click the **HTTP Proxy for Outbound Settings** tab.
2. Click **Add**.

**Table 1212: HTTP Proxy Options**

| Options | Description |
|---|---|
| Proxy Name | Name of the HTTP proxy server. |
| Proxy Host/ IP | The IP address of the HTTP proxy. |
| Proxy Port | Port number used to connect to the HTTP proxy server. |
| Proxy Username | Username of the HTTP proxy server. |
| Proxy Password | Password for the HTTP proxy server username. |

3. Click **Save**.
   The HTTP proxy setting is added.

## Importing and Exporting HTTP Proxy for Outbound Settings

You can import or export the HTTP Proxy settings for outbound plugins.

### Importing HTTP Proxy for Outbound Settings

1. From the **HTTP Proxy for Outbound Settings** tab, click the horizontal ellipsis, and then click **Import** to import the outbound proxy settings.
2. Click **Browse** to select the outbound proxy setting and enter the **Encryption Key**.
3. In case of a conflict, click **Overwrite HTTP Proxy for Outbound Settings** to delete the existing proxy setting and proceed. Optionally, click **Skip HTTP Proxy for Outbound Settings** to cancel the import.

   **Note:**
   A conflict happens when you try to import a proxy with a name that already exists in the proxy list. Proxy names are unique and cannot be repeated.
4. Click **Import**.

The HTTP proxy import process begins.

**Exporting HTTP Proxy for Outbound Settings**

1. From the **HTTP Proxy for Outbound Settings** tab, select the HTTP Proxy you want to export, click the horizontal ellipsis, and then click **Export**.
2. Enter a new password in the **Setup a new password to export data** field.
3. Re-enter the password in the **Repeat a password** field.
4. Click **Export**.

The outbound proxy settings data gets exported in the `.json` format. The passphrase entered at the time of export is used to encrypt the sensitive information. The same passphrase must be used at the time of import.

## Adding Outbound Notification Plug-Ins in VCF Operations

You add outbound plug-in instances so that you can notify users about alerts or capture alert data outside of VCF Operations.

You can configure one or more instances of the same plug-in type if you need to direct alert information to multiple target systems.

### Add a Standard Email Plug-In for VCF Operations Outbound Alerts

You add a Standard Email Plug-In so that you can use Simple Mail Transfer Protocol (SMTP) to email VCF Operations alert notifications to your virtual infrastructure administrators, network operations engineers, and other interested individuals.
Ensure that you have an email user account that you can use as the connection account for the alert notifications. If you choose to require authentication, you must also know the password for this account.

1. In the VCF Operations navigation bar at the top, click **Home** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
2. Click **Add**, and from the **Plug-In Type** drop-down menu, select **Standard Email Plugin**.
   The dialog box expands to include your SMTP settings.
3. Enter an **Instance Name**.
   This is the name that identifies this instance that you select when you later configure notification rules.
4. Configure the SMTP options appropriate for your environment.

| Option | Description |
|---|---|
| **Use Secure Connection** | Activates secure communication encryption using SSL/TLS. If you select this option, you must select a method in the **Secure Connection Type** drop-down menu.<br>**Note:**<br>In VCF Operations, the Standard Email Plugin always uses the 'starttls' command when you select the **Use Secure Connection** checkbox and select **TLS** as the **Secure Connection Type**. |
| **Requires Authentication** | Activates authentication on the email user account that you use to configure this SMTP instance. If you select this option, you must provide a password for the user account. |
| **SMTP Host** | URL or IP address of your email host server. |
| **SMTP Port** | Default port SMTP uses to connect with the server. |
| **Secure Connection Type** | Select either SSL/TLS as the communication encryption method used in your environment from the drop-down menu. You must select a connection type if you select Use Secure Connection.<br>**Note:**<br>In VCF Operations, the Standard Email Plugin always uses the 'starttls' command when you select the **Use Secure Connection** checkbox and select **TLS** as the **Secure Connection Type**. |

| Option | Description |
|---|---|
| **Sender Email Address** | Email address that appears on the notification message. |
| **Sender Name** | Displayed name for the sender email address. |
| **Credential Type** | Select the **Credential Type** from the list. If your Endpoint URL does not need any authentication, then select **No Credential** from the **Credential Type** list.<br>You can select **Basic Authentication** or **OAuth Authentication**. |
| **Credential** | Add or edit the **Credential** details. Click the plus icon to enter the details of the new credentials in the **Create New Credential** pane, and click **Save**.<br>This field appears only when you select **Basic Authentication** or **OAuth Authentication** as the **Credential Type**.<br>**Basic Authentication**<br>Enter the Name, User Name, and Password.<br>**OAuth Authentication**<br>Enter the following details:<br>• Name: Enter a name for the authentication.<br>• Grant Type: Select either **Client Credentials** or **Password Credentials**.<br>• Authentication URL: Enter the URL from where the access token can be retrieved.<br>• Client ID: Enter the client ID for the authentication URL.<br>• Client Secret: Enter the client secret for the authentication URL.<br>• User Name: Enter the user name for the authentication URL.<br>**Note:**<br>This field appears only when the grant type is **Password Credentials**.<br>• Password: Enter the password for the authentication URL.<br>**Note:**<br>This field appears only when the grant type is **Password Credentials**.<br>• Scope: Enter the labels to specify the access token. The labels specify the permissions that the access tokens will have.<br>• Send Credentials: Select either **In auth header** or **In body**.<br>– In authauthorization header: Sends the Client ID and Client Secret in the header.<br>– In body: Sends the Client ID and Client Secret in the payload body.<br>**Note:**<br>This field appears only when the grant type is **Client Credentials**.<br>• Access Token Path: Enter your access token path.<br>• Validity Token Path: To keep track of when the token is going to expire, enter the validity token path and select the format from the drop-down list. You can choose one of the following formats:<br>• Second<br>• Milisecond<br>• Absolute Time |

| Option | Description |
| --- | --- |
| | • Header Name: Enter a header name. By default, the header name is 'Authorization'.<br>• Prefix: Enter a prefix. By default, the prefix is 'Bearer'.<br>• HTTP Proxy: Select your HTTP Proxy.<br><br>**Note:**<br><br>Starting VCF Operations 8.14, you could only view, add, modify, or delete credentials that you created or were assigned to you. You could view unassigned credentials only if you had the required permissions. When you upgrade to VCF Operations 8.16.1, you can deactivate the **Credential Ownership Enforcement** option from Global Settings to be able to modify credentials created and owned by others. For more information, see List of Global Settings. |
| **Receiver Email Address** | Receiver's email address. |

5. Click **Save**.
6. To start the outbound alert service for this plug-in, select the instance in the list and click **Activate** on the toolbar.

This instance of the Standard Email Plug-In for outbound SMTP alerts is configured and running.

Create notification rules that use the Standard Email Plug-In to send a message to your users about alerts requiring their attention.

## Add a Log File Plug-In for VCF Operations Outbound Alerts

You add a Log File plug-in when you want to configure VCF Operations to log alerts to a file on each of your nodes. If you installed VCF Operations as a multiple node cluster, each node processes and logs the alerts for the objects that it monitors. Each node logs the alerts for the objects it processes.

Ensure that you have write access to the file system path on the target nodes.

All alerts are added to the log file. You can use other applications to filter and manage the logs.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
2. Click **Add**, and from the **Plug-In Type** drop-down menu, select **Log File**.
   The dialog box expands to include your log file settings.
3. In the **Alert Output Folder** text box, enter the folder name.
   If the folder does not exist in the target location, the plug-in creates the folder in the target location. The default target location is: `/usr/lib/vmware-vcops/common/bin/`.
4. Click **Save**.
5. To start the outbound alert service for this plug-in, select the instance in the list and click **Activate** on the toolbar.

This instance of the log file plug-in is configured and running.

When the plug-in is started, the alerts are logged in the file. Verify that the log files are created in the target directory as the alerts are generated, updated, or canceled.

**Sample Log File Plug-In Output**
Here is a sample log file plug-in output.

## Add an SNMP Trap Plug-In for VCF Operations Outbound Alerts

You add an SNMP Trap plug-in when you want to configure VCF Operations to log alerts on an existing SNMP Trap server in your environment.

Ensure that you have an SNMP Trap server configured in your environment, and that you know the IP address or host name, port number, and community that it uses.

You can provide filtering when you define a Notification using an SNMP Trap destination.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
2. Click **Add**, and from the **Plug-In Type** drop-down menu, select **SNMP Trap Plugin**.
   The dialog box expands to include your SNMP trap settings.
3. Enter an **Instance Name**.
4. Configure the SNMP trap settings appropriate to your environment.

| Option | Description |
|---|---|
| **Destination Host** | IP address or fully qualified domain name of the SNMP management system to which you are sending alerts. |
| **Port** | Port used to connect to the SNMP management system. Default port is 162. |
| **Community** | Text string that allows access to the statistics. SNMP Community strings are used only by devices that support SNMPv1 and SNMPv2c protocol. |
| **Username** | User name to configure SNMP trap settings in your environment. If the user name is specified, SNMPv3 is considered as the protocol by the plugin.<br>If left blank, SNMPv2c is considered as the protocol by the plugin.<br>**Note:**<br>SNMP uses User Datagram Protocol (UDP) as its transport protocol. |
| **Authentication Protocol** | Authentication algorithms available are SHA-224, SHA-256, SHA-384, SHA-512. |
| **Authentication Password** | Authentication password. |
| **Privacy Protocol** | Privacy algorithms available are AES192, AES256. |
| **Privacy Password** | Privacy password. |
| **Engine ID** | Engine ID serves as an identifier for the agent. It is used with a hashing function to generate localized keys for authentication and encryption of SNMP v3 messages.<br>It is mandatory to specify the Engine ID when configuring the SNMP Trap plugin. If you do not add the Engine ID and save the SNMP Trap plugin instance, the field is auto-generated the next time you edit the settings. |
| **Varbinds Encoding** | Varbinds Encoding allows you to define character encoding when SNMP notifications are sent in languages other than English. Character encoding is used to convert textual data to binary format. The receiving endpoint decodes the received binary data into text accordingly.<br>By default, the encoding is set to ISO-8859-1. You can select the following encoding option from the list.<br>• UTF-8 |

| Option | Description |
| --- | --- |
| | **Note:**<br>The newly added encoding option will be effective only when the SNMP servers receiving the notifications support the encoding. |

5. Click **Test** to validate the connection.

   **Note:**
   The Community and Username options are mutually exclusive. Define either one of them to avoid an error. If you add a user name, you can optionally define the Authentication Protocol and Authentication Password followed by the Privacy Protocol and Privacy Password. The privacy protocol and its password cannot be defined independent of the authentication protocol and its password.

This instance of the SNMP Trap plug-in is configured and running.

When the plug-in is added, configure notifications for receiving the SNMP traps. For more information, see Creating Notification Rules for Alerts.

### Add a Service-Now Notification Plug-In for Outbound Alerts

You add a Service-Now Notification plug-in when you want to integrate Service Now ticketing system with VCF Operations. Service Now creates an incident whenever an alert is triggered in VCF Operations.

Ensure that you have log in credentials for Service-Now.

Ensure that you are assigned with IT Infrastructure Library (ITIL) role in Service Now.

Using Service-Now Notification Plug-In you can send alert notifications to the Service Now ticketing system to create incidents. The incident includes information like the Caller, Category, Subcategory, Business Service, and other attributes related to alerts.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
2. Click **Add** and from the **Plug-In Type** drop-down menu, select **Service-Now Notification Plug-in**.
   The dialog box expands to include your plug-in instance settings.
3. Enter an **Instance Name**.
4. Enter the Service Now URL.
   `https://dev22418.service-now.com/`
5. Enter a value for the Connection Count.
   The connection count represents the maximum number of open connections allowed per node in VCF Operations.
6. Optional: Select your **HTTP Proxy**.
7. Select the **Credential Type** from the list.

   **Note:**
   If your Endpoint URL does not need any authentication, then select **No Credential** from the **Credential Type** list.
8. Add or edit the **Credential** details. Click the plus icon to enter the details of the new credentials in the **Create New Credential** pane, and click **Save**. This field appears only when you select **Basic Authentication** as the **Credential Type**.

   **Note:**
   When you upgrade to the latest version of VCF Operations, all credentials get unassigned. The VCF Operations administrator must assign the credentials from the **Orphan and Unassigned** page. For more information, see the topic, Managing Orphaned and Unassigned Content.

9. To verify the specified paths, credentials, and permissions, click **Test**.
10. Click **Save**.

This instance of the Service-Now Notifications plug-in is configured and running.

When the plug-in is added, configure notifications for creating incidents in the Service-Now ticketing system. For more information, see Creating Notification Rules for Alerts.

### Notifications - Add a Slack Plugin for Outbound Notifications

You can add a Slack plug-in to forward alerts and configure multiple notification rules with different slack channels. The Slack plug-in allows you to receive pre-formatted alert details with alert fields and helps you run VCF Operations using alert links to troubleshoot further.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
2. Click **Add** and from the **Plugin Type** drop-down menu, select **Slack Plugin**.
   The dialog box expands to include your plug-in instance settings.
3. Enter an **Instance Name**.
4. Enter a value for the **Connection Count**.
   The connection count represents the maximum number of open connections allowed per node in VCF Operations.
5. Optional: Select your **HTTP Proxy**.
6. To verify the specified paths, credentials, and permissions, click **Test**.
7. Click **Save**.

This instance of the Slack plugin is configured and running.

When the plugin is added, configure notifications for different slack channels. For more information, see Creating Notification Rules for Alerts.

### Add a Webhook Notification Plugin for Outbound Instance

You can integrate Webhook with any endpoint REST API and configure outbound payload.

Ensure that you have login credentials for Webhook.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
2. Click **Add** and from the **Plugin Type** drop-down menu, select **Webhook Notification Plugin**.
   The dialog box expands to include your plugin instance settings.
3. Enter an **Instance Name**.
4. Enter the Webhook URL.

   **Note:**
   For notifications that reference webhook outbound instances, the URL that you enter here serves as a base URL that is combined with the endpoint URL suffix defined in related webhook payload templates.
5. Enter a value for the **Connection Count**.
   The connection count represents the maximum number of open connections allowed per node in VCF Operations.

6. Optional: Select your **HTTP Proxy**.
7. Select the **Credential Type** from the list.

   **Note:**
   If your Endpoint URL does not need any authentication, then select **No Credential** from the **Credential Type** list.
8. Add or edit the **Credential** details. Click the plus icon and enter the details of the new credentials in the right pane, and click **Save**.

   **Note:**
   When you upgrade to the latest version of VCF Operations, all credentials get unassigned. The VCF Operations administrator must assign the credentials from the **Orphan and Unassigned** page. For more information, see the topic, Managing Orphaned and Unassigned Content.

   The fields in the **Create New Credential** pane appear based on the **Credential Type** you select.

| Credential Type | Fields |
|---|---|
| Basic Authentication | Enter the Name, User Name, and Password. |
| Bearer Token | Enter the Name of the credential and the Token. |
| OAuth Authentication | Enter the following details:<br>• Name: Enter a name for the authentication.<br>• Grant Type: Select either **Client Credentials** or **Password Credentials**.<br>• Authentication URL: Enter the URL from where the access token can be retrieved.<br>• Client ID: Enter the client ID for the authentication URL.<br>• Client Secret: Enter the client secret for the authentication URL.<br>• User Name: Enter the user name for the authentication URL.<br>**Note:** This field appears only when the grant type is **Password Credentials**.<br>• Password: Enter the password for the authentication URL.<br>**Note:** This field appears only when the grant type is **Password Credentials**.<br>• Scope: Enter the labels to specify the access token. The labels specify the permissions that the access tokens will have.<br>• Send Credentials: Select either **In auth header** or **In body**.<br>– In auth header: Sends the Client ID and Client Secret in the header.<br>– In body: Sends the Client ID and Client Secret in the payload body.<br>**Note:** This field appears only when the grant type is **Client Credentials**.<br>• Access Token Path: Enter your access token path.<br>• Validity Token Path: To keep track of when the token is going to expire, enter the validity token path and select the format from the drop-down list. You can choose one of the following formats:<br>– Second<br>– Milisecond<br>– Absolute Time<br>• Header Name: Enter a header name. By default, the header name is 'Authorization'.<br>• Prefix: Enter a prefix. By default, the prefix is 'Bearer'.<br>• HTTP Proxy: Select your HTTP Proxy. |
| Certificate | Enter the following details:<br>• Name: Enter the name of the certificate.<br>• Certificate: Enter the certificate in the X.509 format.<br>• Certificate Key: Enter the private key. The formats supported are Open SSL, PKCS1, and PKCS8 |

| Credential Type | Fields |
|---|---|
| API Key | Enter the Name, API Key, and the API Value. |

9. To verify the specified paths, credentials, and permissions, click **Test**.

   **Note:**

   - The **Test** feature does not currently support the Custom Templates. If the template contains a custom headers, the test might fail.

10. Click **Save**.

This instance of the Webhook Notification plugin is configured and running.

### Sample Email Alert

Here is a sample email for a newly created alert.

```
Alert Definition Name: Node is experiencing swapping due to memory pressure
Alert Definition Description: Node is experiencing swapping due to memory pressure
Object Name : VMware Aria Operations Node-VMwareAria Cluster Node
Object Type : vC-Ops-Node
Alert Impact: risk
Alert State : warning
Alert Type : Application
Alert Sub-Type : Performance
Object Health State: info
Object Risk State: warning
Object Efficiency State: info
Control State: Open
Symptoms:
SYMPTOM SET - self
```

| Symptom Name | Object Name | Object ID | Metric | Message Info |
|---|---|---|---|---|
| Node swap usage at Warning level | VCF Operations Node-VMware Aria Cluster Node | 50ec874a-2d7d-4e78-98b1-afb26fd67e58 | Swap\|Workload | 59.183 > 30.0 |

```

## Exporting and Importing Outbound Settings

As a VCF Operations admin, you can backup the content before upgrading, export all the outbound plugin configurations, and import it into a different VCF Operations instance. You can also export the content from VCF Operations on-prem to VCF Operations.

**Note:**
Any user with "Manage" Outbound Settings permission can export and import outbound plugin configurations.

1. Export an outbound setting.
   a) In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
   b) Select the outbound settings that you want to export and click the horizontal ellipses and select **Export**.
   c) Setup a new password to export data. The password should be at least 14 characters long.
   d) Click **Export**.

      The outbound setting data is exported in the .json format. A password is used to encrypt the data in the file using the AES algorithm with a 128-bit key. Use the same password while importing this file.
2. Import an outbound setting.

   **Note:**
   Before importing the outbound setting, ensure that you have exported the outbound plugin configurations.
   a) In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Outbound Settings** tile.
   b) Click the horizontal ellipses and select **Import**.
   c) Click **Browse** to select the `.json` file and enter the password that you had set while exporting the content.
   d) If there is a conflict while importing the content, you can either overwrite the existing outbound settings or skip the import, which is the default.
   e) Click **Import** to import outbound settings to the destination setup.

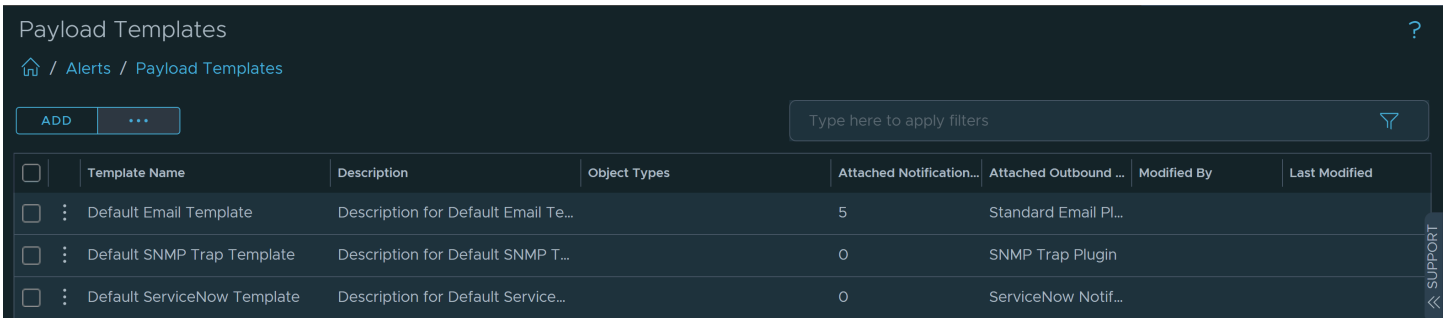
   **Note:**
   While importing outbound settings on VCF Operations, Cloud Proxy configurations will be excluded.

## Payload Templates in VCF Operations

Payload is an essential information in the data block that you send or receive from the server. Use the **Payload Templates** page to view the list of payload templates available for each plug-in in VCF Operations. You can add, manage, and edit your payload templates from this page. Default payload templates are provided for each plug-in type.

## Where You Find Payload Templates

To manage your payload templates, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Payload Templates** tile.



| Option | Description |
|---|---|
| Toolbar options | Use the toolbar options to manage your notification rules.<br>• Add. Use the Create Payload Template dialog box to create new payload templates.<br>Click the horizontal ellipsis to perform the following actions.<br>• Delete. Removes the selected payload template.<br>• Export. Downloads the payload template.<br>**Note:**<br>Export and delete actions are not supported for the default payload templates available for each plug-in.<br>• Import. Allows you to import payload templates. To import:<br>– Click the **Import** option from the horizontal ellipsis.<br>– Click **Browse** and select the file to import.<br>– Select if you want to Overwrite or Skip the import in case of a conflict.<br>– Click **Import** to import the payload template, and then click **Done**. A message with the number of imported and skipped files will appear. |
| Quick Filter | Limits the list based on the text you type. It considers only text from templates Name column.<br>You can also sort columns in the data grid. You can view a blue arrow next to the column according to which sorting was performed, pointing up or down based on the sorting order (ascending or descending). |
| Template Name | Name of the payload template.<br>Click the vertical ellipsis to perform the following actions.<br>• Edit. Allows you to edit the selected payload template.<br>• Clone. Clones the selected payload template.<br>• Delete. Removes the selected payload template.<br>• Export. Downloads the payload template.<br>•<br>**Note:**<br>Edit, Delete, and Export actions are not supported for the default payload templates available for each plug-in. |
| Description | Description of the payload template. |
| Object Types | Base object type against which the payload template is defined, if any. |
| Attached Notification Rules | Notification rule attached to the payload template. |
| Attached Outbound Methods | Outbound plugin type attached to the payload template. |
| Modified By | Name of the last person to modify the payload template. |
| Last Modified | Date on which the payload template was last modified. |

## Creating Payload Templates for Outbound Plugins

You can create a payload template for an outbound plugin of your choice in VCF Operations.

Use payload templates to configure the payload of an email, and customize the subject line, and email body. You can enable your own input properties and different payloads for updated and canceled alerts.

You can customize payloads only for Standard Email Plug-in and Webhook Notification Plug-in.

1. In the VCF Operations navigation bar at the top, click **Operations** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Payload Templates** tile. On the toolbar, click **Add** to create a new payload template.
2. In the **Details** tab, enter the basic details of the payload template.

| Option | Description |
|---|---|
| Name | Provide a name for the payload template. |
| Description | Enter a description for the payload template. |
| Outbound Method | Outbound plugin for which you want to create a new payload template.<br>Select one of the outbound alert plug-in types: Log File Plugin, Standard Email Plugin, SNMP Trap Plugin, Webhook Notification Plugin, Slack Plugin, and Service-Now Notification Plugin. |
| Advanced Settings | |
| Notification Type | • Select **Alert** to configure an alert notification.<br>• Select **Action** to configure notification for WLP VM movement task.<br>**Note:**<br>The **Action** option appears only when you select **Webhook Notification Plugin** in the **Outbound Method** field. You can configure notification for type 'Action' only for the Webhook Notification Plugin. |

3. Click **Next**.
4. In the **Object Content** tab, define the object details that you want to include in the notifications.

   **Note:**
   To create a payload template, it is mandatory to add the object type for all the outbound plugin types except for the Standard Email Plugin and Webhook Notification Plugin.

| Option | Description |
|---|---|
| Add Object Type | • Select an object type from the list. Once you select the object type, define self metrics/properties, ancestors, descendants, ancestor metrics/properties, and descendant metrics/properties associated with the object type that you want to include in the notification.<br>From the right pane, double-click or drag the metrics and properties into the **Add Metrics and Properties** box. You can select up to 30 metrics and properties.<br>**Note:**<br>For Action Type of Notifications, only Virtual Machine is available for selection.<br>• Define the ancestor/descendant object type along with the corresponding metrics and properties.<br>Select the **ancestor/descendant** from the drop-down menu and from the right pane, double-click or drag the corresponding metrics and properties into the left pane.<br>**Note:**<br>For SNMP Trap Plugin, you can only select ancestor objects but you cannot add metrics/properties or define descendant details.<br>The information that you define here will be included in the alert notification for all the plug-ins. However, for a Webhook Notification Plugin and Standard Email Plugin, the information will be included only when you define the values in the **Payload Details** tab. |

5. Click **Create** to create the new payload template or click **Next** if you are creating a payload template for a Standard Email Plugin or a Webhook Notification Plugin.
6. In the **Payload Details** tab, enter the payload details that you want to include in the notification.

   **Note:**
   This tab is available only when you are creating a payload template for a Standard Email Plugin or a Webhook Notification Plugin.

| Option | Description |
|---|---|
| Do you want to add template input properties? | Select **Yes** to add input properties and enter the **Key**, **Type**, **Display Name**, and **Description** of the input property. Otherwise, select **No**.<br>**Note:**<br>The input properties are specific to your endpoint. Once you define the input properties in the template, you must provide the appropriate values in each rule where this template will be used. |
| Do you want different payload details for new, updated, and canceled alerts? | Select **Yes** to define different payload details for new, updated, and canceled alerts. Otherwise, select **No**.<br>**Note:**<br>This field does not appear when the **Notification Type** is **Action**. |
| The following fields appear while creating a payload template for the Standard Email Plugin. | |
| Subject | Enter a subject for the email notification. |
| Body | Enter the content for the email notification. You can also search for parameters in the right pane. Click the copy icon next to the parameter to copy the parameter and you can paste the parameter in the email body.<br>You can use the options in the toolbar to edit, format, and highlight the email content.<br>**Note:**<br>You can set up different email content for new, updated, and canceled alerts. |
| The following fields appear while creating a payload template for the Webhook Notification Plugin. | |
| Endpoint URL | Enter the endpoint URL. The endpoint URL will be appended to the base URL provided in the related webhook outbound instance.<br>**Note:**<br>The entire URL is encoded. However, there is an exception to use the character '/' in the URL. |
| Content Type | Select the content type for the payload. |
| Custom Headers | Enter the **HTTP Custom Header Name** and **Value**. Click the plus icon to add multiple custom headers.<br>**Note:**<br>For webhook payloads using token-based authentication, add an Authorization Header in the format required by the endpoint. |
| HTTP Method | Select the HTTP method of request. |

| Option | Description |
|---|---|
| Payload of the request | Payload for the selected plug-in type. It displays information based on the selected metrics, properties, ancestors, and object types. You can search for parameters in the right pane. Click the copy icon next to the parameter to copy the parameter and you can paste the parameter in the **Payload of the request** box. |

7. Click **Create**.

   Once the payload template is created, you can view it in the **Payload Templates** page. After selecting a payload template in the notification rule, you can view the payload template details in the **Notifications** page.

# Managing Alert Groups in VCF Operations

For easy and better management of alerts, you can arrange them as a group as per your requirement.

It is complicated to identify a problem in large environments as you receive different kind of alerts. To manage alerts easily, group them by their definitions.

For example, there are 1000 alerts in your system. To identify different types of alerts, group them based on their alert definitions. It is also easy to detect the alert having the highest severity in the group.

When you group alerts, you can view the number of times the alerts with the same alert definition are triggered. By grouping alerts, you can perform the following tasks easily and quickly:

- Find the noisiest alert: The alert that has triggered maximum number of times is known as the noisiest alert. Once you find it, you can deactivate it to avoid further noise.
- Filter alerts: You can filter alerts based on a substring in alert definitions. The result shows the group of alerts that contain the substring.

**Note:**

- If you cancel or deactivate an alert group, the alerts are not canceled instantly. It might take some time if the group is large.
- Only one group can be expanded at a time.
- The number next to the group denotes the number of alerts in that particular group.
- The criticality

  sign
  indicates the highest level of severity of an alert in a group.

## Grouping Alerts in VCF Operations

You can group alerts by time, criticality, definition, and object type.

To group alerts:

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Alerts**.
2. Select from the various options available from the **Group By** drop-down menu.

## Deactivating Alerts in VCF Operations

In an alerts group, you can deactivate an alert by a single click.

To deactivate an alert:

1. In the VVCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Alerts**.
2. From the **Group By** drop-down, select **Definition**, and click on the name of the Alert Definition Group.
3. From the data grid, click **Actions** > **Deactivate**.

   You can deactivate the alerts by two methods:

   - Deactivate Alert in All Policies: Deactivates the alert for all the objects for all the policies.

- Deactivate Alert in Selected Policies: Deactivates the alert for the objects having the selected policy.

## Alert Definition Best Practices

As you create alert definitions for your environment, apply consistent best practices so that you optimize alert behavior for your monitored objects.

### Alert Definitions Naming and Description

The alert definition name is the short name that appears in the following places:

- In data grids when alerts are generated
- In outbound alert notifications, including the email notifications that are sent when outbound alerts and notifications are configured in your environment

Ensure that you provide an informative name that clearly states the reported problem. Your users can evaluate alerts based on the alert definition name.

The alert definition description is the text that appears in the alert definition details and the outbound alerts. Ensure that you provide a useful description that helps your users understand the problem that generated the alert.

### Wait and Cancel Cycle

The wait cycle setting helps you adjust for sensitivity in your environment. The wait cycle for the alert definition goes into effect after the wait cycle for the symptom definition results in a triggered symptom. In most alert definitions you configure the sensitivity at the symptom level and configure the wait cycle of alert definition to 1. This configuration ensures that the alert is immediately generated after all of the symptoms are triggered at the desired symptom sensitivity level.

The cancel cycle setting helps you adjust for sensitivity in your environment. The cancel cycle for the alert definition goes into affect after the cancel cycle for the symptom definition results in a cancelled symptom. In most definitions you configure the sensitivity at the symptom level and configure the cancel cycle of alert definition to 1. This configuration ensures that the alert is immediately cancelled after all of the symptoms conditions disappear after the desired symptom cancel cycle.

### Create Alert Definitions to Generate the Fewest Alerts

You can control the size of your alert list and make it easier to manage. When an alert is about a general problem that can be triggered on a large number of objects, configure its definition so that the alert is generated on a higher level object in the hierarchy rather than on individual objects.

As you add symptoms to your alert definition, do not overcrowd a single alert definition with secondary symptoms. Keep the combination of symptoms as simple and straightforward as possible.

You can also use a series of symptom definitions to describe incremental levels of concern. For example, `Volume nearing capacity limit` might have a severity value of Warning while `Volume reached capacity limit` might have a severity level of Critical. The first symptom is not an immediate threat, but the second one is an immediate threat. You can then include the Warning and Critical symptom definitions in a single alert definition with an Any condition and set the alert criticality to be Symptom Based. These settings cause the alert to be generated with the right criticality if either of the symptoms is triggered.

### Avoid Overlapping and Gaps Between Alerts

Overlaps result in two or more alerts being generated for the same underlying condition. Gaps occur when an unresolved alert with lower severity is canceled, but a related alert with a higher severity cannot be triggered.

A gap occurs in a situation where the value is <=50% in one alert definition and >=75% in a second alert definition. The gap occurs because when the percentage of volumes with high use falls between 50 percent and 75 percent, the first problem cancels but the second does not generate an alert. This situation is problematic because no alert definitions are active to cover the gap.

**Actionable Recommendations**

If you provide text instructions to your users that help them resolve a problem identified by an alert definition, precisely describe how the engineer or administrator should fix the problem to resolve the alert.

To support the instructions, add a link to a wiki, runbook, or other sources of information, and add actions that you run from VCF Operations on the target systems.

## Create a Simple Alert Definition

While troubleshooting, you can now quickly create an alert for a particular object type or a metric in a quick and efficient way.

You can create a simple alert definition from the following locations.

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Workbench** and select the metric for which you want to create an alert. You can create an alert from the **Potential Evidence** or the **Metrics** tab.
- In the VCF Operations navigation bar at the top, click **Observe** and in the left navigation pane, click **Alerts**. Select an alert and click the **Potential Evidence** tab.
- From the Home page, you can search for the specific object type or metric in the search bar.

1. Click the drop-down menu available in the right side of the widget and select the **Create an Alert Definition** option.

   **Note:**
   You cannot create alert definitions for Badge, Time, and Capacity Remaining metrics.

2. In the Create Alert Definition page, enter the **Name** and **Description** of the alert.
3. Set thresholds, criticality, and the number of wait cycles. Click **Show Advanced Settings** to set Wait Cycle and Cancel Cycle.

   **Note:**
   The Object Type or Metric/Property are pre-selected and cannot be edited.

4. Click **Create**.

   The new alert is created and the policy the object belongs to and its children policies are activated for the alert.

## Create a New Alert Definition

Based on the root cause of the problem, and the solutions that you used to fix the problem, you can create a new alert definition for VCF Operations to alert you. When the alert is triggered on your host system, VCF Operations alerts you and provides recommendations on how to solve the problem.

To alert you before your host systems experience critical capacity problems, and have VCF Operations notify you of problems in advance, you create alert definitions, and add symptom definitions to the alert definition.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Alert Definitions** tile.
2. Enter `capacity` in the search text box.

   Review the available list of capacity alert definitions. If a capacity alert definition does not exist for host systems, you can create one.

3. Click **Add** to create a capacity alert definition for your host systems.
   a) In the alert definition workspace, for the Name and Description, enter `Hosts - Alert on Capacity Exceeded`.
   b) For the Base Object Type, select **vCenter Adapter > Host System**
   c) Under **Advanced Settings**, select the following options.

| Option | Selection |
|---|---|
| Impact | Select **Risk**. |
| Criticality | Select **Immediate**. |
| Alert Type and Subtype | Select **Application : Capacity**. |
| Wait Cycle | Select **1**. |
| Cancel Cycle | Select **1**. |

   d) In the **Symptoms/Conditions** workspace, select the following options.

| Option | Selection |
|---|---|
| Defined On | Select **Self**. |
| Symptom Definition Type | Select **Metric / Property**. |
| Quick filter (Name) | Enter `capacity`. |

   e) From the Symptom Definition list, click **Host System Capacity Remaining is moderately low** and drag it to the left pane.

      In the Symptoms pane, make sure that the Base object exhibits criteria is set to **All** by default.
   f) For Add Recommendations, enter `virtual machine` in the quick filter text box.
   g) Click **Review the symptoms listed and remove the number of vCPUs from the virtual machine as recommended by the system**, and drag it to the recommendations area in the left pane.

      This recommendation is set to Priority 1.
4. Click **Save** to save the alert definition.

   Your new alert appears in the list of alert definitions.

You have added an alert definition to have VCF Operations alert you when the capacity of your host systems begins to run out.

## Create a Log Based Alert Definition

Use this example to create a log based alert definition. Log based alerts are new in VCF 9.0.

For more information on log symptoms, see Log Symptoms.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Alert Definitions** tile.
2. Click **Add** to create a new log alert definition for your host systems. For example, create an alert definition for Cluster Performance - Failed vMotions.
   a) In the alert definition workspace, for the Name, enter `Cluster Performance - Failed vMotions`.
   b) For the Base Object Type, select **Host System**.
3. Click **NEXT**.
4. In the **Symptoms/Conditions** step, do the following.
   a) Drag and drop **Add Log Condition**.
   b) Select **Cluster Performance - Failed vMotions** from the **Filter By** drop-down list.
   c) Change the time period to six hours.
5. Click **NEXT**. Do not add any recommendation. Click **NEXT** again.
6. In the **Policies** step, select the default policy.
7. Click **CREATE**.

In the Alert Definitions table, sort by the last modified column to view the newly created Log based alert definition.

> **Note:**
>
> Some and log-based alert definitions may contain expressions that cannot be converted into the VCF Operations UI-supported format. Attempting to interpret or partially render these queries may lead to incorrect behavior or confusion.
>
> Some complex saved queries and log-based alert definitions may not appear in the UI due to parsing limitations. These items are skipped when their expressions cannot be converted into the VCF Operations UI-supported format.

# Create an Alert Definition for Department Objects

As a virtual infrastructure administrator, you are responsible for the virtual machines and hosts that the accounting department uses. You can create alerts to manage the accounting department objects.

You received several complaints from your users about delays when they are using their accounting applications. Using VCF Operations, you identified the problem as related to CPU allocations and workloads. To better manage the problem, you create an alert definition with tighter symptom parameters so that you can track the alerts and identify problems before your users encounter further problems.

Using this scenario, you create a monitoring system that monitors your accounting objects and provides timely notifications when problems occur.

## Add Description and Base Object to Alert Definition

To create an alert to monitor the CPUs for the accounting department virtual machines and monitor host memory for the hosts on which they operate, you begin by describing the alert.

When you name the alert definition and define alert impact information, you specify how the information about the alert appears in VCF Operations. The base object is the object around which the alert definition is created. The symptoms can be for the base object and for related objects.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Alert Definitions** tile.
2. Click **Add** to add a definition.
3. Type a name and description.

   In this scenario, type `Acct VM CPU early warning` as the alert name, which is a quick overview of the problem. The description, which is a detailed overview, should provide information that is as useful as possible. When the alert is generated, this name and description appears in the alert list and in the notification.

4. From the **Base Object Type** drop-down menu, expand **vCenter Adapter** and select **Host System**.

   This alert is based on host systems because you want an alert that acts as an early warning to possible CPU stress on the virtual machines used in the accounting department. By using host systems as the based object type, you can respond to the alert symptom for the virtual machines with bulk actions rather than responding to an alert for each virtual machine.

5. Click **Advanced Settings** and configure the metadata for this alert definition.
   a) From the **Impact** drop-down menu, select **Risk**.

      This alert indicates a potential problem and requires attention in the near future.
   b) From the **Criticality** drop-down menu, select **Immediate**.

      As a Risk alert, which is indicative of a future problem, you still want to give it a high criticality so that it is ranked for correct processing. Because it is designed as an early warning, this configuration provides a built-in buffer that makes it an immediate risk rather than a critical risk.
   c) From the **Alert Type and Subtype** drop-down menu, select **Performance** under **Virtualization/Hypervisor**.
   d) To ensure that the alert is generated during the first collection cycle after the symptoms become true, set the **Wait Cycle** to `1`.
   e) To ensure that the an alert is removed as soon as the symptoms are no longer triggered, set the **Cancel Cycle** to `1`.

      The alert is canceled in the next collection cycle if the symptoms are no long true.

   These alert impact options help you identify and prioritize alerts as they are generated.

You started an alert definition where you provided the name and description, selected host system as the base object type, and defined the data that appears when the alert generated.

Continue in the workspace, adding symptoms to your alert definition. See Add a Virtual Machine CPU Usage Symptom to the Alert Definition.

## Add a Virtual Machine CPU Usage Symptom to the Alert Definition

To generate alerts related to CPU usage on your accounting virtual machines, you add symptoms to your VCF Operations alert definition after you provide the basic descriptive information for the alert. The first symptom you add is related to CPU usage on virtual machines. You later use a policy and group to apply alert to the accounting virtual machines.

Begin configuring the alert definition. See Add Description and Base Object to Alert Definition.

This scenario has two symptoms, one for the accounting virtual machines and one to monitor the hosts on which the virtual machines operate.

1. In the **Alert Definition Workspace** window, after you configure the **Name and Description**, **Base Object Type**, and **Alert Impact**, click **Next** and configure the symptoms.
2. Begin configuring the symptom set related to virtual machines CPU usage.
   a) From the **Select Symptom** drop-down menu, select **Metric / Property**.
   b) From the **Defined On** drop-down menu, select **Child**.
   c) From the **Filter by Object Type** drop-down menu, select **Virtual Machine**.
   d) Click **Create New** to open the **Add Symptom Definition** workspace window.
3. Configure the virtual machine CPU usage symptom in the **Add Symptom Definition** workspace window.
   a) From the **Base Object Type** drop-down menu, expand **vCenter Adapter** and select **Virtual Machine**.

      The collected metrics for virtual machines appears in the list.
   b) In the metrics list **Search** text box, which searches the metric names, type `usage`.
   c) In the list, expand **CPU** and drag **Usage (%)** to the workspace on the left.
   d) From the threshold drop-down menu, select **Dynamic Threshold**.

      Dynamic thresholds use VCF Operations analytics to identify the trend metric values for objects.

e) In the **Symptom Definition Name** text box, type a name similar to `VM CPU Usage above trend`.
f) From the criticality drop-down menu, select **Warning**.
g) From the threshold drop-down menu, select **Above Threshold**.
h) Leave the **Wait Cycle** and **Cancel Cycle** at the default values of 3.

This Wait Cycle setting requires the symptom condition to be true for 3 collection cycles before the symptom is triggered. This wait avoids triggering the symptom when there is a short spike in CPU usage.

i) Click **Save**.

The dynamic symptom, which identifies when the usage is above the tracked trend, is added to the symptom list.

4. In the **Alert Definition Workspace** window, drag **VM CPU Usage above trend** from the symptom definition list to the symptom workspace on the left.

   The Child-Virtual Machine symptom set is added to the symptom workspace.

5. In the symptoms set, configure the triggering condition so that when the symptom is true on half of the virtual machines in the group to which this alert definition is applied, the symptom set is true.
   a) From the value operator drop-down menu, select **>**.
   b) In the value text box, enter `50`.
   c) From the value type drop-down menu, select **Percent**.

You defined the first symptom set for the alert definition.

Add the host memory usage symptom to the alert definition. See Add a Host Memory Usage Symptom to the Alert Definition.

## Add a Host Memory Usage Symptom to the Alert Definition

To generate alerts related to CPU usage on your accounting virtual machines, you add a second symptom to your VCF Operations alert definition after you add the first symptom. The second symptom is related to host memory usage for the hosts on which the accounting virtual machines operate.

Add the virtual machine CPU usage symptom. See Add a Virtual Machine CPU Usage Symptom to the Alert Definition.

1. In the **Alert Definition Workspace** window, after you configure the **Name and Description**, **Base Object Type**, and **Alert Impact**, click **Next**.
2. Configure the symptom related to host systems for the virtual machines.
   a) From the **Select Symptom** drop-down menu, select **Metric / Property**.
   b) From the **Defined On** drop-down menu, select **Self**.
   c) Click **Create New** to add new symptom.
3. Configure the host system symptom in the **Add Symptom Definition** workspace window.
   a) From the **Base Object Type** drop-down menu, expand **vCenter Adapters** and select **Host System**.
   b) In the metrics list, expand **Memory** and drag **Usage (%)** to the workspace on the left.
   c) From the threshold drop-down menu, select **Dynamic Threshold**.

      Dynamic thresholds use VCF Operations analytics to identify the trend metric values for objects.

   d) In the **Symptom Definition Name** text box, enter a name similar to `Host memory usage above trend`.
   e) From the criticality drop-down menu, select **Warning**.
   f) From the threshold drop-down menu, select **Above Threshold**.
   g) Leave the **Wait Cycle** and **Cancel Cycle** at the default values of 3.

      This Wait Cycle setting requires the symptom condition to be true for three collection cycles before the symptom is triggered. This wait avoids triggering the symptom when a short spike occurs in host memory usage.

   h) Click **Save**.

   The dynamic symptom identifies when the hosts on which the accounting virtual machines run are operating above the tracked trend for memory usage.

   The dynamic symptom is added to the symptom list.

4. In the **Alert Definition Workspace** window, drag **Host memory usage above trend** from the symptoms list to the symptom workspace on the left.

   The Self-Host System symptom set is added to the symptom workspace.

5. On the Self-Host System symptom set, from the value type drop-down menu for **This Symptom set is true when**, select **Any**.

   With this configuration, when any of the hosts running accounting virtual machines exhibit memory usage that is above the analyzed trend, the symptom condition is true.

6. At the top of the symptom set list, from the **Match {operator} of the following symptoms** drop-down menu, select **Any**.

   With this configuration, if either of the two symptom sets, virtual machine CPU usage or the host memory, are triggered, an alert is generated for the host.

You defined the second symptom set for the alert definition and configured how the two symptom sets are evaluated to determine when the alert is generated.

Add recommendations to your alert definition so that you and your engineers know how to resolve the alert when it is generated. See Add Recommendations to the Alert Definition.

## Add Recommendations to the Alert Definition

To resolve a generated alert for the accounting department's virtual machines, you provide recommendations so that you or other engineers have the information you need to resolve the alert before your users encounter performance problems.

Add symptoms to your alert definition. See Add a Host Memory Usage Symptom to the Alert Definition.

As part of the alert definition, you add recommendations that include actions that you run from VCF Operations and instructions for making changes in vCenter that resolve the generated alert.

1. In the **Alert Definition Workspace** window, after you configure the **Name and Description**, **Base Object Type**, **Alert Impact**, and **Add Symptom Definitions**, click **Next** and add the recommended actions and instructions.
2. Click **Create New Recommendation** and select an action recommendation to resolve the virtual machine alerts.
   a) In the **Description** text box, enter a description of the action similar to `Add CPUs to virtual machines.`
   b) From the **Actions** drop-down menu, select **Set CPU Count for VM**.
   c) Click **Create**.
3. Click **Create New Recommendation** and provide an instructive recommendation to resolve host memory problems similar to this example.
   ```
   If this host is part of a DRS cluster, check the DRS settings to verify that the load balancing setting are configured correctly. If necessary, manually vMotion the virtual machines.
   ```
4. Click **Create**.
5. Click **Create New Recommendation** and provide an instructive recommendation to resolve host memory alerts.
   a) Enter a description of the recommendation similar to this example.
   ```
   If this is a standalone host, add more memory to the host.
   ```

b) To make the URL a hyperlink in the instructions, copy the URL to your clipboard.
c) Highlight the text in the text box and click the hyperlink icon.
d) Paste the URL in the **Create a hyperlink** text box and click **OK**.
e) Click **Create**.

6. In the **Alert Recommendation Workspace**, drag **Add CPUs to virtual machines**, **If this host is part of a DRS cluster**, and the **If this is a standalone host** recommendations from the list to the recommendation workspace in the order presented.
7. Click **Next** to select policies and view notifications.
8. Click **Create**.

You provided the recommended actions and instructions to resolve the alert when it is generated. One of the recommendations resolves the virtual machine CPU usage problem and the other resolves the host memory problem.

Create a group of objects to use to manage your accounting objects. See Create a Custom Accounting Department Group.

## Create a Custom Accounting Department Group

To manage, monitor, and apply policies to the accounting objects as a group, you create a custom object group.

Verify that you completed the alert definition for this scenario. See Add Recommendations to the Alert Definition.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Custom Groups** tile under Logical Groupings.
2. Click **Add** to create a new custom group.
3. Type a name similar to `Accounting VMs and Hosts`.
4. From the **Group Type** drop-down menu, select **Department**.
5. From the **Policy** drop-down menu, select **Default Policy**.
   When you create a policy, you apply the new policy to the accounting group.
6. In the Define membership criteria area, from the **Select the Object Type that matches the following criteria** drop-down menu, expand **vCenter Adapter**, select **Host System**, and configure the dynamic group criteria.
   a) From the criteria drop-down menu, select **Relationship**.
   b) From the relationships options drop-down menu, select **Parent of**.
   c) From the operator drop-down menu, select **contains**.
   d) In the **Object name** text box, enter `acct`.
   e) From the navigation tree drop-down list, select **vSphere Hosts and Clusters**.
   You created a dynamic group where host objects that are the host for virtual machines with acct in the virtual machine name are included in the group. If a virtual machine with acct in the object name is added or moved to a host, the host object is added to the group.
7. Click **Preview** in the lower-left corner of the workspace, and verify that the hosts on which your virtual machines that include acct in the object name appear in the **Preview Group** window.
8. Click **Close**.
9. Click **Add another criteria set**.
   A new criteria set is added with the OR operator between the two criteria sets.

10. From the **Select the Object Type that matches the following criteria** drop-down menu, expand **vCenter Adapter**, select **Virtual Machine**, and configure the dynamic group criteria.
    a) From the criteria drop-down menu, select **Properties**.
    b) From the **Pick a property** drop-down menu, expand **Configuration** and double-click **Name**.
    c) From the operator drop-down menu, select **contains**.
    d) In the **Property value** text box, enter `acct`.

    You created a dynamic group where virtual machine objects with acct in the object name are included in the group that depends on the presence of those virtual machines. If a virtual machine with acct in the name is added to your environment, it is added to the group.
11. Click **Preview** in the lower-left corner of the workspace, and verify that the virtual machines with acct in the object name are added to the list that also includes the host systems.
12. Click **Close**.
13. Click **OK**.

    The Accounting VMs and Hosts group is added to the Groups list.

You created a dynamic object group that changes as virtual machines with acct in their names are added, removed, and moved in your environment.

Create a policy that determines how VCF Operations uses the alert definition to monitor your environment. See Create a Policy for the Accounting Alert.

## Create a Policy for the Accounting Alert

To configure how VCF Operations evaluates the accounting alert definition in your environment, you configure a policy that determines behavior so that you can apply the policy to an object group. The policy limits the application of the alert definition to only the members of the selected object group.

- Verify that you completed the alert definition for this scenario. See Add Recommendations to the Alert Definition.
- Verify that you created a group of objects that you use to manage you accounting objects. See Create a Custom Accounting Department Group.

When an alert definition is created, it is added to the default policy and activated, ensuring that any alert definitions that you create are active in your environment. This alert definition is intended to meet the needs of the accounting department, so you deactivate it in the default policy and create a new policy to govern how the alert definition is evaluated in your environment, including which accounting virtual machines and related hosts to monitor.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definitions** tile.
2. Click **Add**.
3. Type a name similar to `Accounting Objects Alerts Policy` and provide a useful description similar to the following example.

   ```
   This policy is configured to generate alerts when
   Accounting VMs and Hosts group objects are above trended
    CPU or memory usage.
   ```
4. Select **Default Policy** from the **Start with** drop-down menu.
5. On the left, click **Customize Alert / Symptom Definitions** and deactivate all the alert definitions except the new Acct VM CPU early warning alert.
   a) In the Alert Definitions area, click **Actions** and select **Select All**.

      The alerts on the current page are selected.
   b) Click **Actions** and select **Deactivate**.

      The alerts indicate Deactivated in the State column.

c) Repeat the process on each page of the alerts list.
d) Select **Acct VM CPU early warning** in the list, click **Actions** and select **Activate**.
The Acct VM CPU early warning alert is now activated.

6. On the left, click **Apply Policy to Groups** and select **Accounting VMs and Hosts**.
7. Click **Save**.

You created a policy where the accounting alert definition exists in a custom policy that is applied only to the virtual machines and hosts for the accounting department.

Create an email notification so that you learn about alerts even you when you are not actively monitoring VCF Operations. See Configure Notifications for the Department Alert.

## Configure Notifications for the Department Alert

To receive an email notification when the accounting alert is generated, rather than relying on your ability to generally monitor the accounting department objects in VCF Operations, you create notification rules.

- Verify that you completed the alert definition for this scenario. See Add Recommendations to the Alert Definition.
- Verify that standard email outbound alerts are configured in your system. See Add a Standard Email Plug-In for VCF Operations Outbound Alerts.

Creating an email notification when accounting alerts are triggered is an optional process, but it provides you with the alert even when you are not currently working in VCF Operations.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Notifications** tile.
2. Click **Add** to add a notification rule.
3. Configure the communication options.
   a) In the **Name** text box, type a name similar to `Acct Dept VMs or Hosts Alerts`.
   b) From the **Select Plug-In Type** drop-down menu, select **StandardEmailPlugin**.
   c) From the **Select Instance** drop-down menu, select the standard email instance that is configured to send messages.
   d) In the **Recipient(s)** text box, type your email address and the addresses of other recipients responsible for the accounting department alerts. Use a semicolon between recipients.
   e) Leave the **Notify again** text box blank.
   If you do not provide a value, the email notice is sent only once. This alert is a Risk alert and is intended as an early warning rather than requiring an immediate response.
   You configured the name of the notification when it is sent to you and the method that is used to send the message.
4. In the Filtering Criteria area, configure the accounting alert notification trigger.
   a) From the **Notification Trigger** drop-down menu, select **Alert Definition**.
   b) Click **Select Alert Definitions**.
   c) Select **Acct VM CPU early warning** and click **Select**.
5. Click **Save**.

You created a notification rule that sends you and your designated engineers an email message when this alert is generated for your accounting department alert definition.

Create a dashboard with alert-related widgets so that you can monitor alerts for the accounting object group. See Create a Dashboard to Monitor Department Objects.

## Create a Dashboard to Monitor Department Objects

To monitor all the alerts related to the accounting department object group, you create a dashboard that includes the alert list and other widgets. The dashboard provides the alert data in a single location for all related objects.

Create an object group for the accounting department virtual machines and related objects. See Create a Custom Accounting Department Group.

Creating a dashboard to monitor the accounting virtual machines and related hosts is an optional process, but it provides you with a focused view of the accounting object group alerts and objects.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Dashboards** and then click **Create**.
2. In the Dashboard Configuration definition area, type a tab name similar to `Accounting VMs and Hosts` and configure the layout options.
3. Click **Widget List** and drag the following widgets to the workspace.
   - **Alert List**
   - **Efficiency**
   - **Health**
   - **Risk**
   - **Top Alerts**
   - **Alert Volume**

   The blank widgets are added to the workspace. To change the order in which they appear, you can drag them to a different location in the workspace.
4. On the Alert List widget title bar, click **Edit Widget** and configure the settings.
   a) In the **Title** text box, change the title to `Acct Dept Alert List`.
   b) For the **Refresh Content** option, select **On**.
   c) Type `Accounting` in the **Search** text box and click **Search**.
      The Accounting value corresponds to the name of the object group for the accounting department virtual machines and related hosts.
   d) In the filtered resource list, select the **Accounting VMs and Hosts** group.
      The Accounting VMs and Hosts group is identified in the Selected Resource text box.
   e) Click **OK**.

   The Acct Dept Alert List is now configured to display alerts for the Accounting VMs and Hosts group objects.
5. Click **Widget Interactions** and configure the following interactions.
   a) For Acct Dept Alert List, leave the selected resources blank.
   b) For Top Alerts, Health, Risk, Efficiency, and Alert Volume select **Acct Dept Alert List** from the **Selected Resources** drop-down menu.
   c) Click **Apply Interactions**.

   With the widget interaction configured in this way, the select alert in the Acct Dept Alert List is the source for the data in the other widgets. When you select an alert in the alert list, the Health, Risk, and Efficiency widgets display alerts for that object, Top Alerts displays the topic issues affecting the health of the object, and Alert Volume displays an alert trend chart.
6. Click **Save**.

You created a dashboard that displays the alerts related to the accounting virtual machines and hosts group, including the Risk alert you created.

## Monitoring and Responding to Alerts

Alerts indicate a problem in your environment. Alerts are generated when the collected data for an object is compared to alert definitions for that object type and the defined symptoms are true. When an alert is generated, you are presented with the triggering symptoms, so that you can evaluate the object in your environment, and with recommendations for how to resolve the alert.

Alerts notify you when an object or group of objects are exhibiting symptoms that are unfavorable for your environment. By monitoring and responding to alerts, you stay aware of problems and can react to them in a timely fashion.

Generated alerts drive the status of the top-level badges, Health, Risk, and Efficiency.

In addition to responding to alerts, you can generally respond to the status of badges for objects in your environment.

You can take ownership of an alert or assign alerts to other VCF Operations users.

## Monitoring Alerts in VCF Operations

You can monitor your environment for generated alerts in several areas in VCF Operations. The alerts are generated when the symptoms in the alert definition are triggered, letting you know when the objects in your environment are not operating within the parameters you defined as acceptable.

Generated alerts appear in many areas of VCF Operations so that you can monitor and respond to problems in your environment.

### Alerts

Alerts are classified as Health, Risk, or Efficiency. Health alerts indicate problems that require immediate attention. Risk alerts indicate problems that must be addressed shortly, before the problems become immediate health problems. Efficiency alerts indicate areas where you can reclaim wasted space or improve the performance of objects in your environment.

You can monitor the alerts for your environment in the following locations.

- Alerts
- Health
- Risk
- Efficiency

You can monitor alerts for a selected object in the following locations.

- Alert Details, including the **Summary**, **Timeline**, and **Metric Charts** tabs
- **Summary** tab
- **Alerts** tab
- **Events** tab
- Custom dashboards
- Alert notifications

### Working with Alerts

Alerts indicate a problem that must be resolved so that triggering conditions no longer exist and the alert is canceled. Suggested resolutions are provided as recommendations so that you can approach the problem with solutions.

As you monitor alerts, you can take ownership, suspend, or manually cancel alerts.

When you cancel an alert, the alert and any symptoms of type message event, or metric event are canceled. You cannot manually cancel other types of symptoms. If a message event symptom or metric event symptom triggered the event, then the symptom is no longer triggered. If a metric symptom or property symptom triggered the alert, a new alert might be created for the same conditions in the next few minutes.

The correct way to remove an alert is to address the underlying conditions that triggered the symptoms and generated the alert.

### Migrated Alerts

If you migrated alerts from a previous version of VCF Operations, the alerts are listed in the overview with a canceled status, but alert details are not available.

# Actions in VCF Operations

Actions are the ability to update objects or read data about objects in monitored systems, and are commonly provided in VCF Operations as part of a solution. The actions added by solutions are available from the object Actions menu, list and view menus, including some dashboard widgets, and can be added to alert definition recommendations.

The possible actions include read actions and update actions.

The read actions retrieve data from the target objects.

The update actions modifies the target objects. For example, you can configure an alert definition to notify you when a virtual machine is experiencing memory issues. Add an action in the recommendations that runs the Set Memory for Virtual Machine action. This action increases the memory and resolves the likely cause of the alert.

To see or use the actions for your vCenter objects, you must activate actions in the vCenter Adapter for each monitored vCenter instance. Actions can only be viewed and accessed if you have the required permissions.

## Actions, Modified Objects, and Object Levels in VCF Operations Actions

The list of actions includes the name of the action, the objects that each one modifies, and the object levels at which you can run the action. You use this information to ensure that you correctly apply the actions as alert recommendations and when the actions are available in the **Actions** menu.

**Actions and Modified Objects**

VCF Operations actions make changes to objects in your managed vCenter instances.

When you grant a user access to actions in VCF Operations, that user can take the granted action on any object that VCF Operations manages.

**Action Object Levels**

The actions are available when you work with different object levels, but they modify only the specified object. If you are working at the cluster level and select **Power On VM**, all the virtual machines in the cluster for which you have access permission are available for you to run the action. If you are working at the virtual machine level, only the selected virtual machine is available.

| Action | Modified Object | Object Levels |
|---|---|---|
| Rebalance Container | Virtual Machines | • Data Center<br>• Custom Data Center |
| Delete Idle VM | Virtual Machines | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Set DRS Automation | Cluster | • Clusters |
| Move VM | Virtual Machine | • Virtual Machines |
| Power Off VM | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Shut Down Guest OS for VM | Virtual Machine<br>VMware Tools must be installed and running on the target virtual machines to run this action. | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Power On VM | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Delete Powered Off VM | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Set Memory for VM<br>and<br>Set Memory for VM Power Off Allowed | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Set Memory Resources for VM | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |

| Action | Modified Object | Object Levels |
|---|---|---|
| Set CPU Count for VM<br>and<br>Set CPU Count for VM Power Off Allowed | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Set CPU Resources for VM | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Set CPU Count and Memory for VM<br>and<br>Set CPU Count and Memory for VM Power Off Allowed | Virtual Machine | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Delete Unused Snapshots for VM | Snapshot | • Clusters<br>• Host Systems<br>• Virtual Machines |
| Delete Unused Snapshots for Datastore | Snapshot | • Clusters<br>• Datastores<br>• Host Systems |
| Execute Script | Virtual Machine | • Virtual Machine |
| Get Top Processes | Virtual Machine | • Virtual Machine |
| Apply Guest User Mapping | vCenter Server | • vCenter Server<br>**Note:**<br>This action is deprecated and will be removed in the next release. |
| Clear Guest User Mapping | vCenter Server | • vCenter Server<br>**Note:**<br>This action is deprecated and will be removed in the next release. |
| Export Guest User Mapping | vCenter Server | • vCenter Server<br>**Note:**<br>This action is deprecated and will be removed in the next release. |
| Configure Included Services | Service Discovery Adapter Instance | • Service Discovery Adapter Instance<br>**Note:**<br>This action is deprecated and will be removed in the next release. |

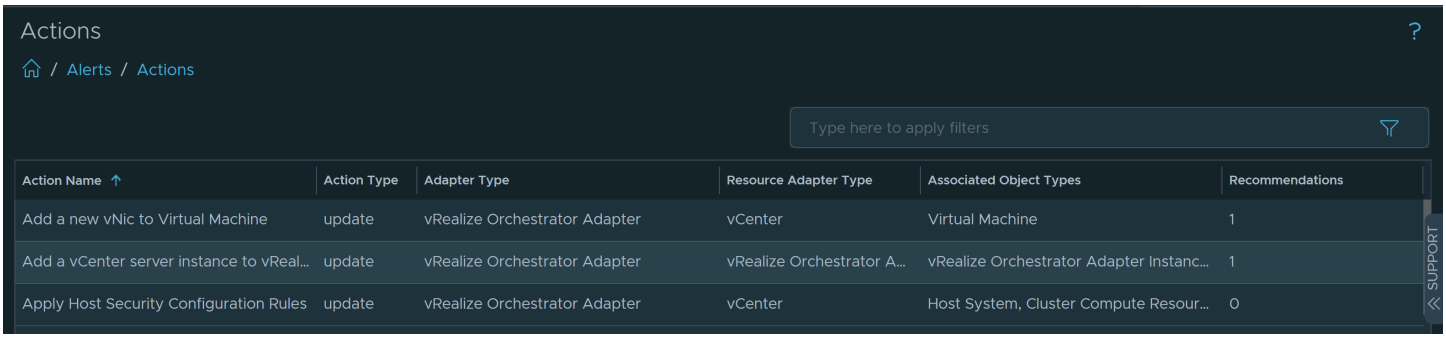
## Viewing Actions List in VCF Operations

Actions are the method you use to configuration changes on managed objects that you initiate from VCF Operations. These actions are available to add to alert recommendations.

Actions are defined to run on the target object from different object levels, allowing you to add actions as recommendations for alert definitions that are configured for different base objects. The Actions page is a list of actions available in your environment.

### Where You Find the Actions List

To view the available actions, in the VCF Operations navigation bar at the top, click **Operation** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Actions** tile.



| Option | Description |
|---|---|
| Filter options | Limits the list based on the text you type.<br>You can also sort on the columns in the data grid. |
| Action Name | Name of the action. Duplicate names indicate that the action name is provided by more than one adapter or has more than one associated object.<br>Click this link to view Details page. On the Details Page, you can click on Recommendations to view the associated recommendations. |
| Action Type | Type of action that the action performs, either read or update.<br>• Update actions make changes to the target objects.<br>• Read actions retrieve data from the target objects. |
| Adapter Type | Name of the configured adapter that provides the action. |
| Resource Adapter Type | Adapter that provides the action. |
| Associated Object Types | Indicates the object level at which the action instance runs. |
| Recommendations | Indicates whether the action is used in at least one recommendation. |

The actions `Delete Unused Snapshots for Datastore Express` and `Delete Unused Snapshots for VM Express` appear. However, these actions can only be run in the user interface from an alert whose first recommendation is associated with this action. You can use the REST API to run these actions.

The following actions are also not visible except in the alert recommendations:

- `Set Memory for VM Power Off Allowed`
- `Set CPU Count for VM Power Off Allowed`
- `Set CPU Count and Memory for VM Power Off Allowed`

These actions are intended to be used to automate the actions with the `Power Off Allowed` flag set to true.

## Actions Supported for Automation

Recommendations can identify ways to remediate problems indicated by an alert. Some of these remediations can be associated with actions defined in your VCF Operations instance. You can automate several of these remediation actions for an alert when that recommendation is the first priority for that alert.

You activate actionable alerts in your policies. By default, automation is deactivated in policies. To configure automation for your policy, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Policy Definition** tile. Then, to edit a policy, access the **Alert / Symptom Definitions** workspace, and select **Local** for the **Automate** setting in the Alert / Symptom Definitions pane.

When an action is automated, you can use the **Automated** and **Alert** columns in **Recent Tasks** under **Administration** > **Control Panel** to identify the automated action and view the results of the action.

- VCF Operations uses the **automationAdmin** user account to trigger automated actions. For these automated actions that are triggered by alerts, the Submitted By column displays the **automationAdmin** user.
- The Alert column displays the alert that triggered the action. When an alert is triggered that is associated to the recommendation, it triggers the action without any user intervention.

The following actions are supported for automation:

- Delete Powered Off VM
- Delete Idle VM
- Move VM
- Power Off VM
- Power On VM
- Set CPU Count And Memory for VM
- Set CPU Count And Memory for VM Power Off Allowed
- Set CPU Count for VM
- Set CPU Count for VM Power Off Allowed
- Set CPU Resources for VM
- Set Memory for VM
- Set Memory for VM Power Off Allowed
- Set Memory Resources for VM
- Shut Down Guest OS for VM

#### Roles Needed to Automate Actions

To automate actions, your role must have the following permissions:

- Create, edit, and import policies in **Administration** > **Configurations** > **Policy Definition**.
- Create, clone, edit, and import alert definitions in **Administartion** > **Configurations** > **Alert Definitions**.
- Create, edit, and import recommendation definitions in **Administration** > **Configurations** > **Recommendations**.

> **Important:**
> You set the permissions used to run the actions separately from the alert and recommendation definition. Anyone who can modify alerts, recommendations, and policies can also automate the action, even if they do not have permission to run the action.

For example, if you do not have access to the Power Off VM action, but you can create and modify alerts and recommendations, you can see the Power Off VM action and assign it to an alert recommendation. Then, if you automate the action in your policy, VCF Operations uses the `automationAdmin` user to run the action.

#### Example Action Supported for Automation

For the Alert Definition named `Virtual machine has chronic high CPU workload leading to CPU stress`, you can automate the action named `Set CPU Count for VM`.

When CPU stress on your virtual machines exceeds a critical, immediate, or warning level, the alert triggers the recommended action without user intervention.

## Integration of Actions with VCF Automation

VCF Operations restricts actions on data centers and custom data centers that contains VCF Automation managed child objects such as, cluster compute resources, hosts, and VMs.

You can turn on or turn off the actions on VCF Automation managed objects by modifying the **Operational Actions** from the respective vCenter in Cloud Accounts or by creating a new role with limited action ability on VCF Automation managed objects.

### Actions Determine Whether Objects Are Managed

Actions check the objects in the VCF Automation managed resource container to determine which objects are being managed by VCF Automation.

Actions such as Rebalance Container check the child objects of the data center container or custom data center container to determine whether the objects are managed by VCF Automation. If the objects are being managed, the action does not appear on those objects.

## Working with Actions That Use Power Off Allowed

Some of the actions provided with VCF Operations require the virtual machines to shut down or power off, depending on the configuration of the target machines, to run the actions. You should understand the impact of the Power Off Allowed option before running the actions so that you select the best options for your target virtual machines.

### Power Off and Shut Down

The actions that you can run on your vCenter instances include actions that shut down virtual machines and actions that power off virtual machines. It also includes actions where the virtual machine must be in a powered off state to complete the action. Whether the VM is shut down or powered off depends on how it is configured and what options you select when you run the action.

The shut-down action shuts down the guest operating system and then powers off the virtual machine. To shut down a virtual machine from VCF Operations, the VMware Tools must be installed and running on the target objects.

The power off action turns off the VM without regard for the state of the guest operating system. In this case, if the VM is running applications, your user might lose data. After the action is finished, for example, modifying the CPU count, the virtual machine is returned to the power state it was in when the action began.

### Power Off Allowed and VMware Tools

For the actions where you are increasing the CPU count or the amount of memory on a VM, some operating systems support the actions if the Hot Plug is configured on the VM. For other operating systems, the virtual machine must be in a powered off state to change the configuration. To accommodate this need where the VMware Tools is not running, the Set CPU Count, Set Memory, and Set CPU Count and Memory actions include the Power Off Allowed option.

If you select Power Off Allowed, and the machine is running, the action verifies whether VMware Tools is installed and running.

- If VMware Tools is installed and running, the virtual machine is shut down before completing the action.
- If VMware Tools is not running or not installed, the virtual machine is powered off without regard for the state of the operating system.

If you do not select Power Off Allowed and you are decreasing the CPU count or memory, or the hot plug is not activated for increasing the CPU count or memory, the action does not run and the failure is reported in Recent Tasks.

### Power Off Allowed When Changing CPU Count or Memory

When you run the actions that change the CPU count and the amount of memory, you must consider several factors to determine if you want to use the Power Off Allowed option. These factors include whether you are increasing or decreasing the CPU or memory and whether the target virtual machines are powered on. If you increase the CPU or memory values, whether hot plug is activated also affects how you apply the option when you run the action.

How you use Power Off Allowed when you are decreasing the CPU count or the amount of memory depends on the power state of the target virtual machines.

**Table 1213: Decreasing CPU Count and Memory Behavior Based On Options**

| Virtual Machine Power State | Power Off Allowed Selected | Results |
|---|---|---|
| On | Yes | If VMware Tools is installed and running, the action shuts down the virtual machine, decreases the CPU or memory, and powers the machine back on.<br>If VMware Tools is not installed, the action powers off the virtual machine, decreases the CPU or memory, and powers the machine back on. |
| On | No | The action does not run on the virtual machine. |
| Off | Not applicable. The virtual machine is powered off. | The action decreases the value and leaves the virtual machine in a powered off state. |

How you use Power Off Allowed when you are increasing the CPU count or the amount of memory depends on several factors, including the state of the target virtual machine and whether hot plug is activated. Use the following information to determine which scenario applies to your target objects.

If you are increasing the CPU count, you must consider the power state of the virtual machine and whether CPU Hot Plug is activated when determining whether to apply Power Off Allowed.

**Table 1214: Increasing CPU Count Behavior.**

| Virtual Machine Power State | CPU Hot Plug Activated | Power Off Allowed Selected | Results |
|---|---|---|---|
| On | Yes | No | The action increases the CPU count to the specified amount. |
| On | No | Yes | If VMware Tools is installed and running, the action shuts down the virtual machine, increases the CPU count, and powers the machine back on.<br>If VMware Tools is not installed, the action powers off the virtual machine, increases the CPU count, and powers the machine back on. |
| Off | Not applicable. The virtual machine is powered off. | Not required. | The action increases the CPU count to the specified amount. |

If you are increasing the memory, you must consider the power state of the virtual machine, whether Memory Hot Plug is activated, and whether there is a Hot Memory Limit when determining how to apply Power Off Allowed.

**Table 1215: Increasing Memory Amount Behavior**

| Virtual Machine Power State | Memory Hot Plug Activated | Hot Memory Limit | Power Off Allowed Selected | Results |
|---|---|---|---|---|
| On | Yes | New memory value = hot memory limit | No | The action increases the memory the specified amount. |
| On | Yes | New memory value > hot memory limit | Yes | If VMware Tools is installed and running, the action shuts down the virtual machine, increases the memory, and powers the machine back on.<br>If VMware Tools is not installed, the action powers off the virtual machine, increases the memory, and powers the machine back on. |
| On | No | Not applicable. The hot plug is not activated. | Yes | If VMware Tools is installed and running, the action shuts down the virtual machine, increases the memory, and powers the machine back on.<br>If VMware Tools is not installed, the action powers off the virtual machine, increases the memory, and powers the machine back on. |
| Off | Not applicable. The virtual machine is powered off. | Not applicable. | Not required | The action increases the memory the specified amount. |

## Running Actions from VCF Operations

The actions available in VCF Operations allow you to modify the state or configuration of selected objects in vCenter from VCF Operations. For example, you might need to modify the configuration of an object to address a problematic resource issue or to redistribute resources to optimize your virtual infrastructure.

The most common use of the actions is to solve problems. You can run them as part of your troubleshooting procedures or add them as a resolution recommendation for alerts.

When you grant a user access to actions in VCF Operations, that user can take the granted action on any object that VCF Operations manages.

When you are troubleshooting problems, you can run the actions from the center pane Actions menu. Alternatively, you can run them from the toolbar on list views that contain the supported objects.

When an alert is triggered, and you determine that the suggested action is the most likely way to resolve the problem, you can run the action on one or more objects.

## Run Actions from Toolbars in VCF Operations

When you run actions in VCF Operations, you change the state of vCenter objects. You run one or more actions when you encounter objects where the configuration or state of the object is affecting your environment. These actions allow you to reclaim wasted space, adjust memory, or conserve resources.

- Verify that the vCenter Adapter is configured to run actions for each vCenter instance. See Configure a vCenter Serve Cloud Account in *VCF Operations Configuration Guide.* .
- Verify that the vCenter Adapter is configured to run actions for each vCenter instance. See the *VCF Operations Configuration Guide.* .
- Ensure that you understand how to use the power-off-allowed option if you are running Set CPU Count, Set Memory, and Set CPU Count and Memory actions. See Working with Actions That Use Power Off Allowed section in *VCF Operations Configuration Guide.* .
- Ensure that you understand how to use the power-off-allowed option if you are running Set CPU Count, Set Memory, and Set CPU Count and Memory actions. See the section Working With Actions That Use Power Off Allowed in the VCF Operations Information Center.

This procedure for running actions is based on the VCF Operations**Actions** menus and is commonly used when you are troubleshooting problems. The available actions depend on the type of objects with which you are working. You can also run actions as alert recommendations.

1. Select the object in the Inventory page inventory tree or select one or more objects it in a list view.
2. Click **Actions** on the main toolbar or in an embedded view.
3. Select one of the actions.

   If you are working with a virtual machine, only the virtual machine is included in the dialog box. If you are working with clusters, hosts, or datastores, the dialog box that appears includes all objects.
4. To run the action on the object, select the check box and click **OK**.

   The action runs and a dialog box appears that displays the task ID.
5. To view the status of the job and verify that the job finished, click **Recent Tasks** or click **OK** to close the dialog box.

   The Recent Tasks list appears, which includes the task you just started.

**Rebalance Container Action**
When the workload in your environment becomes imbalanced, you can move the workload across your objects to rebalance the overall workload. The container for the rebalance action can be a data center or a custom data center, and the objects that are moved are the virtual machines in the suggested list provided by the action.

### DRS Must be Activated on Clusters

Your vCenter instance must have a cluster that passes a DRS-activated check for the Rebalance Container action to appear in the Actions drop-down menu.

To get the Rebalance Container action from a custom data center or data center, and the related alerts, you must have the following:

- A vCenter Adapter configured with the actions activated for each vCenter instance
- A vCenter instance with at least one cluster that is DRS-activated.

If your cluster does not have DRS fully automated, the Rebalance Container action notifies you that one or more clusters under the selected container do not have DRS set to fully automated.

To ensure that the Rebalance Container action is available in your environment, you must add DRS. Then, wait one collection cycle for the Rebalance Container action to appear.

### You Must Have Access to All Objects in the Container

If you have access to all objects in a cluster, data center, or custom data center, you can run the Rebalance Container action to move virtual machines to other clusters. When you do not have access to all of the objects in the container, the Rebalance Container action is not available.

## How the Rebalance Container Action Works

If two data centers are experiencing extreme differences in workload - one high and one low - use the Rebalance Container action to balance the workload across those objects. For example, if the CPU demand on a host in one data center exceeds its available CPU capacity, critical pressure occurs on the host. To identify the cause of stress, monitor the CPU demand. Some virtual machines on each host might be experiencing high CPU demand, whereas others might be experiencing a low demand.

The Rebalance Container action moves all affected objects in the suggested list provided by the action to balance the workload. If you do not want to act on the entire set of objects to resolve the problem with workload, you can use the Move VM action to move an individual object.

> **Important:**
> Do not attempt to move virtual machines that are members of a vApp, because the vApp can become nonfunctional. Instead, add affinity rules for these virtual machines to keep them together so that the Move VM and Rebalance Container actions will ignore them.

When workloads become imbalanced, the following alerts can trigger on data centers and custom data centers. These alerts are deactivated by default in the policies.

- Custom data center has unbalanced workload
- Data center has unbalanced workload

When the workloads on hosts in a data center or custom data center differ significantly, click **Operate** > **Alerts** and verify whether the alert triggered. For example, to verify whether the alert triggered on a custom data center, check the alert named `Custom data center has unbalanced workload`. You can click the alert to view the causes of the alert and identify the source of the imbalance problem on the **Summary** tab.

To display the recommendations about the objects to move so that you can rebalance the workload, click the **Rebalance Container** action on the **Summary** tab. The recommendations indicate that you move one or more virtual machines to another host. When you click **OK**, a pop-up message provides a link to track the status of the action in **Recent Tasks**.

The action moves the virtual machines identified in the recommendation to the host machine that has a low workload or stress. You can view the status of the action in the list of recent tasks in **Administration** > **Control Panel**, and then click the **Recent Tasks** tab. You can also use the vSphere Web Client to view the status of the action and the performance for the host.

After the action runs and VCF Operations performs several collection cycles, view the workload on the data center to confirm that the workload was rebalanced and that the alert is gone.

## Where You Run the Action

You can run the Rebalance Container action from the Actions menu for a data center or custom data center, or you can provide it as a suggested action on an alert.

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

## Action Recommendations

Review the following information about the hosts and virtual machines to ensure that you are submitting the action for the correct objects.

| Option | Description |
|---|---|
| Virtual Machine | Name of the virtual machine on the host that is experiencing an excessive workload. |
| Source Cluster | Name of the cluster on which the virtual machine is running. |
| Datastores | Datastore associated with the virtual machine. |

| Option | Description |
|---|---|
| Destination Cluster | Cluster where the virtual machine is to be moved. DRS selects the host automatically. |
| Reason | Describes the action to be taken and the reason why the move is suggested. For example, the recommendation is to move part of the workload on the cluster to another cluster to reduce the imbalance in CPU demand. |
| Parent vCenter | Identifies the vCenter Server adapter associated with the affected cluster. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1216: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Delete Idle VM Action

The Delete Idle VM action in VCF Operations removes from your vCenter instances those selected virtual machines that are in an idle state. Use this action to reclaim redundant resources.

#### How the Action Works

The Delete Idle VM action removes from your vCenter instances those virtual machines that are powered on, but that are in an idle state.

#### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

#### Action Menu Items

Review the following information about the virtual machines to ensure that you are submitting the action for the correct objects.

| Menu Items | Description |
|---|---|
| Name | Name of the virtual machine as it appears in the environment inventory. |
| Host | Name of the host on which the virtual machine is running. |
| Parent vCenter | Parent vCenter instance where the virtual machine resides. |

After you click **Begin Action**, the next dialog box provides the task ID and a link to the task list.

**Table 1217: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Set DRS Automation Action

You can monitor and configure the vSphereDistributed Resource Scheduler (DRS) automation rules from VCF Operations. DRS monitors and allocates the resources in your environment, and balances the computing capacity across your hosts and virtual machines.

#### How the Action Works

The Set DRS Automation action monitors and configures DRS automation rules. With the Set DRS Automation action, you can activate and deactivate DRS.

If VCF Automation manages any of the virtual machines in your environment, the Set DRS Automation action is not available for that object.

#### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

#### Action Menu Items

To ensure that you are submitting the correct action for the correct objects, review the following information about the clusters.

| Menu Items | Description |
|---|---|
| Name | Name of the cluster in the vCenter instance. |
| Automation Level | Level of DRS automation. When DRS is fully automated on the selected cluster, you can run the Set DRS Automation action. |
| Migration Threshold | Recommendations for the migration level of virtual machines. Migration thresholds are based on DRS priority levels, and are computed based on the workload imbalance metric for the cluster. |
| Parent vCenter | Parent vCenter instance where the cluster resides. |

After you click **Begin Action**, the next dialog box provides the task ID and a link to the task list.

**Table 1218: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Execute Custom Scripts

To troubleshoot particular processes, you can upload a script or run a command to receive specific information. You can view the standard output or standard error as applicable.

### Where You Run the Action

For supported objects and object levels, n the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**, and then select the relevant VM from the Inventory tree. This action is available from the **Actions** menu just below the top menu in VCF Operations.

### Prerequisites

- VMware Tools must be installed and running on the VM.
- vCenter is activated with the successful discovery of VMs.
- The VM must be powered on and connected.
- When you perform the Execute Custom Script action and you need to use `command/utilities`, for those commands that need a sudo user password provision, the full path of `command/utility` must be added to the NOPASSWD commands list.

The configured vCenter user must have the following privileges:

- key: VirtualMachine.GuestOperations.Execute, Localization: Guest operations -> Guest operation program execution
- key: VirtualMachine.GuestOperations.Query, Localization: Guest operations -> Guest operation queries
- The ESX instance that hosts the VMs where scripts should be run, must have HTTPS access to port 443 from the collector node on which the vCenter adapter instance is configured.
- The provided user in the script must have read and write privileges to the temp directory. For Windows systems, the path can be taken from the environment variable `TEMP`. For Linux systems, it is `/tmp` and/or `/var/tmp`.

### Action Options

Enter the VM credentials to authenticate even when the VM guest OS authentication status is "Success". You can run a script by entering it directly or by uploading a script file by optionally providing arguments.

| Option | Description |
|---|---|
| Upload File | Use this option to browse and upload the script that you want to run. |
| File | Browse and upload the script file. |
| Args | List the arguments in the script. |
| Command | Select the option and enter a command in the text box. |
| Timeout | Script execution timeout on VMs. Script execution continues even if the dialog box is closed. You can verify the status from **Recent Tasks**. |
| Execute | Runs the script or command. |
| stdout | Displays the standard output. |
| stderr | Displays errors, if any. |

## Get Top Processes Action

The Get Top Processes action is used for troubleshooting process issues and resource issues related to the applications of the virtual machine.

### How the Action Works

The Get Top Processes action, provides the status of top 10 processes for the selected virtual machine. You can troubleshoot issues related to the resources that are affecting the applications in the virtual machine.

By default, the details of top 10 processes are displayed for the selected virtual machine. You can change the number of processes and view the details for top N processes where N is between 1-100. You have the option to view the processes based on CPU and Memory.

The Get Top Processes action is run on both Windows virtual machine and Linux virtual machine. You can view the summary information for the commands only in a Linux virtual machine.

### Where You Run the Action

For supported objects and object levels, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**, and then select the relevant VM from the Inventory tree. This action is available from the **Actions** menu just below the top menu in VCF Operations.

### Prerequisites

- VMware Tools must be installed and running on the VM.
- Service discovery is activated with the successful discovery of VMs.
- The VM must be powered on and connected.

### Action Options

You must enter the VM credentials to authenticate when the VM is monitored in a credential-less mode or when the VM is monitored in a credential-based mode where the user is not authenticated. To ensure that you are taking the right action, review the following information.

| Option | Description |
|---|---|
| Number of Processes | Displays the number of processes for which the details are displayed. |
| Refresh | Displays new data about processes, when you change the value for the number of processes. |
| Command | Displays the name of the application |
| PID | Displays the process ID. |
| CPU | Displays the CPU usage in percentage for Linux VMs.<br>Displays the CPU usage in seconds for Windows VMs. The count starts when you start the operating system in the VM . |
| Mem (%) | Displays the Memory usage in KB. |
| User | Displays the user name. |
| Status | Displays the process status. It can be in one these states:<br>• For Linux - I, R, S<br>• For Windows - Unknown, Running, and Sleeping |
| Run | Displays data about the specified numbers of processes. |

## Move Virtual Machine Action

You can use the Move VM action to move virtual machines from one host and datastore to another host and datastore to balance the workload in your environment.

### How the Action Works

When you initiate this action, the **Move VM** wizard opens and scopes the possible destinations. You select the destination host and datastore from the list of available destinations.

To see all destinations, you must have view access to the following object types:

- Scope object, which includes a vCenter, data center, custom data center, or cluster.
- Host in the scope object.
- Datastore in the host.

The destinations include combinations of objects for the move, such as a specific host and datastore, or a different host with the same datastore. You select one of the available combinations. If your environment includes many destination objects, such as many hosts or datastores, enter text in the filter text box to search for specific destination objects.

The **All Filters** option helps you to move the VM according to the following action option:

- Destination Host
- Destination Datastore
- Will it Fit
- VM PowerOff Required
- Affinity Rules

VCF Operations uses vSphere DRS rules that you define in vCenter to help determine good placement decisions for your virtual machines in the move action. The Affinity Rules column indicates whether those rules are violated by the Move VM action.

> **Important:**
> Do not attempt to move virtual machines that are members of a vApp, because the vApp can become nonfunctional. Instead, add affinity rules for these virtual machines to keep them together so that the Move VM and Rebalance Container actions will ignore them.

To initiate the action, you click the **Begin Action** button.

When you finish the wizard, VCF Operations displays a dialog box to indicate that the action has started. To track the status of the action, click the link in the dialog box and view the state of the action in **Recent Tasks**.

### Moving Virtual Machines is Not Allowed Across Data Centers

When you attempt to use the **Move VM** action to move a virtual machine across data centers, VCF Operations must be able to identify the matching network and storage objects for the destination data center. Network objects include VMware virtual switches and distributed virtual switches. Storage objects include datastores and datastore clusters.

Moving a virtual machine across data centers requires VCF Operations to move the virtual machine files and change the virtual machine network configuration. VCF Operations does not currently move the virtual machine files across datastores, nor does it change the virtual machine network configuration. As a result, VCF Operations does not allow you to move virtual machines across data centers.

When you use the **Move VM** action, be aware of the following behavior:

- If you select a single virtual machine, VCF Operations displays the data center where the virtual machine resides.
- If you select multiple virtual machines, but those virtual machines do not share a common data center, the **Move VM** action does not display the data centers, and the **Move VM** action does not appear in the actions menu.

### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

### Action Options

Review the following information about the virtual machines to ensure that you are submitting the action for the correct objects.

| Option | Description |
|---|---|
| Priority | Indicates the priority of the proposed move destination. When the action is automated, the proposed destination with priority of 1 is automatically selected. |
| Destination Host | Name of the host to which the virtual machine will be moved. |
| Current CPU Workload | Amount of CPU in GHz available on the host. |
| Current Memory Workload | Amount of memory in GB available on the host. |
| Destination Datastore | Datastore to which the virtual machines storage will be moved. |
| Current Disk Space Workload | Amount of disk space available on the datastore. |

| Option | Description |
|---|---|
| Will it fit | Calculated estimation of whether the virtual machine fits on the selected destination. |
| VM Power Off Required | When set to `No`, the action does not power off the virtual machine before the move. When set to `Yes`, the action powers off the virtual machine before the move takes place, and powers on the virtual machine after the move is complete. If VMware Tools is installed, a guest OS shutdown is used to power off the virtual machine. |
| Affinity Rules | Indicates whether vSphere DRS rules exist, as defined in vCenter. For example, a rule might exist to keep virtual machines together, and another rule might exist to separate virtual machines.<br>This column indicates the following status.<br>• Empty. vSphere DRS rules are not defined.<br>• Green check mark. The move of virtual machines does not violate affinity rules.<br>• Red circle with bar. The move of virtual machines does break affinity rules. If you choose to break the affinity rules, you must resolve any problems manually. |
| Affinity Rule Details | Identifies the virtual machine and the vSphere DRS rule name as defined in vCenter. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1219: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Power Off Virtual Machine Action

The Power Off VM action in VCF Operations stops one or more selected virtual machines that are in a powered on state. You power off a virtual machine when you are managing resources and reclaiming wasted space.

#### How the Action Works

The Power Off VM action turns off the virtual machine. If VMware Tools is installed and running, the guest operating system is shut down before the machine is powered off. If VMware Tools is not installed and running, the virtual machine is powered off regardless of the state of the guest operating system. In this case, use this action only when you are powering off virtual machines where stopping the guest operating system does not adversely affect the installed applications.

If the target virtual machine is already powered off, the recent task status reports success on the machine, even though the state of the virtual machine did not change.

#### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

### Action Options

Review the following information about the virtual machines to ensure that you are submitting the action for the correct objects.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| Power State | Indicates whether the virtual machine is powered on or powered off. |
| Idle VM | Indicates whether the virtual machine is considered to be in the idle state based on the configured idle virtual machine metric. Possible values include:<br>• false. The virtual machine is active.<br>• true. The virtual machine is idle.<br>• unknown. VCF Operations does not have the data required to calculate the idle metric. |
| Idle VM Percentage | Calculated threshold of the idle virtual machine percentage based on the configured reclaimable wasted space policy. |
| CPU Usage Percentage | Calculated threshold of the virtual machine CPU percentage based on the metric named `cpu \| usage_average`. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1220: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Shut Down Guest Operating System for Virtual Machine Action

The Shut Down Guest OS for VM action shuts down the guest operating system and powers off the virtual machine. You shut down a virtual machine when you are managing resources and reclaiming wasted space.

### How the Action Works

The Shut Down Guest OS for VM action checks that VMware Tools, which is required, is installed on the target virtual machines, then shuts down the guest operating system and powers off the virtual machine. If VMware Tools is not installed or installed but not running, the action does not run and the job is reported as failed in **Recent Tasks**.

If the target virtual machine is already powered off, the recent task status reports success on the machine, even though the state of the virtual machine did not change.

### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

### Action Options

Review the following so you can be sure you are taking the right action.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| Power State | Indicates whether the virtual machine is powered on or powered off. |
| Idle VM | Indicates whether the virtual machine is considered to be in the idle state based on the configured idle virtual machine metric.<br>Possible values include:<br>• false. The virtual machine is active.<br>• true. The virtual machine is idle.<br>• unknown. VCF Operations does not have the data required to calculate the idle metric. |
| Idle VM Percentage | Calculated threshold of the idle virtual machine percentage based on the configured reclaimable wasted space policy. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1221: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Reboot Guest OS for Virtual Machine Action

The Reboot Guest OS for VM action reboots the guest operating system and the virtual machine. You reboot a virtual machine while managing resources or when you have new updates or configuration changes to your virtual machine.

### How the Action Works

The Reboot Guest OS for VM action checks that VMware Tools, which is required, is installed on the target virtual machines, then reboots the guest operating system and the virtual machine. If VMware Tools is not installed or installed but not running, the action does not run, and the job is reported as failed in **Recent Tasks**.

### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**, and select an object in the list.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**, select an object, click the **Environment** tab, and select an object in the list view.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

### Action Options

Review the following so you can be sure you are taking the right action.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| Host | Name of the host on which the virtual machine is running. |
| Parent vCenter | The adapter instance as configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1222: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

## Power on Virtual Machine Action

To start one or more virtual machines that are in a powered off state, use the Power On VM action. You power on a virtual machine so that you can shift resources. For example, power on a machine so that you can use it, run applications, or verify that actions that were run on already powered down machines contribute to improved performance.

### How the Action Works

The Power On VM action powers on virtual machines that are powered off. The action does not affect virtual machines that are currently powered on.

If the target virtual machine is already powered on, the task status reports success for the machine even though the state of the virtual machine did not change.

### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

### Action Options

To ensure that you are taking the right action, review the following information.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| Power State | Indicates whether the virtual machine is powered on or powered off. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1223: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

## Delete Powered Off Virtual Machine Action

The Delete Powered Off VM action in VCF Operations removes selected virtual machines that are in a powered off state from your vCenter instances. Use this action to reclaim redundant resources.

### How the Action Works

The Delete Powered Off VM action removes virtual machines from the vCenter instances. If the virtual machine is powered on, the action does not delete the virtual machine.

### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operation** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

## Action Options

To ensure that you are submitting the action for the right objects, review the following information.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| Power State | Indicates whether the virtual machine is powered on or powered off. |
| Disk Space | Amount of disk space currently consumed by the virtual machine. |
| Snapshot Space | Amount of disk space currently consumed by the virtual machine snapshots. |
| Memory (MB) | Amount of memory allocated to the virtual machine. |
| CPU Count | Number of CPUs currently configured for the virtual machine. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1224: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Set Memory for Virtual Machine Action

The Set Memory for VM action in VCF Operations is used to add or remove memory on virtual machines. You increase the memory to address performance problems or decrease the memory to reclaim resources.

## How the Action Works

The Set Memory for VM action perform several tasks. The action determines the power state of the target virtual machines, takes a snapshot when you request it and powers off the machine if necessary and you request it. As well, the action changes the memory to the new value, and returns the virtual machines their original power states.

An alternative form of the Set Memory for Virtual Machine action is available for automation. This action can run when the virtual machine is powered on or off.

Use this version of the action if the automated action has permission to power off the virtual machine, and hot add of memory is not activated on the virtual machine. With hot add activated, you can add memory, but you cannot remove it.

This version of the action would be required if a virtual machine is powered on and the amount of memory must be reduced.

This version of the action has the Power Off Allowed flag set to true. You can select this Power Off Allowed version of the action when you create or edit alerts and associate the alert with a recommendation. When the Power Off Allowed version of this action is automated, you do not select this version of the action.

If Hot Plug is activated on the virtual machines, then power off is not required. If power off is required and VMware Tools is installed, then the virtual machines are shut down before they are powered off.

### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

### Action Options

Review the following information about the virtual machines to ensure that you are submitting the action for the correct objects.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected.<br>If you modify a value, the check box is selected. The check box must be selected to activate the OK button. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| New CPU | Number of CPUs when the action is completed. If the value is less than 1 or a value not supported for the virtual machine in vCenter, and the virtual machine is powered on and Hot Add is not activated, the number of CPUs does not change and Recent Tasks shows the action as failed. If the virtual machine is powered off when you submit an unsupported value, the task reports success, but the virtual machine will fail when you run a power on action.<br>The value that appears is the calculated suggested size. If the target virtual machine is new or offline, this value is the current number of CPUs. If VCF Operations has been monitoring the virtual machine for six or more hours, depending on your environment, the value that appears is the CPU Recommended Size metric. |
| Current CPU | Number of configured CPUs. |
| Power State | Indicates whether the virtual machine is powered on or powered off. |
| Power Off Allowed | If selected, the action shuts down or powers off the virtual machine before modifying the value. If VMware Tools is installed and running, the virtual machine is shut down. If VMware Tools is not installed or not running, the virtual machine is powered off without regard for the state of the operating system.<br>In addition to whether the action shuts down or powers off a virtual machine, you must consider whether the object is powered on and what settings are applied.<br>See Working with Actions That Use Power Off section in *VCF Operations Configuration Guide.* . |

| Option | Description |
|---|---|
| Snapshot | Creates a snapshot before changing the number of CPUs. Use this option if you need a snapshot to which you can revert the virtual machine if the action does not produce the expected results.<br>The name of the snapshot is supplied in the Recent Tasks messages for the action.<br>If the CPU is changed with CPU Hot Plug activated, then the snapshot is taken with the virtual machine is running, which consumes more disk space. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1225: Task ID Dialog Box**

| Option | Description |
|---|---|
| OK | To close the dialog box without further action, click **OK**. |
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |

### Set Memory Resources for Virtual Machine Action

The Set Memory Resources for VM action is used to modify the memory reservation and memory limit on virtual machines. You modify the memory reservation and limit to manage resources in your environment, either to reclaim unused resources or to ensure that your virtual machines have the resources they need to run efficiently.

#### How the Action Works

The Set Memory Resources for VM action determines how memory resources are allocated to the virtual machine. The reservation value is the minimum amount of guaranteed memory allocated for the virtual machine. The limit is the maximum amount of memory that the virtual machine can consume.

The reservation and limit values in vCenter are set in megabytes. VCF Operations calculates and reports on memory in kilobytes. When you run this action, the values are presented in kilobytes so that you can implement recommendations from VCF Operations.

To run the action, all options must be configured in the dialog box for the objects on which you are running the action. If you are changing one option to a new value, but not another option, ensure that the option that you do not want to change is configured with the current value.

#### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

## Action Options

To ensure that you are submitting the action for the right objects, review the following information.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected.<br>If you modify a value, the check box is selected. The check box must be selected to activate the OK button. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| New Resv (KB) | Amount of memory in kilobytes reserved for the virtual machine when the action is finished. The new reservation value must be less than or equal to the new limit value unless your new limit is unlimited (-1).<br>The reservation supports the following possible values:<br>• If you set the value to 0, the virtual machine is allocated only the currently configured amount of RAM.<br>• If you add or remove reserved memory, the value must be evenly divisible by 1024. |
| Current Resv (KB) | Amount of memory in kilobytes that is configured as the guaranteed memory for the virtual machine. |
| New Limit (KB) | Maximum amount of memory in kilobytes that the virtual machine can consume when the action is completed.<br>The limit supports the following possible values:<br>• If you set the value to 0, then the maximum memory is no greater than the allocated reservation amount.<br>• If you set the value to -1, then the virtual machine memory is unlimited.<br>• It you increase or decrease the limit, the value must be evenly divisible by 1024. |
| Current Limit (KB) | Maximum amount of memory that the virtual machine is currently allowed to consume. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1226: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Set CPU Count for Virtual Machine Action

The Set CPU action modifies the number of vCPUs on a virtual machine. You increase the number of CPUs to address performance problems or decrease the number of CPU to reclaim resources.

## How the Action Works

The Set CPU Count action shuts down or powers off the target virtual machines. If you are decreasing the CPU count, the action is required. This action creates a snapshot if you request it, changes the number of vCPUs based on the new CPU count you provided, and returns the virtual machines to their original power states.

An alternative form of the Set CPU Count for Virtual Machine action is available for automation. This action can run when the virtual machine is powered on or off.

Use this version of the action if the automated action has permission to power off the virtual machine, and hot add of memory is not activated on the virtual machine. With hot add activated, you can add CPUs, but you cannot remove them.

This version of the action is required if a virtual machine is powered on and the number of CPUs must be reduced.

This version of the action has the Power Off Allowed flag set to true. You can select this Power Off Allowed version of the action when you create or edit alerts and associate the alert with a recommendation. When the Power Off Allowed version of this action is automated, you do not select this version of the action.

If Hot Plug is activated on the virtual machines, then power off is not required. If power off is required and VMware Tools are installed, then the virtual machines are shut down before they are powered off.

## Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

## Action Options

Review the following information about the virtual machines to ensure that you are submitting the action for the correct objects.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected.<br>If you modify a value, the check box is selected. The check box must be selected to activate the OK button. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| New CPU | Number of CPUs when the action is completed. If the value is less than 1 or a value not supported for the virtual machine in vCenter, and the virtual machine is powered on and Hot Add is not activated, the number of CPUs does not change and Recent Tasks shows the action as failed. If the virtual machine is powered off when you submit an unsupported value, the task reports success, but the virtual machine will fail when you run a power on action.<br>The value that appears is the calculated suggested size. If the target virtual machine is new or offline, this value is the current number of CPUs. If VCF Operations has been monitoring the virtual machine for six or more hours, depending on your environment, the value that appears is the CPU Recommended Size metric. |
| Current CPU | Number of configured CPUs. |

| Option | Description |
|---|---|
| Power State | Indicates whether the virtual machine is powered on or powered off. |
| Power Off Allowed | If selected, the action shuts down or powers off the virtual machine before modifying the value. If VMware Tools is installed and running, the virtual machine is shut down. If VMware Tools is not installed or not running, the virtual machine is powered off without regard for the state of the operating system.<br>In addition to whether the action shuts down or powers off a virtual machine, you must consider whether the object is powered on and what settings are applied.<br>See Working with Actions That Use Power Off section in *VCF Operations Configuration Guide*. . |
| Snapshot | Creates a snapshot before changing the number of CPUs. Use this option if you need a snapshot to which you can revert the virtual machine if the action does not produce the expected results.<br>The name of the snapshot is supplied in the Recent Tasks messages for the action.<br>If the CPU is changed with CPU Hot Plug activated, then the snapshot is taken with the virtual machine is running, which consumes more disk space. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1227: Task ID Dialog Box**

| Option | Description |
|---|---|
| OK | To close the dialog box without further action, click **OK**. |
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |

### Set CPU Resources for Virtual Machine Action

The Set CPU Resources for VM action is used to modify the CPU reservation and CPU limit on virtual machines. You modify the CPU reservation and limit to manage workload demands in your environment.

#### How the Action Works

The Set CPU Resources for VM action determines how CPU resources can be allocated to the virtual machines. The reservation limit is the minimum amount of guaranteed CPU resources allocated to the virtual machine. The limit is the maximum amount of CPU resources that the virtual machine can consume.

To run the action, all options where you configure a value must contain a value for the objects that you want to change. If you are changing one option to a new value, but not another option, ensure that the option that you are not changing is configure with the current value.

#### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

**Action Options**

To ensure that you are submitting the action for the right objects, review the following information.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected.<br>If you modify a value, the check box is selected. The check box must be selected to activate the OK button. |
| Name | Name of the virtual machine as it appears in the environment inventory. |
| New Resv (MHz) | Amount of CPU resources in megahertz reserved for the virtual machine when the action is finished. The new reservation value must be less than or equal to the new limit value unless your new limit is unlimited (-1).<br>The reservation supports the following possible values:<br>• If you set the value to 0, the virtual machine is allocated only the configured CPU consumption level.<br>• If you add or removed reserved CPU consumption, supply a positive integer unless you set the value to 0. |
| Current Resv (MHz) | Amount of CPU resources that is configured as the guaranteed CPU resources for the virtual machine. |
| New Limit (MHz) | Maximum amount of CPU consumption in megahertz that the virtual machine can consume when the action is completed.<br>The limit supports the following possible values:<br>• If you set the value to 0, the maximum CPU consumption is not greater than the allocated reservation amount.<br>• If you set the value to -1, then the virtual machine CPU consumption is unlimited.<br>• If you add or remove CPU consumption limits, supply a positive integer, unless you set the value to 0 or -1. |
| Current Limit (MHz) | Maximum amount of CPU that the virtual machine can consume. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1228: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

### Set CPU Count and Memory for Virtual Machine Action

The Set CPU Count and Memory for VM action is used to add or remove CPUs and memory on virtual machines with only one power off of the virtual machines to perform the combined actions. You modify the CPU and memory to address performance problems or to reclaim resources.

#### How the Action Works

The Set CPU Count and Memory action powers off the target virtual machines. The action also creates a snapshot when requested and changes the number of vCPUs and memory based on the new CPU count and memory values you provided. As well, the action returns the virtual machines their original power states.

An alternative form of the Set CPU Count and Memory for Virtual Machine action is available for automation. This version of the action has the Power Off Allowed flag set to true so that the action is available for automation and can run when the virtual machine is in the powered on state. You can select the Power Off Allowed version of the action when you create or edit alerts and associate the alert with a recommendation. When the Power Off Allowed version of this action is automated, you do not select this version of the action.

If Hot Plug is activated on the virtual machines, then power off is not required. If power off is required and VMware Tools are installed, then the virtual machines are shut down before they are powered off.

To run the action, all options where you configure a value must contain a value for the objects that you want to change. If you are changing one option to a new value, but not another option, ensure that the option that you are not changing is configure with the current value.

#### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

#### Action Options

Review the following information about the virtual machines to ensure that you are submitting the action for the correct objects.

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected.<br>If you modify a value, the check box is selected. The check box must be selected to activate the OK button. |
| Name | Name of the virtual machine as it appears in the environment inventory. |

| Option | Description |
|---|---|
| New CPU | Number of CPUs when the action is completed. If the value is less than 1 or a value not supported for the virtual machine in vCenter, and the virtual machine is powered on and Hot Add is not activated, the number of CPUs does not change and Recent Tasks shows the action as failed. If the virtual machine is powered off when you submit an unsupported value, the task reports success, but the virtual machine will fail when you run a power on action.<br>The value that appears is the calculated suggested size. If the target virtual machine is new or offline, this value is the current number of CPUs. If VCF Operations has been monitoring the virtual machine for six or more hours, depending on your environment, the value that appears is the CPU Recommended Size metric. |
| Current CPU | Number of configured CPUs. |
| Power State | Indicates whether the virtual machine is powered on or powered off. |
| Power Off Allowed | If selected, the action shuts down or powers off the virtual machine before modifying the value. If VMware Tools is installed and running, the virtual machine is shut down. If VMware Tools is not installed or not running, the virtual machine is powered off without regard for the state of the operating system.<br>In addition to whether the action shuts down or powers off a virtual machine, you must consider whether the object is powered on and what settings are applied.<br>See Working with Actions That Use Power Off section in *VCF Operations Configuration Guide*. . |
| Snapshot | Creates a snapshot before changing the number of CPUs. Use this option if you need a snapshot to which you can revert the virtual machine if the action does not produce the expected results.<br>The name of the snapshot is supplied in the Recent Tasks messages for the action.<br>If the CPU is changed with CPU Hot Plug activated, then the snapshot is taken with the virtual machine is running, which consumes more disk space. |
| Host | Name of the host on which the virtual machine is running. |
| Adapter Instance | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1229: Task ID Dialog Box**

| Option | Description |
|---|---|
| OK | To close the dialog box without further action, click **OK**. |
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |

### Delete Unused Snapshots for Virtual Machine Action

The Delete Unused Snapshots for Virtual Machines action in VCF Operations deletes snapshots that are older than the specified age from your datastores. Deleting unused snapshots reclaims wasted space in your environment.

### How the Action Works

The Delete Unused Snapshots for Virtual Machine action comprises two dialog boxes. The first dialog box allows you to select the snapshot age criteria, which must be greater than one day. The second step allows you to select the snapshots to delete, and runs the Delete Unused Snapshots for Virtual Machine action.

The number of days that you specify for each virtual machine is the age of the snapshots based on the creation date. The Delete Unused Snapshots for Virtual Machine action retrieves the snapshot and displays the snapshot name, space consumed, and location so that you can evaluate the snapshots before you delete them.

When you click **Begin Action**, VCF Operations displays a dialog box to indicate that the action has started. To track the status of the action, click the link in the dialog box and view the state of the action in **Recent Tasks**.

### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

### Action Options

To ensure that you are submitting the action for the right objects, review the following information.

You first retrieve snapshots based on age, then select the snapshots to delete.

**Table 1230: Retrieve Snapshots**

| Option | Description |
|---|---|
| Name | Name of the virtual machine on which you are running the Delete Unused Snapshots for VM action. |
| Days Old | Age of the snapshots to be deleted. This action retrieves snapshots for the virtual machine that are older than one day. |
| Host | Name of the host with which the virtual machine is associated. |
| Parent vCenter | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

Select the snapshots to delete.

**Table 1231: Delete Snapshots**

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected. |
| VM Name | Name of the virtual machine from which the snapshot was created. |
| Snapshot Name | Name of the snapshot in the datastore. |
| Snapshot Space (MB) | Number of megabytes consumed by the snapshot. |
| Snapshot Create Time | Date and time when the snapshot was created. |
| Snapshot Age | Age of the snapshot in days. |
| Datacenter Name | Name of the data center with which the datastore is associated. |
| Datastore Name | Name of the datastore where the snapshot is managed. |
| Host Name | Name of the host with which the datastore is associated. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1232: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

The Delete Unused Snapshots action creates a job for the retrieve snapshots action, and a job for the delete snapshots action.

### Delete Unused Snapshots for Datastore Action

The Delete Unused Snapshots for Datastore action in VCF Operations deletes snapshots that are older than the specified age from your datastores. Deleting unused snapshots reclaims wasted space in your environment.

#### How the Action Works

The Delete Unused Snapshots for Datastore action comprises two dialog boxes. The first dialog box allows you to select the snapshot age criteria, which must be greater than one day. The second step allows you to select the snapshots to delete, and runs the Delete Unused Snapshots for Datastore action.

The number of days that you specify for each datastore is the age of the snapshots based on the creation date. The Delete Unused Snapshots dialog box provides details regarding snapshot name, space consumed, and location so that you can evaluate the snapshots before you delete them.

When you click **Begin Action**, VCF Operations displays a dialog box to indicate that the action has started. To track the status of the action, click the link in the dialog box and view the state of the action in **Recent Tasks**.

#### Where You Run the Action

For the supported objects and object levels, this action is available in the following locations in VCF Operations:

- Embedded just below the top menu.
- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations,** and then click the **Inventory Management** tile. Select an object in the list.
- In configured alert recommendations.
- In the Object List and Topology Graph dashboard widgets.

#### Action Options

To ensure that you are submitting the action for the right objects, review the following information.

You first retrieve snapshots based on age, then select the snapshots to delete.

**Table 1233: Retrieve Snapshots**

| Option | Description |
|---|---|
| Name | Name of the datastore on which you are running the delete snapshot action. |
| Days Old | Age of the snapshots to be deleted. This action retrieves snapshots for the datastore that are older than one day. |
| Host | Name of the host with which the datastore is associated. |
| Parent vCenter | Name of the VMware Adapter as it is configured in VCF Operations. The adapter manages the communication with the vCenter instance. |

Select the snapshots to delete.

**Table 1234: Delete Snapshots**

| Option | Description |
|---|---|
| Selected objects | Check box indicates whether the action is applied to the object. To not run the action on one or more objects, deselect the associated check boxes. This option is available when two or more objects are selected. |
| Datastore Name | Name of the datastore where the snapshot is managed. |
| Snapshot Name | Name of the snapshot in the datastore. |
| Snapshot Space (MB) | Number of megabytes consumed by the snapshot. |
| Snapshot Create Time | Date and time when the snapshot was created. |
| Snapshot Age | Age of the snapshot in days. |
| Datacenter Name | Name of the data center with which the datastore is associated. |
| Host Name | Name of the host with which the datastore is associated. |
| VM Name | Name of the virtual machine from which the snapshot was created. |

After you click **OK**, the next dialog box provides the task ID and a link to the task list.

**Table 1235: Task ID Dialog Box**

| Option | Description |
|---|---|
| Recent Tasks | To view the status of the job and verify that the job finished, click **Recent Tasks**. |
| OK | To close the dialog box without further action, click **OK**. |

The Delete Unused Snapshots action creates a job for the retrieve snapshots action, and a job for the delete snapshots action.

**Power On, Power Off, and Reboot Actions**

You can run Power On, Power Off, and Reboot actions for AWS, Azure, and GCP using VCF Operations. These actions allow you to manage your objects and respond quickly to alerts. You can power on an instance to start collecting data, run applications, or verify the actions that were run on already powered-down machines. You can power off or reboot an instance to manage resources and reclaim wasted space.

- To run actions for AWS, ensure your account ID has the following privileges: **ec2:StartInstances**, **ec2:StopInstances** , and **ec2:RebootInstances**.
- To run actions for Azure, ensure you have one of the following privileges: **contributor**, **owner**, **virtual machine contributor**, and **avere contributor**.
- To run actions for GCP, ensure you have one of the following privileges: **owner**, **compute admin**, and **Compute Instance Admin (v1)**.

1. To perform actions on a single instance:
   a) In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**.
   b) In the **Accounts** tab, click the vertical ellipses against the AWS, Microsoft Azure, or GCP Cloud Account, and then select **Object Details**.

      The Object Browser page is displayed.

c) Locate the EC2 Instance, Azure Virtual Machine, or CE Instance and click **Actions**.

2. Optional: To perform actions on multiple instances at once:
   a) From the left menu click **Inventory**.
   b) Navigate to the AWS, Microsoft Azure, or GCP instance and filter by object type.
   c) Select multiple objects and click the **Actions** icon.
3. Select one of the following actions.

   The Actions vary based on the instance you are using.

   **Note:**
   To start an instance that is in a powered-off state, use the Power On action. The Power Off and Reboot actions appear only when the instance is in the Power On state.

| Accounts | Actions |
|---|---|
| AWS: EC2 Instance | • Power On Instance<br>• Power Off Instance<br>• Reboot Instance<br><br>**Note:**<br>These actions are available only if you activate actions while configuring an AWS account. For more information, see the "Add a Cloud Account for AWS" topic, in the *VCF Operations Configuration Guide*. |
| Microsoft Azure: Azure Virtual Machine | • Power On VM<br>• Power Off VM<br>• Reboot VM<br><br>**Note:**<br>These actions are available only if you activate actions while configuring a Microsoft Azure account. For more information, see the "Add a Cloud Account for Microsoft Azure" topic, in the *VCF Operations Configuration Guide*. |
| GCP: CE Instance | • Power On CE Instance<br>• Power Off CE Instance<br>• Reboot CE Instance<br><br>**Note:**<br>These actions are available only if you activate actions while configuring a GCP account. For more information, see the "Configuring Google Cloud Platform" topic, in the *VCF Operations Configuration Guide*. |

4. Click **Begin Action** and then, click **OK**.

Click **Recent Tasks** under **Administration** > **Control Panel** to verify the status of the action.

## Troubleshoot Actions in VCF Operations

If you are missing data or cannot run actions from VCF Operations, review the troubleshooting options.

Verify that your vCenter Adapter is configured to connect to the correct vCenter instance, and configured to run actions.

Verify that your vCenter Adapter is configured to connect to the correct vCenter instance, and configured to run actions.

**Actions Do Not Appear on Object**
An action might not appear on an object, such as a host or virtual machine, because VCF Automation is managing that object.

Actions such as Rebalance Container might not appear in the drop-down menu when you view the actions for your data center.

- If a data center is managed by VCF Automation, actions do not appear.
- If a data center is not managed by VCF Automation, you can act on the virtual machines that VCF Automation is not managing.

When VCF Automation manages the child objects of a data center or custom data center container, the actions that are normally available on those objects do not appear. They are not available because the action framework excludes actions on objects that VCF Automation manages. You cannot turn on or turn off the exclusion of actions on objects that VCF Automation manages. This behavior is normal.

If you removed the VCF Automation adapter instance, but did not select the **Remove related objects** check box, the actions are still disabled.

Make actions available on the objects in your data center or custom data center in one of two ways. Either confirm that VCF Automation is not managing the objects, or perform the steps in this procedure to remove the VCF Automation adapter instance.

1. To allow actions on an object, go to your VCF Automation instance.
2. Perform the action in VCF Automation, such as to move a virtual machine.

**Missing Column Data in Actions Dialog Boxes**
Data is missing for one or more objects in an Actions dialog box, making it difficult to determine if you want to run the action.

When you run an action one or more objects, some of the fields are empty.

There are two possible causes: 1) the VMware vSphere adapter has not collected the data from the vCenter instance that manages the object. 2) the current VCF Operations user does not have privileges to view the collected data for the object.

1. Verify that VCF Operations is configured to collect the data.
2. Verify that you have the privileges necessary to view the data.

**Missing Column Data in the Set Memory for VM Dialog Box**
The read-only data columns do not display the current values, which makes it difficult to specify properly a new memory value.

Current (MB) and Power State columns do not display the current values, which are collected for the managed object.

The adapter responsible for collecting data from the vCenter on which the target virtual machine is running has not run a collection cycle and collected the data. This omission can occur when you recently created an VMware adapter instance for the target vCenter and initiated an action. The VMware vSphere adapter has a five-minute collection cycle.

1. After you create a VMware adapter instance, wait an extra five minutes.
2. Rerun the **Set Memory for VM** action.

   The current memory value and the current power state appear in the dialog box.

**Host Name Does Not Appear in Action Dialog Box**
When you run an action on a virtual machine, the host name is blank in the action dialog box.

When you select virtual machine on which to run an action, and click the **Action** button, the dialog box appears, but the Host column is empty.

Although your user role is configured to run action on the virtual machines, you do not have a user roll that provides you with access to the host. You can see the virtual machines and run actions on them, but you cannot see the host data for the virtual machines. VCF Operations cannot retrieve data that you do not have permission to access.

You can run the action, but you cannot see the host name in the action dialog boxes.

## Monitor Recent Task Status

The Recent Task status includes all the tasks initiated from VCF Operations. You use the task status information to verify that your tasks finished successfully or to determine the current state of tasks.

You ran at least one action as part of an alert recommendation or from one of the toolbars. See Run Actions from Toolbars in VCF Operations.

You can monitor the status of tasks that are started when you run actions, and investigate whether a task finished successfully.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Control Panel**, and then select the **Recent Tasks** tile.
2. To determine if you have tasks that are not finished, click the **Status** column and sort the results.

| Option | Description |
|---|---|
| `In Progress` | Indicates running tasks. |
| `Completed` | Indicates finished tasks. |
| `Failed` | Indicates incomplete tasks on at least one object when started on multiple objects. |
| `Maximum Time Reached` | Indicates timed out tasks. |

3. To evaluate a task process, select the task in the list and review the information in the **Details of Task Selected** pane.

   The details appear in the Messages pane. If the information message includes `No action taken`, the task finished because the object was already in the requested state.
4. To view the messages for an object when the task included several objects, select the object in the Associated Objects list.

   To clear the object selection so that you can view all the messages, press the space bar.

Troubleshoot tasks with a status of `Maximum Time Reached` or `Failed` to determine why a task did not run successfully. See Troubleshoot Failed Tasks.

**Recent Tasks in VCF Operations**
The status of the tasks that were recently initiated from VCF Operationsappears in the Recent Task list. You can determine whether a task is finished, still in process, or failed.

### How Recent Tasks Work

The Recent Tasks page reports on logged task events, and the log entries appear in the messages area so that you can troubleshoot failed tasks.

### Where You View Recent Tasks

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Control Panel**, and then select the **Recent Tasks** tile.

### Recent Task Options

Review the information in the task list to determine if a task is completed or if you must troubleshoot a failed task. To see the details about a task, select the task in the list and review the associated objects and task messages.

**Table 1236: Task List**

| Option | Description |
|---|---|
| Export | Exports the selected task to an XML file.<br>The exported information, which includes the messages, is useful when you are troubleshooting a problem. |
| Edit Properties | Determines how long the recent task data is retained in your system.<br>Set the number of days that VCF Operations keeps the data, after which it is purged from the system. The default value is 90 days. |
| Status drop-down menu | Filters the list based on the status value. |

| Option | Description |
| --- | --- |
| All Filters | Filters the list based on the selected column and the provided values. You can filter the tasks based on the following criteria.<br>• Task<br>• Started Time<br>• Completed Time<br>• Automated<br>• Object Name<br>• Object Type<br>• Event Source<br>• Source Type<br>• Submitted By<br>• Task ID |
| Filter (Object Name) | Limits the tasks in the list to those that match the entered string. The search is based on a partial entry. For example, if you enter `vm`, objects such as `vm001` and `acctvm_east` are included. |
| Task | Name of the task.<br>For example, Set CPU Count for VM. |
| Status | State of the task.<br>Possible states include the following values:<br>• Completed. Task completed successfully on the target objects.<br>• In Progress. Task is running on the target objects.<br>• Failed. Task failed to run on the target objects. If the task started, the reasons for failure might include a faulty script, a script timed out, or actions are not taken. If the task did not start and immediately reports as failed, the reasons might include that the task was not able to start or the script was not found. If the task was not initiated on the target object, it might have failed because of communication or authentication errors.<br>• Maximum Time Reached. Task is running past the amount of time that is the default or configured value. To determine the status, you must troubleshoot the initiated action.<br>• Not Dispatched. The action adapter was not found.<br>• Started. Task is initiated on the object.<br>• Unknown. An error occurred while running the action, but the error was not captured in the task logs. To investigate this status further, check the VCF Operations support logs for the vCenter Adapter, available in the **Administration** area, and check the target system. |
| Started Time | Date and time when the task started. |
| Completed Time | Date and time when the task finished.<br>A completed date does not appear if the task failed or if the maximum timeout is reached. |
| Automated | Indicates whether the action in the task list is automated, indicated by `Yes` or `No`. |
| Object Name | Object on which the task was started. |
| Object Type | Type of object on which the task was started. |

| Option | Description |
|---|---|
| Event Source | The UUID or the name of the event that triggered the action automatically. when an event is triggered that is associated to the recommendation, it triggers the action without the user intervention.<br>For example, you can automate Alert recommendations that have an associated action. Automation is disabled by default. You configure automation in the **Override Alert / Symptom Definitions** area of a policy when you create or edit the policy in the **Policy Definition** tile.<br>An administrator who has the **Automation** role has permission to automate actions in the **Override Alert / Symptom Definitions** area of the policy workspace. |
| Source Type | Authentication source that the user who started the task used when accessing VCF Operations. |
| Submitted By | Name of the user who initiated the task. This column displays the automationAdmin user account for automated actions that are triggered by alerts. |
| Task ID | ID generated when the task, which included one or more actions, was started.<br>The task ID is unique for the task for each adapter. If a task includes tasks that ran using two adapters, you see two task IDs.<br>If the task is a delete snapshot action, two task IDs are generated. One ID is for the retrieve snapshots based on date task, and the other ID is for the delete selected snapshots task. |

The Associated Objects are the objects on which the selected task ran.

**Table 1237: Associated Objects for Selected Task Details**

| Option | Description |
|---|---|
| Object Name | Detailed list of objects that are included in the task selected in the task list.<br>If the task ran on only one object, the list includes one object.<br>If the task ran on multiple objects, each object is listed on a separate row. |
| Object Type | Type of object for each object name. |
| Status | Current state of the task. |
| The following are columns displayed for a Workload Optimization task | |
| Source Cluster | The source Cluster from which the VM is moved during Workload Optimization. |
| Destination Cluster | The destination Cluster to which the VM is moved during Workload Optimization. |
| Source Host | The source Host from which the VM is moved during Workload Optimization. |
| Destination Host | The destination Host to which the VM is moved during Workload Optimization. |
| Source Datastore | The source Datastore from which the VM is moved during Workload Optimization. |
| Destination Datastore | The destination Datastore to which the VM is moved during Workload Optimization. |
| Completion Date | The date when the task was completed. |

The Messages are the log of the task as it ran. If the task does not finish successfully, use the logs to identify problems.

**Table 1238: Messages for Selected Task Details**

| | |
|---|---|
| Severity drop-down menu | Limits the messages based on the Severity value. |
| Filter (Message) | Limits the message in the list to those that match the entered string.<br>The search is based on a partial entry. For example, if you enter `id`, then messages that contain `Task ID` and the phrase `did not complete` are included. |
| Severity | Message level in the logs.<br>The severity includes the following values:<br>• All. Displays all the messages.<br>• Error. Messages generated during a task failure.<br>• Warning. Messages generated as warning when the task is in progress.<br>• Information. Messages added to logs as the task is processed. |
| Time | Date and time the entry was added to the log. |
| Message | Text of the log entry.<br>Use the information in the message to determine why a task failed, and to begin to troubleshoot and resolve the failure.<br>The messages appear with the most recent entry at the top of the list if you do not sort the columns. |

## Troubleshoot Failed Tasks

If tasks fail to run in VCF Operations, review the Recent Tasks page and troubleshoot the task to determine why it failed.

This information is a general procedure for using the information in Recent Tasks to troubleshoot problems identified in the tasks.

**Determine If a Recent Task Failed**
The Recent Tasks provide the status of action tasks initiated from VCF Operations. If you do not see the expected results, review the tasks to determine if your task failed.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Control Panel**, and then select the **Recent Tasks** tile.
2. Select the failed task in the task list.
3. In the Messages list, locate the occurrences of `Script Return Result: Failure` and review the information between this value and `<-- Executing:[script name] on {object type}.`

   `Script Return Result` is the end of action run and `<-- Executing` indicates the beginning. The information provided includes the parameters that are passed, the target object, and unexpected exceptions that you can use to identify the problem.

**Troubleshooting Maximum Time Reached Task Status**
An action task has a `Maximum Time Reached` status and you do not know the status of the task.

The Recent Tasks list indicates that a task had a status of `Maximum Time Reached`.

The task is running past the amount of time that is the default or configured value. To determine the latest status, you must troubleshoot the initiated action.

The task is running past the amount of time that is the default or configured value for one of the following reasons:

- The action is exceptionally long running and did not finish before the threshold timeout was reached.
- The action adapter did not receive a response from the target system before reaching the timeout. The action might have completed successfully, but the completion status was not returned to VCF Operations.
- The action did not start correctly.

- The action adapter might have an error and be unable to report the status.

To determine whether the action completed successfully, check the state of the target object. If it did not complete, continue investigating to find the root cause.

**Troubleshooting Set CPU or Set Memory Failed Tasks**

An action task for Set CPU Count or Set Memory for VM has a `Failed` status in the recent task list because power off is not allowed.

The Recent Tasks list indicates that a Set CPU Count, Set Memory, or Set CPU and Memory task has a status of `Failed`. When you evaluate the Messages list for the selected task, you see this message.

```
Unable to perform action. Virtual Machine found
  powered on, power off not allowed.
```

When you increase the memory or CPU count, you see this message.

```
Virtual Machine found powered on, power off not allowed, if hot add is
  enabled the hotPlugLimit is exceeded.
```

You submitted the action to increase or decrease the CPU or memory value without selecting the **Allow Power Off** option. When you ran the action where a target object is powered on and where **Memory Hot Plug** is not activated for the target object in vCenter, the action fails.

1. Either activate **Memory Hot Plug** on your target virtual machines in vCenter or select **Allow Power Off** when you run the Set CPU Count, Set Memory, or Set CPU and Memory actions.
2. Check your hot plug limit in vCenter.

**Troubleshooting Set CPU Count or Set Memory with Powered Off Allowed**

A Set CPU Count, Set Memory, or a Set CPU Count and Set Memory action indicates that the action failed in Recent Tasks.

When you run an action that changes the CPU count, the memory, or both, the action fails. It fails even though Power Off Allowed was selected, the virtual machine is running, and the VMware Tools are installed and running.

The virtual machine must shut down the guest operating system before it powers off the virtual machine to make the requested changes. The shutdown process waits 120 seconds for a response from the target virtual machine, and fails without changing the virtual machine.

1. To determine if it has jobs running that are delaying the implementation of the action, check the target virtual machine in vCenter.
2. Retry the action from VCF Operations.

**Troubleshooting Set CPU Count and Memory When Values Not Supported**

If you run the Set CPU Count or Set Memory actions with an unsupported value on a virtual machine, the virtual machine might be left in an unusable state. That outcome requires you to resolve the problem in vCenter.

You cannot power on a virtual machine after you successfully run the Set CPU Count or Set Memory actions. When you review the messages in Recent Tasks for the failed Power On VM action, you see messages stating that the host does not support the new CPU count or new memory value.

Because of the way that vCenter validates changes in the CPU and memory values, you can use the VCF Operations actions to change the value to an unsupported amount. This change can happen when you run the action when the virtual machine is powered off.

If the object was powered on, the task fails, but rolls back any value changes and powers the machine back on. If the object was powered off, the task succeeds and the value is changed in vCenter. However, the target object is left in a state where you cannot power it on using either actions or the vCenter without manually changing the CPU or memory to a supported value.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Control Panel**, and then select the **Recent Tasks** tile.
2. In the task list, locate your failed Power On VM action, and review the messages associated with the task.
3. Look for a message that indicates why the task failed.
   For example, if you ran a Set CPU Count action on a powered off virtual machine to increase the CPU count from 2 to 4, but the host does not support 4 CPUs. The Set CPU tasks reported that it completed successfully in recent tasks. However, when you attempt to power on the virtual machine, the tasks fails. In this example, the message is `Virtual machine requires 4 CPUs to operate, but the host hardware only provides 2.`
4. Click the object name in the Recent Task list.
   The main pane updates to display the object details for the selected object.
5. Click the **Actions** menu on the toolbar and click **Open Virtual Machine in vSphere Client**.
   The vSphere Web Client opens with the virtual machine as the current object.
6. In the vSphere Web Client, click the **Manage** tab and click **VM Hardware**.
7. Click **Edit**.
8. In the Edit Settings dialog box, change the CPU count or memory to a supported value and click **OK**.
   You can now power on the virtual machine from the Web client or from VCF Operations.

**Troubleshooting Set CPU Resources or Set Memory Resources When the Value Is Not Supported**
If you run the Set CPU Resources action with an unsupported value on a virtual machine, the task fails and an error appears in the Recent Task messages.

The Recent Tasks list indicates that a Set CPU Resource or Set Memory Resource action has a state of `Failed`. When you evaluate the Messages list for the selected task, you see a message similar to the following examples.

```
RuntimeFault exception, message:[A specified parameter was not correct.
 spec.cpuAllocation.reservation]
```

```
RuntimeFault exception, message:[A specified parameter was not correct.
 spec.cpuAllocation.limits]
```

You submitted the action to increase or decrease the CPU or memory reservation or limit value with an unsupported value. For example, if you supplied a negative integer other than -1, which sets the value to unlimited, vCenter cannot make the change and the action failed.

Run the action with a supported value.

The supported values for reservation include 0 or a value greater than 0. The supported values for limit include -1, 0, or a value greater than 0.

**Troubleshooting Set CPU Resources or Set Memory Resources When the Value Is Too High**
You run the Set CPU Resources or Set Memory Resources action and the task fails with an error appearing in the Recent Tasks messages. The reason might be that you entered a value that is greater than the value that your vCenter instance supports.

The Recent Tasks list indicates that a Set CPU Resource or Set Memory Resource action has a state of `Failed`. When you evaluate the Messages list for the selected task, you see messages similar to the following examples.

If you are working with Set CPU Resources, the information message is similar to the following example, where 1000000000 is the supplied reservation value.

```
Reconfiguring the Virtual Machine Reservation to:[1000000000] Mhz
```

The error message for this action is similar to this example.

```
RuntimeFault exception, message:[A specified parameter was not correct: reservation]
```

If you are working with Set Memory Resources, the information message is similar to the following example, where 1000000000 is the supplied reservation value.

```
Reconfiguring the Virtual Machine Reservation to:[1000000000] (MB)
```

The error message for this action is similar to this example.

```
RuntimeFault exception, message:[A specified parameter was not correct.
 spec.memoryAllocation.reservation]
```

You submitted the action to change the CPU or memory reservation or limit value to a value greater than the value supported by vCenter, or the submitted reservation value is greater than the limit.

Run the action using a lower value.

**Troubleshooting Set Memory Resources When the Value Is Not Evenly Divisible by 1024**
If you run the Set Memory Resources action with a value that cannot convert from kilobytes to megabytes, the task fails and an error appears in the Recent Task messages.

The Recent Tasks list indicates that a Set Memory Resource action has a state of `Failed`. When you evaluate the Messages list for the selected task, you see a message similar to the following example.

```
Parameter validation;[newLimitKB] failed conversion to (MB, (KB)[2000] not evenly
 divisible by 1024.
```

Because vCenter manages memory reservations and limit values in megabytes, but VCF Operations calculates and reports on memory in kilobytes, you must provide a value in kilobytes that is directly convertible to megabytes. To do that, the value must be evenly divisible by 1024.

Run the action where the reservation and limit values are configured with supported values.

The supported values for reservation include 0 or a value greater than 0 that is evenly divisible by 1024. The supported values for a limit include -1, 0, or a value greater than 0 that is evenly divisible by 1024.

**Troubleshooting Failed Shut Down VM Action Status**
A shutdown VM action task has a `Failed` status in the Recent Task list.

The Shut Down VM action did not run successfully.

The Recent Tasks list indicates that a Shut Down VM action has a task status of `Failed`. When you evaluate the Messages list for the selected job, you see `Failure: Shut down confirmation timeout`.

The shutdown process involves shutting down the guest operating system and powering off the virtual machine. The wait time is 120 seconds to shut down the guest operating system. If the guest operating system does not shut down in this time, the action fails because the shutdown action is not confirmed.

To determine why the guest operating system did not shut down in the allotted time, check its status in vCenter.

**Troubleshooting VMware Tools Not Running for a Shutdown VM Action Status**
A Shutdown VM action task has a `Failed` status in the Recent Task list and the Message indicates that VMware Tools were required.

The Shutdown VM action did not run successfully.

The Recent Tasks list indicates that a Shutdown VM action has a tasks status of `Failed`. When you evaluate the Messages list for the selected job, you see `VMware Tools: Not running (Not installed)`.

The Shutdown VM action requires that VMware Tools is installed and running on the target virtual machines. If you ran the action on more than one object, then VMware Tools was not installed, or installed but not running, on at least one of the virtual machines.

In the vCenter instance that manages the virtual machine that failed to run the action, install and start VMware Tools on the affected virtual machines.

**Troubleshooting Failed Delete Unused Snapshots Action Status**
A Delete Unused Snapshots action task has a `Failed` status in the Recent Task list.

The Delete Unused Snapshots action did not run successfully.

The Recent Tasks list indicates that a Delete Unused Snapshots action has a task status of `Failed`. When you evaluate the Messages list for the selected job, you see this message.

```
Remove snapshot failed, response wait expired after:[120] seconds,
  unable to confirm removal.
```

The delete snapshot process involves waiting for access to datastores. The wait time is 600 seconds to access the datastore and delete the snapshot. If the delete request is not passed to the datastore in that time, the action does not finish the delete snapshot action.

1. To determine if the snapshot was deleted, check its status in vCenter .
2. If it was not, submit the delete snapshot request at a different time.

# Managing Inventory

You can configure, discover, and manage objects in your environment. You can also view a detailed list of the inventory in your VCF Operations environment where the objects are grouped logically.

## Enhanced Search Capability

The search function on the top supports locating named objects, dashboards, alerts, and so on, in the system. The search function attempts to match or partially match any string you enter; additional capabilities help you to go swiftly to the item you want.

### Where you Find Search

The search function appears on all the pages of VCF Operations in the top menu.

### How Search Works

You start your search by typing in the search bar. VCF Operations displays matching categories or objects.

The search function supports several common categories you can employ to find the item you seek quickly, as follows:

- Object
- Metric
- Feature
- Dashboard
- Report
- View
- Alert definition
- Symptom definition
- Recommendation
- Notification
- I.P.
- Super metric

What this means is that in addition to entering a traditional search phrase, for example, a simple string - "VM" - you can also enter one of the listed categories followed by a string or a name. You can then search for objects within the category. For the Object, View and Dashboard categories, the system displays the object in view mode.

If you want quickly to locate a specific dashboard, for example, start typing "dash..." into the search field. The system offers the search term Dashboards. Select the term using the cursor and then enter the dashboard name or part of the name and press Enter. The system finds the dashboard you want, with editing functions available.

Similarly, you can type "alert" or simply "a" in the search field and the system offers Alert Definition. Select the term and enter part of an alert message, for example, "unbalanced." The system returns the alert, "Cluster has an unbalanced workload," presented in the Alert Definition Workspace where you can edit it.

> **Note:**
> You can type virtual machine in the search bar to list all the virtual machines associated with the host.

**Feature Search**

You can now search for a feature in VCF Operations. Select **Feature** from the drop down list and type the feature name. You can type the feature name or simply part of the feature name. For example, you can type 'licenses' or simply 'li' in the search field. In addition to the feature name, the navigation path to the feature is also displayed.

> **Note:**
>
> Feature names are available for search based on license and user permissions.

**Extend User Search for Alert Assignment**

In VCF Operations now you can search for a user and assign alerts to that user using the following filter options.

- User name
- First Name
- Last Name
- Email Address

VCF Operations displays the details of the searched user in search results, you can use the details to assign the alert to specific user.

**Metric Search**

You can create a search query using a metric, property, object type name, super metric, or instance metric name. Enter the metric name or select the metric, property, or object type from the list of suggestions. The suggestions also display a list of recent searches that match the text you enter in the search bar. You can also delete recent searches. Create a simple query using the metric name and the object type or add conditions and operators to your query to build a more complex query depending on your requirement. Conditions and operators allow you to narrow down the search results. Once you have created the query, click enter to view the search results. The search results are based on the values you select. For more information on how to create queries, see Searching for Metrics, Properties, or Object Types Using Queries.

## Searching for Metrics, Properties, or Object Types Using Queries

The search queries will run across your entire deployment and find all types of objects based on the specified search terms used in a search query. Additionally, VCF Operations provides suggestions to build the search queries, which include recent searches that match the typed text in the global search bar. You can also find specific types of objects using conditions in the search query.

You can create a simple search query starting with a metric, property, or object type, or you can build a more complex query using different conditions to find all types of entities in VCF Operations. Metric queries can be divided into two parts, the metric search query and the metric search result. After you create a metric search query, click **Enter** to view the Metric Search Results page.

You can also use instance metrics and super metrics to search for objects.

1. In the VCF Operations navigation bar at the top, click the **Search** bar and then select **Metric**.

   > **Note:**
   > When you click the cursor in the search bar, a list of suggestions with the metric and property names and the object types appear. You can select a metric, property, or object type from this list. If you hover over the metric and property names you can view the name of the object types that the metric or property belongs to. If you enter an entity in the search bar, the suggestions change and display options based on your entry. You can start with a metric name and then select the object type it belongs to, or start with an object type and add conditions.

2. Create a simple query with a metric or property name. For example, enter `CPU|Usage %` in the search bar.

   If you start a metric search query with a metric name, you must always mention the object type it belongs to.

   > **Note:**
   > If the selected metric belongs to a single object type, then the object type will be selected by default.

3. The object types change based on the metric you enter. Select `Virtual Machine` as the object type.

   A simple metric search query is created as follows: `CPU|Usage % of Virtual Machine`. A green banner with the `Press enter to see the results or continue expanding the query.` message appears.

4. Optional: Click **Enter** to view the results of this simple search query or continue to expand your search query to narrow down the search results.

   **Note:**
   If your query is incomplete, has a syntax error, exceeds the character limit of 300, or has more than five different metric names, the search query will not work. In such cases a red banner appears explaining the issue. For example, in case of a syntax error, the `The query contains syntax error(s). Please modify it to get suggestions.` message appears.

5. The metric search query allows you to search for objects based on the conditions you use. Expand the search query with the **where** and **childOf** conditions.

   a) Add a **where** condition to filter the search results. You can combine the where conditions with logical operators to form complex metric search queries.

   **Note:**
   For string metrics the condition values are case insensitive.

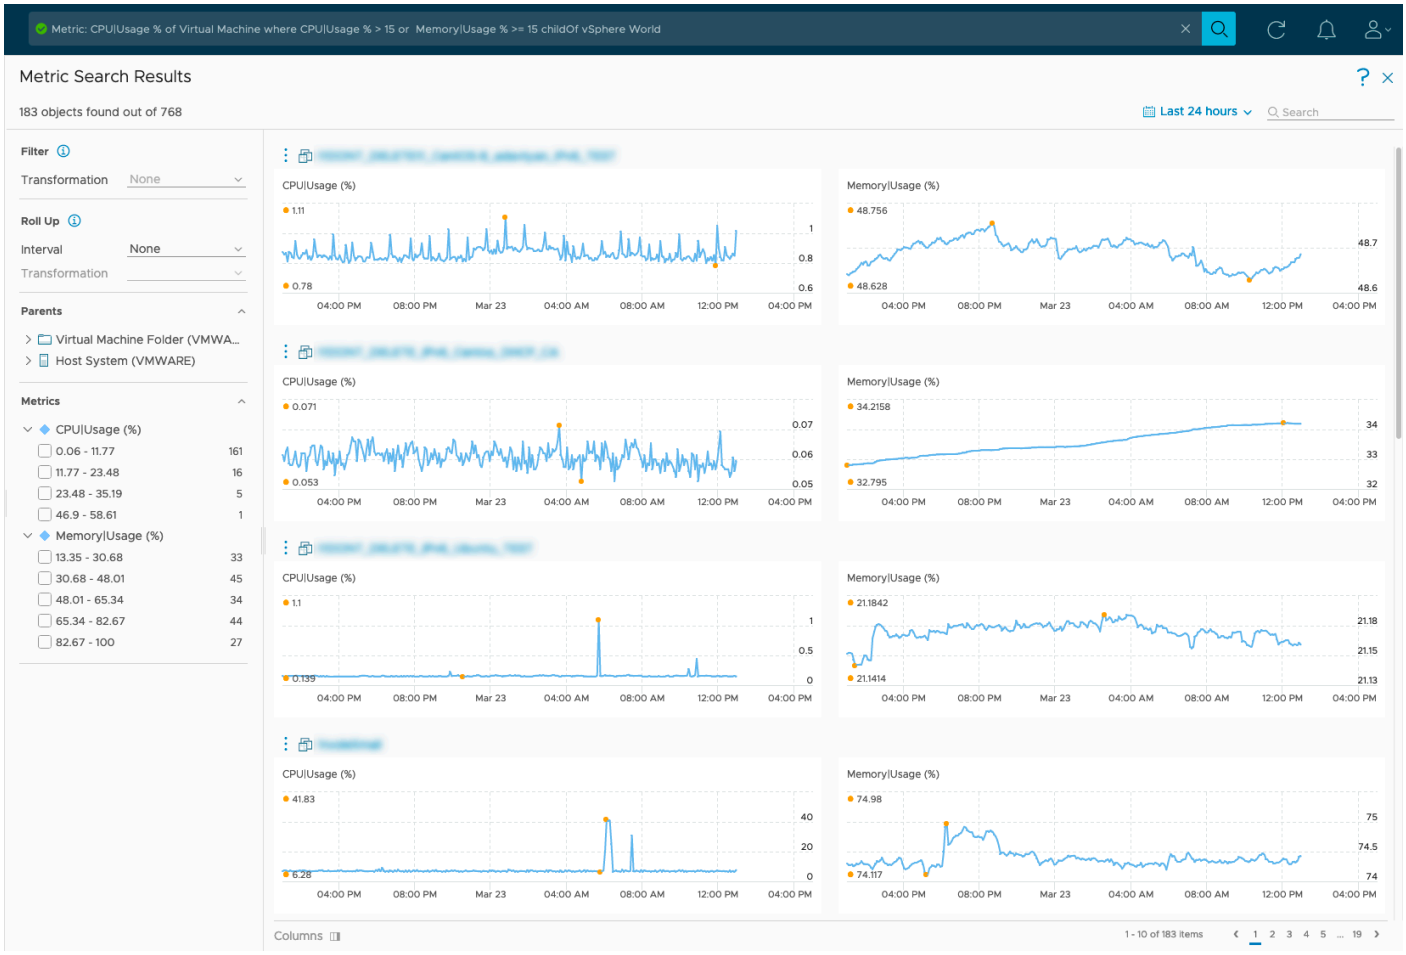
| Operator | Examples |
|---|---|
| **Numeric Operators** | |
| > | `CPU\|Usage % of Virtual Machine where CPU\|Usage % > 15%` |
| >= | `CPU\|Usage % of Virtual Machine where CPU\|Usage % >= 15` |
| < | `CPU\|Usage % of Virtual Machine where CPU\|Usage % < 15` |
| <= | `CPU\|Usage % of Virtual Machine where CPU\|Usage % <= 15%` |
| = | `CPU\|Usage % of Virtual Machine where CPU\|Usage % = 15` |
| != | `CPU\|Usage % of Virtual Machine where CPU\|Usage % != 15` |
| + | `CPU\|Usage % of Virtual Machine where (CPU\|Usage % + Memory\|Usage %) > 15` |
| - | `CPU\|Usage % of Virtual Machine where (CPU\|Usage % - Memory\|Usage %) > 15` |
| * | `CPU\|Usage % of Virtual Machine where (CPU\|Usage % * Memory\|Usage %) > 15` |
| / | `CPU\|Usage % of Virtual Machine where (CPU\|Usage % + Memory\|Usage %)/2 > 15` |
| and | `CPU\|Usage % of Virtual Machine where CPU\|Usage % > 15 and Memory\|Usage % > 15` |
| or | `CPU\|Usage % of Virtual Machine where CPU\|Usage % > 15 or Memory\|Usage % > 15` |
| **String Operators** | |

| Operator | Examples |
| --- | --- |
| equals | `CPU\|Demand MHz of Virtual Machine where Configuration\|Name equals 'Centos'` |
| not equals | `CPU\|Demand MHz of Virtual Machine where Configuration\|Name notEquals 'Centos'` |
| contains | `CPU\|Demand MHz of Virtual Machine where Configuration\|Name contains 'Centos'` |
| notContains | `CPU\|Demand MHz of Virtual Machine where Configuration\|Name notContains 'Centos'` |
| startsWith | `CPU\|Demand MHz of Virtual Machine where Configuration\|Name startsWith 'Centos'` |
| notStartsWith | `CPU\|Demand MHz of Virtual Machine where Configuration\|Name notStartsWith 'Centos'` |

b) Use the **childOf** condition at the end of your query to select an ancestor of the object type to further narrow down your search results. Select the object name, for example, select `vSphere World`.

A complex search query is created as follows: `CPU|Usage % of Virtual Machine where CPU|Usage % > 15 or Memory|Usage % > 15 childOf vSphere World`

6. Click **Enter** to view the metric search results.



The search result is displayed on the Metric Search Results page.

7. The metric search results page displays the total number of objects that match the query. You can use the filter options on this page to further drill down the results and find the required information.

| Option | Description |
|---|---|
| Filter: Transformation | The Transformation filter applies to the actual query and not the results as it applies to objects before the search query runs and cannot be used on the results.<br>Determines what calculation method is applied to the raw data. You can convert the metric values of the search results using the transformation option and also select the type of transformation:<br>• Minimum. The minimum value of the metric over the selected time range.<br>• Maximum. The maximum value of the metric over the selected time range.<br>• Average. The mean of all the metric values over the selected time range.<br>• Sum. The sum of the metric values over the selected time range.<br>• First. The first metric value for the selected time range.<br>• Last. The last value of a metric within the selected time range.<br>• Current. The last available value of a metric if it was last updated not before five collection cycles were complete, otherwise, it is null.<br>**Note:**<br>This option is available only if there is a where condition and the number of objects for the mentioned object type do not exceed the limit of 200 for not more than one month. |
| Roll Up | The roll up filter is used to change data visualization based on the selected time interval and transformation. You can select one of the available options ranging from hour, day, week, month, quarter, or year. For example, if you select Hour as the interval and the Maximum as the transformation, then the system displays maximum values for each one-hour interval. |
| Parents | The parent objects grouped by type for the found objects that the metrics in the query belong to. You can use this option to further narrow down the results. |
| Metric | Displays the metrics value distribution. The metric values are divided into 5 ranges and the number of objects which have the metric lying in that range is available. |
| Time Settings | Use the time settings to select the time range for the query.<br>The number of objects based on metrics in the selected time range is also displayed. You can select a time range to view the information. You can set a time range for a past period or set a future date for the end of the time period. |
| Page Navigation | The page navigation option appears when the results resource count exceeds 10. Use the page navigation to continue viewing search results displayed on the next pages. |
| Columns | If the query contains more than two metrics, you can view the search results of two metrics at a time. Use the columns icon to select which two metrics search results are displayed. |

To further troubleshoot objects, click the vertical ellipsis and select troubleshoot to go to the Workbench page. For more information, see Starting the Troubleshooting Workbench.

# Configuring Objects

Using the power of object management - including metrics and alerts - you can monitor objects, applications, and systems that must stay up and running. Some metrics and alerts are prepackaged into dashboards and policies; others you combine into custom tools

VCF Operations discovers objects in your environment and makes them available to you. With the information that VCF Operations provides, you can quickly access and configure any object. For example, you can determine if a datastore is connected or providing data, or you can power on a virtual machine.

## Object Discovery

Its ability to monitor and collect data on objects in your systems environment makes VCF Operations a critical tool in maintaining system uptime and ensuring ongoing good health for all system resources from virtual machines to applications to storage - across physical, virtual, and cloud infrastructures.

Following are examples of objects that can be monitored.

- vCenter
- Virtual machines
- Servers/hosts
- Compute resources
- Resource pools
- Data centers
- Storage components
- Switches
- Port groups
- Datastores

### Adapters – Key to Object Discovery

VCF Operations collects data and metrics from objects using adapters, that are the central components of management packs. You can customize adapter instances for your virtual environment using cloud accounts and other accounts. VCF Operations uses cloud accounts to manage the communication and integration with other products, applications, and functions.

- Cloud Accounts - You can configure cloud adapter instances and collect data from cloud solutions that are already installed in your cloud environment from the cloud accounts page.
- Other Accounts - You can view and configure native management packs and other solutions that are already installed and configure adapter instances from the other accounts page.
- Repository - You can activate or deactivate native management packs and add or upgrade other management packs from the Repository page.

The screenshot displays the list of available solutions in VCF Operations . You must first Activate the solution before adding and configuring the accounts.

For complete information on configuring management packs and adapters, see Integrating Data Sources with VCF Operations

When you create a new adapter instance, it begins discovering and collecting data from the objects designated by the adapter, and notes the relationships between them. Now you can begin to manage your objects.

### Workload Management Inventory Objects

VCF Operations discovers the following workload management objects and their child objects using the vCenter adapter:

- vSphere Kubernetes

- vSphere Pods
- VSphere Namespace

Clusters activated with vSphere IaaS control plane are called Supervisor Clusters. Kubernetes control plane is created inside the hypervisor layer. This layer contains specific objects that enable the capability to run Kubernetes workloads within ESX. After a Supervisor is created, vSphere Namespaces can be created within the Supervisor. A vSphere Namespace sets the resource boundaries where vSphere Pods, VMs, and VKS clusters can run.

> **Note:**
> If a Supervisor Cluster spans multiple Compute Clusters, a Namespaces resource will be created for each Compute Cluster Resource and related to the Supervisor Cluster.

To understand the vSphere Tanzu Kubernetes architecture, see the *VMware vSphere with Tanzu* product documentation.

Workload management objects are excluded from the following workflows:

- Compliance
- Reclaim
- Rightsizing
- Workload optimization

## About Objects

Objects are the structural components of your mission-critical IT applications: virtual machines, datastores, virtual switches and port groups are examples of objects.

Because downtime equals cost - in unused resources and lost business opportunities - it's crucial that you successfully identify, monitor and track objects in your environment. The goal is to proactively isolate, troubleshoot and correct problems even before users are aware that anything is wrong.

When a user actually reports an issue, the solution should be quick and comprehensive.

For a complete list of objects that can be defined in VCF Operations refer to Object Discovery.

VCF Operations gives you visibility into objects including applications, storage and networks across physical, virtual and cloud infrastructures through a single interface that relates performance information to positive or negative events in the environment.

### Managing Objects

When you monitor a large infrastructure, the number of objects and corresponding metrics in VCF Operations grows rapidly, especially as you add solutions that extend dynamic monitoring and alerts to more parts of your infrastructure. VCF Operations gives you ample tools to stay abreast of events and issues.

### Adding Objects and Configuring Object Relationships

VCF Operations automatically discovers objects and their relationships once you create an adapter instance. You have the added ability to manually add any objects that you want monitored and to configure object relationships using abstract concepts rather than the connections recorded by VCF Operations. Where VCF Operations might discover the cla ssic parent-child relationships between objects, you can create relationships between objects that might not normally be related. For example, you could configure all the datastores supporting a company department to be related.

When objects are related, a problem with one object appears as an anomaly on related objects. So object relationships can help you to identify problems in your environment quickly. The object relationships that you create are called custom groups.

### Custom Groups

To create an automated management system you need some way to organize objects so that you can quickly gain insights. You can achieve a high level of automation using custom groups. You have multiple options for tailoring group attributes to support your monitoring strategy.

For example, you can designate a group either to be static or to be updated automatically with membership criteria that you designate. Consider a non-static group of all virtual machines that are powered on and have OS type Linux. When you power on a new Linux VM, it is automatically added to the group and the policy is applied.

For additional flexibility, you can also specify individual objects to be always included or excluded from a given custom group. Or you can have a different set of alerts and capacity calculations for your production environment versus your testing environments.

**Managing Applications**

VCF Operations allows you to create containers or objects that can contain a group of virtual machines or other objects in different structural tiers. This new application can then be managed as a single object, and have health badges and alarms aggregated from the child objects of the group.

For example, the system administrator of an online training system might request that you monitor components in the Web, application and database tiers of the training environment. You build an application that groups related training objects together in each tier. If a problem occurs with one of the objects, it is highlighted in the application display and you can investigate the source of the problem

**The Power of Object Management**

Using the power of object management, including metrics and alerts - some prepackaged into dashboards and policies, others that you combine into custom monitoring tools - you'll keep a close watch on the objects, applications and systems that must stay up and running.

## Managing Objects in Your Environment

An object is the individual managed item in your environment for which VCF Operations collects data, such as a router, switch, database, virtual machine, host, and vCenter instances.

The system requires specific information about each object. When you configure an adapter instance, VCF Operations performs object discovery to start collecting data from the objects with which the adapter communicates.

An object can be a single entity, such as a database, or a container that holds other objects. For example, if you have multiple Web servers, you can define a single object for each Web server and define a separate container object to hold all of the Web server objects. Groups and applications are types of containers.

Categorize your objects using tags, so that you can easily find, group, or filter them later. A tag type can have multiple tag values. You or VCF Operations assigns objects to tag values. When you select a tag value, VCF Operations displays the objects associated with that tag. For example, if a tag type is Lifecycle and tag values are Development, Test, Pre-production, and Production, you might assign virtual machine objects VM1, VM2, or VM3 in your environment to one or more of these tag values, depending on the virtual machine function.

### Adding an Object to Your Environment

You might want to add an object by providing its information to VCF Operations. For example, some solutions cannot discover all the objects that might be monitored. For these solutions, you must either use manual discovery or manually add the object.

Verify that an adapter is present for the object you plan to add. See Integrating Data Sources with VCF Operations.

Verify that an adapter is present for the object you plan to add. See the Getting Started with *VCF Operations* .

> **Note:**
> Objects added to VCF Operations via API will require an OSI license per object.

When you add an individual object, you provide specific information about it, including the kind of adapter to use to make the connection and the connection method. For example, a vSAN adapter does not know the location of the vSAN devices that you want to monitor.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile.
2. From the **Objects** tab, on the toolbar, click the plus sign.
3. Use the topic menus to reveal all fields and provide the required information.

| Option | Description |
|---|---|
| **Display name** | Enter a name for the object. For example, enter `vSAN-Host1`. |
| **Description** | Enter any description. For example, enter `vSAN-Host monitored with vSAN adapter` |
| **Adapter type** | Select an adapter type. For example, select **vSAN Adapter**. |
| **Adapter instance** | Select an adapter instance. |
| **Object type** | Select an object type. For a vSAN adapter, you might select vSAN-Host. When you select the object type, the dialog box selections change to include information you provide so that VCF Operations connect with the selected object type. |
| **Host IP address** | Enter the host IP. For example, enter the IP address of vSAN-Host1. |
| **Port number** | Accept the default port number or enter a new value. |
| **Credential** | Select the Credential, or click the plus sign to add new login credentials for the object. |
| **Collection interval** | Enter the collection interval, in minutes. For example, if you expect the host to generate performance data every 5 minutes, set the collection interval to 5 minutes. |
| **Dynamic Thresholding.** | Accept the default, Yes. |

4. Click **OK** to add the object.

vSAN-Host1 appears in the Inventory as a host object type for the vSAN adapter type.
When you add an individual object, VCF Operations does not begin collecting metrics for the object until you turn on data collection. See Inventory : List of Objects.

For each new object, VCF Operations assigns tag values for its collector and its object type. Sometimes, you might want to assign other tags. See Creating and Assigning Tags.

For each new object, VCF Operations assigns tag values for its collector and its object type. Sometimes, you might want to assign other tags.

**Configuring Object Relationships**
VCF Operations shows the relationship between objects in your environment. Most relationships are automatically formed when the objects are discovered by an installed adapter. In addition, you can use VCF Operations to create relationships between objects that might not normally be related.

Objects are related physically, logically, or structurally.

- Physical relationships represent how objects connect in the physical world. For example, virtual machines running on a host are physically related.
- Logical relationships represent business silos. For example, all the storage objects in an environment are related to one another.
- Structural relationships represent a business value. For example, all the virtual machines that support a database are structurally related.

Solutions use adapters to monitor the objects in your environment so that physical relationship changes are reflected in VCF Operations. To maintain logical or structural relationships, you can use VCF Operations to define the object relationships. When objects are related, a problem with one object appears as an influence on related objects. So object relationships can help you to identify problems in your environment quickly.

Apart from the parent-child relationship, you can also define new relationships in VCF Operations. The relationship between objects in your environment can be one-to-many, many-to-one, or one-one, the relationship can be defined in horizontal , vertical, or diagonal levels.

### Creating and Assigning Tags

A large enterprise can have thousands of objects defined in VCF Operations. Creating object tags and tag values makes it easier to find objects and metrics. With object tags, you select the tag value assigned to an object and view the list of objects that are associated with that tag value.

A tag is a type of information, for example, Adapter Types. Adapter Types is a predefined tag. Tag values are individual instances of that type of information. For example, when the system discovers objects using the vCenter Adapter, it assigns all the objects to the vCenter Adapter tag value under the Adapter Types tag.

You can assign any number of objects to each tag value, and you can assign a single object to tag values under any number of tags. You typically look for an object by looking under its adapter type, its object type, and possibly other tags.

If an object tag is locked, you cannot add objects to it. VCF Operations maintains locked object tags.

#### Predefined Object Tags

VCF Operations includes several predefined object tags. It creates values for most of these tags and assigns objects to the values.

For example, when you add an object, the system assigns it to the tag value for the collector it uses and the kind of object that it is. VCF Operations creates tag values if they do not already exist.

If a predefined tag has no values, there is no object of that tag type. For example, if no applications are defined, the applications tag has no tag values.

Each tag value appears with the number of objects that have that tag. Tag values that have no objects appear with the value zero. You cannot delete the predefined tags or tag values.

**Table 1239: Predefined Tags**

| Tag | Description |
|---|---|
| Collectors (Full Set) | Each defined collector is a tag value. Each object is assigned to the tag value for the collector that it uses when you add the object to VCF Operations. The default collector is VCF Operations Collector. |
| Applications (Full Set) | Each defined application is a tag value. When you add a tier to an application, or an object to a tier in an application, the tier is assigned to that tag value. |
| Maintenance Schedules (Full Set) | Each defined maintenance schedule is a tag value, and objects are assigned to the value when you give them a schedule by adding or editing them. |
| Adapter Types | Each adapter type is a tag value, and each object that uses that adapter type is given the tag value. |
| Adapter Instances | Each adapter instance is a tag value, and each object is assigned the tag value for the adapter instance or instances through which its metrics are collected. |
| Object Types | Each type of object is a tag value, and each object is assigned to the tag value for its type when you add the object. |
| Recently Added Objects | The last day, seven days, 10 days, and 30 days have tag values. Objects have this tag value as long as the tag value applies to them. |
| Object Statuses | Tag value assigned to objects that are not receiving data. |
| Collection States | Tag value assigned to indicate the object collection state, such as collecting or not collecting. |

| Tag | Description |
|---|---|
| Health Ranges | Good (green), Warning (yellow), Immediate (orange), Critical (red), and Unknown (blue) health statuses have tag values. Each object is assigned the value for its current health status. |
| Entire Enterprise | The only tag value is Entire Enterprise Applications. This tag value is assigned to each application. |
| Licensing | Tag values are License Groups found under **Subscriptions** > **Legacy Licenses** > **License Groups**. Objects are assigned to the license groups during VCF Operations installation. |
| Untag | Drag an object to this tag to delete the tag assignment. |

### Add an Object Tag and Assign Objects to the Tag

An object tag is a type of information, and a tag value is an individual instance of that type of information. If the predefined object tags do not meet your needs, you can create your own object tags to categorize and manage objects in your environment. For example, you can add a tag for cloud objects and add tag values for different cloud names. Then you can assign objects to the cloud name.

Become familiar with the predefined object tags.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile.
2. Click the **Manage Tags** icon above the list of tags.
3. Click the **Add New Tag** icon to add a new row and type the name of the tag in the row.
   For example, type `Cloud Objects` and click **Update**.
4. With the new tag selected, click the **Add New Tag Value** icon to add a new row and type the name of the value in the row.
   For example, type `Video Cloud` and click **Update**.
5. Click **OK** to add the tag.
6. Click the tag to which you want to add objects to display the list of object tag values.
   For example, click **Cloud Objects** to display the Video Cloud object tag value.
7. Drag objects from the list in the right pane of the Inventory onto the tag value name.
   You can press Ctrl+click to select multiple individual objects or Shift+click to select a range of objects.
   For example, if you want to assign data centers that are connected through the vCenter Adapter, type `vCenter` in the search filter and select the data center objects to add.

### Use a Tag to Find an Object

The quickest way to find an object in VCF Operations is to use tags. Using tags is more efficient than searching through the entire object list.

Tag values that can also be tags are Applications and Object Types. For example, the Object Types tag has values for each object that is in VCF Operations, such as Virtual Machine, which includes all the virtual machine objects in your environment. Each of these virtual machines is also a tag value for the Virtual Machine tag. You can expand the tag value list to select the value for which you want to see objects.

1. In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile.
2. In the tag list in the center pane, click a tag for an object with an assigned value.
   When you click a tag, the list of values expands under the tag. The number of objects that is associated with each value appears next to the tag value.
   A plus sign next to a tag value indicates that the value is also a tag and that it contains other tag values. You can click the plus sign to see the subvalues.

3. Select the tag value.

   The objects that have that tag value appear in the pane on the right. If you select multiple tag values, the objects in the list depend on the values that you select.

| Tag Value Selection | Objects Displayed |
|---|---|
| More than one value for the same tag | The list includes objects that have either value. For example, if you select two values of the Object Types tag, such as Data Center and Host System, the list shows objects that have either value. |
| Values for two or more different tags | The list includes only objects that have all of the selected values. For example, if you select two values of the Object Types tag, such as Data Center and Host System, and you also select an adapter instance such as vC-1 of the vCenter Adapter instance tag, only Data Center or Host System objects associated with vC-1 appear in the list. Data Center or Host System objects associated with other adapter instances do not appear in the list, nor do objects that are not Data Center or Host System objects. |

4. Select the object from the list.

**Manage Object Tags Workspace**

A large enterprise can have thousands of objects. When objects are assigned to a tag, and you choose to display objects with that tag value, the objects are easier to find on the Inventory list.

**Where You Find Manage Object Tags**

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile.

Click the **Manage Tags** icon above the list of tags in the middle pane.

**Manage Object Tags Options**

The Manage Object Tags screen appears with previously created tags listed. In the left pane, you add tags. In the right pane, you add tag values.

- Click **Add a New Tag** and type a new tag name, or select a tag to delete.
- For the selected tag, click **Add a New Tag Value** and type a new tag value name, or select a tag value to delete.
- For the GEO Location tag, you can add and delete a new tag value in the left pane.

**Manage Object Type Tags Workspace**

Every object in your environment is of a particular object type. You use Manage Object Type Tags to control the object type tags displayed.

**How Manage Object Type Tags Works**

For every adapter instance installed, VCF Operations discovers objects in your environment and starts collecting data from those objects.

**Where You Find Manage Object Type Tags**

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile. Click the **Manage Object Type Tags** icon above the list of tags.

**Manage Object Type Tags Options**

Depending on the number of adapters installed , there may be hundreds of object type tags. The Manage Object Type Tags options allow you to turn on or off the tags listed.

- Type a filter word to show the object type tags with the word.
- Name lists all the object type tags.
- To toggle the display of an object type tag, select the check box in the Show Tag column of its row.

**Inventory : List of Objects**
VCF Operations discovers objects in your environment for each adapter instance and lists them. From the complete list of all the objects in your environment, you can quickly access and configure any object. For example, you can check if a datastore is connected or providing data, or you can power on a virtual machine.

## How the List Works

Objects appear in a data grid. To find a particular object, you can sort a column in the grid or search for a filter word. In addition to sorting and searching, assigning objects to object tags makes it easier to find objects and metrics.

## Where You Find the List

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile. The system lists all the objects in your environment.

## Inventory List Options

The center pane includes object tag options. The **Object** tab in the right pane includes toolbar options for all of the objects in your environment.

**Table 1240: Object Tag Toolbar Options from the Center Pane**

| Option | Description |
|---|---|
| Collapse all | Closes all the tag group selections. |
| Deselect All | Tags remain selected until deselected. Use this option to deselect all tags. |
| Manage Tags | Add a tag or tag value. See Manage Object Tags Workspace. |
| Manage Object Type Tags | There might be many object type tags. Use this option to choose the object type tags to display. See Manage Object Type Tags Workspace. |

**Note:**
If there are more than ten objects under an object tag in the centre pane, you can search for a descendant object using the Search option. If there are more than five hundred objects in a section, use the **View More** button under the last object that is displayed, to view the rest of the objects. Use the **Type to see more** button to find objects if there are more than one thousand objects.

Use the toolbar options to manage objects from the **Objects** Tab.

- Filter options limit the list to objects matching the filter. Filter options include ID, Name, Description, Maintenance Schedule, Adapter Type, Object Type, and Identifiers.
- Select the object to manage from the list. If an object tag is selected, only objects of the selected tag value are listed. Column headings help you to identify the object. See Object List Widget.

**Table 1241: Inventory Toolbar Options from the Object Tab**

| Option | Description |
|---|---|
| Action | Perform an action on the selected object. Available actions depend on the object type. For example, Power on VM applies to the selected virtual machine. See Actions in VCF Operations. |
| Open in external application | If an adapter includes the ability to link to another application for information about the object, click the button to access a link to the application. For example, Open Virtual Machine in a vSphere Client or Search for VM logs in Log management. |

| Option | Description |
|---|---|
| Edit object | Edit the selected object. For example, add or change the maintenance schedule for a virtual machine. If multiple objects of the same type are selected, common identifiers for the object type are editable. For example, change the VM entity name of multiple datastores with a single edit. See Manage Objects Workspace. |
| Add object | VCF Operations discovers objects for most adapters. For adapters that do not support autodiscovery for all objects, the objects are manually added. See Manage Objects Workspace. |
| Discover Objects | Perform an IP scan to discover objects associated with a particular adapter. See Discover Objects Workspace. |
| Delete object | Remove the object from the list. |
| Start maintenance | Take the object offline for maintenance. See Manage Maintenance Schedules for Your Object Workspace. |
| End maintenance | Terminate the maintenance period and put the selected object back online. |
| Clear Selections | Clear all object selections. |
| Select All | Select all objects displayed. |
| Show Detail | Display the **Summary** tab of the selected object. |
| Per page | The number of objects to list per page. |

Manage Objects Workspace

To collect data from an object, you might need to add an object or edit an existing object in your environment. For example, you might need to add objects for an adapter that does not support autodiscovery, or change the maintenance schedule of an existing object.

### Where You Find Manage Objects

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile. Click the plus sign to add an object or the edit icon to edit the selected object.

Items that appear in the window depend on the object that you are editing. Not all options can be changed.

**Table 1242: Manage Objects Add or Edit Options**

| Options | Description |
|---|---|
| Display name | Name of the object. Use only letters and numbers. Do not use nonalphanumeric characters or spaces. |
| Description | (Optional) For informational purposes only. |
| Adapter Type | If you are editing an object, you cannot change the adapter type. |
| Adapter Instance | If you are editing an object, you cannot change the adapter instance. |
| Object Type | If you are editing an object, you cannot change the object type. More configuration options might appear, depending on the object type. |
| Dynamic Thresholding | On by default, to activate dynamic thresholding and early warning smart alerts. See VCF Operations Dynamic Thresholds |

Discover Objects Workspace

If VCF Operations does not discover objects after an adapter instance is configured, use manual discovery. Discovering objects is more efficient than adding objects individually.

> **Note:**
> You use discovery to define objects for embedded adapters. VCF Operations discovers objects that use external adapters.

### Where You Find Discover Objects

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile.

### Discover Objects

The Discoveries section of the `describe.xml` file for the adapter might include parameters for discovery information. The `describe.xml` file is in the `conf` sub folder of the adapter, for example `xyz_adapter3/conf/describe.xml`.

| Options | Description |
|---|---|
| Collector | Collector that VCF Operations uses to discover objects. Only the VCF Operations Collector is added during installation. |
| Adapter Type | Adapter type for the objects to discover. |
| Adapter Instance | Adapter instance of the selected adapter type. |
| Discovery Info | Selection depends on the adapter type. For example, for a vCenter adapter, the Discovery Info selection adds an option to discover objects of a particular object type. |
| Only New Objects | On by default, to omit objects that are already discovered. |

### Object Type

Based on your selection of Adapter Type, Adapter Instance, and Discovery Info, the Object Type values change. The available adapter types are NSX-T, vCenter Adapter, vSAN Adapter.

NSX-T Object Types:

- Edge Cluster
- Firewall Section
- Groups
- Load Balancer Pool
- Load Balancer Service
- Load Balancer Virtual Server
- Logical Router
- Logical Switch
- Router Service
- Transport Node
- Transport Zone

vCenter Object Types:

- Cluster Compute Resource
- Datastore
- Datacenter
- Folder
- Host System
- Resource Pool
- Virtual Machine

vSAN Object Types:

- Cache Disk
- Capacity Disk
- vSAN Cluster
- vSAN Disk Group
- vSAN Fault Domain
- vSAN Witness Host

Discovery Results List

When you use the Discover Objects feature to manually discover objects in your environment, VCF Operations lists the objects of the specified object type. You can choose the objects to monitor.

**Where You Find Discovery Results**

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile.

After you make selections in the Discover Objects Workspace, click **OK**. With the default setting, VCF Operations displays only newly discovered objects. See Discover Objects Workspace.

**Table 1243: Object Types**

| Options | Description |
|---|---|
| Object Type | Discovered object types of the Object Type selected on the Discover Objects Workspace. |
| Object Count | Number of objects of the object type. |
| Import | When selected, imports the object type. Option is active and selectable for newly discovered object types. |
| Collect | When selected, imports the object type and starts collecting data. Option is active and selectable for newly discovered object types. |
| Credential | If the object type requires a login credential to collect data from the object., the value is **True**. |

Double-click the Object Type to display a list of objects to monitor.

**Table 1244: Objects**

| Options | Description |
|---|---|
| Object | Objects of the selected type that exist in the environment for the adapter. For example, the vCenter adapter discovers objects in the vCenter system. |
| Import | When selected, imports the object but does not start collecting data. Option is active and selectable for newly discovered objects that do not exist in the VCF Operations environment . |
| Exists | Indicates that the object exists in the VCF Operations environment. |
| Collect | When selected, imports the object and starts collecting data. Option is active and selectable for newly discovered objects that do not exist in the VCF Operations environment. |

Manage Maintenance Schedules for Your Object Workspace

You use maintenance mode to take an object offline. Many objects in your environment might be intentionally taken offline. For example, you might deactivate a server to update software. If VCF Operations collects metrics when the object is offline, it might generate incorrect alerts that affect the data for the object's health. When an object is in maintenance mode, VCF Operations does not collect metrics from the object and does not generate alerts for it.

### How Maintenance Schedules Work

If an object undergoes maintenance at fixed intervals, you can create a maintenance schedule and assign it to the object. For example, you can put an object into maintenance mode from midnight until 3 a.m. every Tuesday night. You can also manually put an object in maintenance mode, either indefinitely or for a specified period of time. These methods are not mutually exclusive. You can put an object in maintenance mode or take it out of maintenance mode, even if it has an assigned maintenance schedule.

### Where You Find Manage Maintenance Schedules

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile. Click **Start Maintenance** from the tool bar in the **Objects** tab.

**Table 1245: Manage Maintenance Schedules Options**

| Options | Description |
|---|---|
| I will come back and end maintenance myself. | Maintenance mode starts for the selected object when you click **OK**. You must manually end maintenance mode for this object. |
| End maintenance in | Type the number of minutes that the object is in maintenance mode. |
| End maintenance on | Click the calendar icon, and select the date that maintenance mode ends. |

Define Custom Property Workspace

In VCF Operations, you can define custom properties to collect and store operational data related to different objects. The custom property can be either a string or a numeric. You can assign custom properties to any subset of objects irrespective of the adapter kind and resource kind. You can use a mouse click, search filter, or a tag selector to select the correct object.

### Where You Find Add/Edit Custom Property

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Inventory Management** tile. Click **Add/Edit Custom Property** from the tool bar in the **Objects** tab.

**Table 1246: Add/Edit Custom Property**

| Options | Description |
|---|---|
| Property Name | Select or enter a property name. |
| Type | Select the property type from the drop-down menu. |
| Value | Enter a value for the property. |

You can assign the custom properties defined in this page to the Custom Object Groups and New Groups.

For more information, see Custom Object Groups Workspace to Create a New Group.

## Managing Custom Object Groups in VCF Operations

A custom object group is a container that includes one or more objects. VCF Operations uses custom groups to collect data from the objects in the group, and report on the data collected.

### Why Use Custom Object Groups?

You use groups to categorize your objects and have the system collect data from the groups of objects and display the results in dashboards and views according to the way you define the data to appear.

You can create static groups of objects, or dynamic groups with criteria that determine group membership as VCF Operations discovers and collects data from new objects added to the environment.

VCF Operations provides commonly used object group types, such as World, Environment, and Licensing. The system uses the object group types to categorize groups of objects. You assign a group type to each group so that you can categorize and organize the groups of objects that you create.

### Types of Custom Object Groups

When you create custom groups, you can use rules to apply dynamic membership of objects to the group, or you can manually add the objects to the group. When you add an adapter, the groups associated with the adapter become available in VCF Operations.

- Dynamic group membership. To dynamically update the membership of objects in a group, define rules when you create a group. VCF Operations adds objects to the group based on the criteria that you define.
- Mixed membership, which includes dynamic and manual.
- Manual group membership. From the inventory of objects, you select objects to add as members to the group.
- Groups associated with adapters. Each adapter manages the membership of the group. For example, the vCenter Server adapter adds groups such as datastore, host, and network, for the container objects in the vSphere inventory. To modify these groups, you must do so in the adapter.

Administrators of VCF Operations can set advanced permissions on custom groups. Users who have privileges to create groups can create custom groups of objects and have VCF Operations apply a policy to each group to collect data from the objects and report the results in dashboards and views.

When you create a custom group, and assign a policy to the group, the system uses the criteria defined in the applied policy to collect data from and analyze the objects in the group. VCF Operations reports on the status, problems, and recommendations for those objects based on the settings in the policy.

> **Note:**
> Only custom groups defined explicitly by users can be exported from or imported to VCF Operations. Users are able to export or import multiple custom groups. Once an import function has been executed, the user must check to determine if a policy or policies should be associated with the imported group. Export-import operations are available for user defined (created explicitly by user) custom groups only.

### How Policies Help VCF Operations Report On Object Groups

When you apply a policy to an object group, VCF Operations uses threshold settings, metrics, super metrics, attributes, properties, alert definitions, and symptom definitions that you activated in the policy to collect data from the objects in the group, and report the results in dashboards and views.

When you create a new object group, you have the option to apply a policy to the group.

- To associate a policy with the custom object group, select the policy in the group creation wizard.
- To not associate a specific policy with the object group, leave the policy selection blank. The custom object group will be associated with the default policy. If the default policy changes, this object group will be associated with the new default policy.

VCF Operations applies policies in priority order, as they appear on the Active Policies tab. When you establish the priority for your policies, VCF Operations applies the configured settings in the policies according to the policy rank order to analyze and report on your objects. To change the priority of a policy, you click and drag a policy row. The default policy

is always kept at the bottom of the priority list, and the remaining list of active policies starts at priority 1, which indicates the highest priority policy. When you assign an object to be a member of multiple object groups, and you assign a different policy to each object group, VCF Operations associates the highest ranking policy with that object.

## Object Group Types in VCF Operations

An object group type is an identifier that you apply to a specific group of objects in your environment to categorize them. You can add new group types, and apply them to groups of objects so that VCF Operations can collect data from the object group and display the results in the dashboards and views.

### How the Group Types Work

Use group types to categorize your objects so that the system can apply policies to them to track, and display specific status, such as alerts, workload, faults, risk, and so on.

When you create a new group type, VCF Operations adds it to the existing list of group types, and creates a new folder with the name of your group type in the Environment Custom Groups list.

When you create a new group of objects, you assign a group type to that group of objects. You add objects from the inventory trees to your custom group, then create your dashboard, add widgets to the dashboard, and configure the widgets to display the data collected from the objects in the group. You can then monitor and manage the objects.

You can apply a group type to a group of objects that you create manually, or to object groups that you cannot modify, such those added by adapters. Each adapter that you add to VCF Operations adds one or more static groups of objects to group the data received from the adapter sources.

The list of group types appears in the Content area under Group Types. The custom object groups appear in the Environment area under Custom Groups.

### Where You Create and Modify a Group Type

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then click **Custom Group and Datacenters**. Click **Group Types** next to custom groups. You can add, edit, delete, and select groups from the group types page.

### Group Type Options

You can add, edit, or delete group types. You cannot edit group types that are created by adapters.

## Groups Tab on the Environment Overview Pane

Groups are containers that can contain any number and type of objects in your environment. VCF Operations collects data from the objects in the group and displays the results in dashboards and views that you define.

### How Groups Work

Groups are installed with VCF Operations, created by an adapter, or created by a user. Based on the group criteria, you can use groups to organize your environment and monitor all objects in the group together. You can also assign policies to groups and make group membership dynamic.

For example, if you have a set of vSphere hosts and you do not want to generate alerts when the host goes into maintenance mode, you can put the vSphere hosts in a group and assign a policy that includes a maintenance schedule setting. During the maintenance period, VCF Operations ignores any metrics for those objects and does not generate any alerts. After the maintenance period ends, VCF Operations returns to monitoring the objects and generates alerts if an outage occurs.

### Where You Find Custom Groups

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Custom Groups** tile.

### Custom Group Options

Click **ADD** button to add a group. You can only edit, clone, or delete a user-created group. You cannot modify groups installed with VCF Operations or by an adapter.

You can click the **Horizontal Ellipses** to import or export the custom group. The Groups data grid displays an overview of the state of each group. You can use the All Filters option to sort the custom groups based on Name, ID, Group Type, and Description columns.

To sort the list of custom groups based on columns, click the column heading of the following columns:

- Name
- Group Type
- Health
- Description
- Members Count

**Table 1247: Group Data Grid Options**

| Option | Description |
|---|---|
| Name | Select the group name to display a summary of the group. Select to the right of the name to edit, clone, or delete the group. |
| Summary | Criticality of the health of any group. Click a group with a red, orange, or yellow criticality to get more details about potential problems with objects in the group. |
| Members Count | Displays the number of members in the selected group. |
| Policy | Displays the policy associated with the selected group. |
| Dynamic Membership | Displays whether the group is static or dynamic. The available options are true and false. |
| Defined by | Displays who has defined the attributes of the group. The available options are:<br>• System<br>• User Defined<br>• Management Pack |

## Custom Object Groups Workspace

You can create and edit custom groups of objects to have VCF Operations collect data from the objects and display the results in the dashboards and views so that you can monitor your objects and take action on them when problems occur.

### How the Custom Groups Workspace Works

When you create a new object group, you define a meaningful group name, and select the group type. To associate the custom object group with a policy for analysis, you select the policy in the group creation wizard. You can leave the policy selection blank to not associate a policy with the object group. When the policy selection is blank, the custom object group is associated with the policy that is designated as the default policy.

You select the object types, and determine whether membership in the object group is static, dynamic, or a combination of static and dynamic membership.

- To create a static object group, you add objects to the group. You do not include criteria for object membership.
- To create a dynamic object group that VCF Operations updates based on specific criteria, you select the object type and define membership criteria for the group based on metrics, relationships, and properties.

When you add objects to a custom object group, a new folder appears in the Custom Groups navigation pane on the left, and includes the member objects.

### Where You Create and Modify Object Groups

To create or modify static or dynamic object groups, or object groups that have a combination of static and dynamic membership, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click

**Administration** > **Configurations**, and then click the **Custom Groups** tile. The **Custom Groups** page displays a list of custom object groups, and the object groups for adapters added to VCF Operations.

To edit existing groups, select a group, and then click the vertical ellipsis and select **Edit**.

Custom Object Groups Workspace to Create a New Group

You can create a new object group, define custom properties, assign a group type and objects to the group. When you create the group, you can assign a policy, or leave the policy selection blank to apply the default policy. VCF Operations collects data from the objects in the group based on the settings in the policy that is associated with the group. The results appear in the dashboards and views.

## Where You Assign Custom Group Type, Policy, and Membership

To assign the group type, policy, and membership, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**, and then click the **Custom Groups** tile. Click **Add** to add a new group. In the New Group workspace, you can define the membership criteria, and select the objects to include or exclude.

To associate a policy with the custom object group, select the policy in the group creation wizard. To not associate a specific policy with the object group, leave the policy selection blank. The custom object group will be associated with the default policy. If the default policy changes, this object group will be associated with the new default policy.

**Table 1248: New Group Workspace**

| Option | Description |
|---|---|
| **Custom Group Tab** | |
| Name | Meaningful name of the object group. |
| | Meaningful description for the object group. |
| Group Type | Categorization for the object group. New custom groups appear in a dedicated folder in the Custom Groups navigation pane on the left. |
| Policy | Assigns a policy to one or more groups of objects to have VCF Operations analyze the objects according to the settings in your policy, trigger alerts when the defined thresholds are violated, and display the results in dashboards, views, and reports. You can assign a policy to the group when you create the group, or you can assign it later from the edit custom group wizard or from the policies area. |
| Keep group membership up to date | For dynamic object groups, VCF Operations can discover objects that match the criteria for the group membership according to the rules that you define, and update the group members based on the search results. |
| **Define Membership Criteria Tab** | |

| Option | Description |
| --- | --- |
| Membership Criteria | Defines the criteria for a dynamic object group and has VCF Operations keep the object membership of the group current.<br>• Object Type drop-down menu. Selects the type of objects to add to the group, such as virtual machines.<br>• Metrics, Relationship, and Properties criteria drop-down menu. Defines the criteria for VCF Operations to apply to collect data from the selected objects.<br>– Metrics. An instance of a data type, or attribute, that varies based on the object type. A metric is used as measurement criteria to collect data from objects. For example, you can select system attributes as a metric, where an attribute is a type of data that VCF Operations collects from objects.<br>– Relationship. Indicates how the object is related to other objects. For example, you can require a virtual machine object to be a child object that contains a certain word in the vSphere Hosts and Clusters navigation tree.<br>– Properties. Identifies a configuration parameter for the object. For example, you can require a virtual machine to have a memory limit that is greater than 100KB.<br>– Object Name. Specifies the name of the object. For example, you can create custom group which contains object with specific names.<br>– Tag. Specifies a tag for the object. For example, you can create membership criteria based on specific tags.<br>**Note:**<br>For the Metrics and Properties criteria drop-down menu, the metrics presented by default are a subset of available metrics. If the desired metric is not represented, use the **Select Object** button in the title bar of the data selection tree to re-filter the displayed list.<br>• You can use the filtering option to define the membership criteria for a group. The available options are:<br>– is - Displays the result of the typed text. Example - "!", displays all results equal to the symbol "!"<br>– is not - Displays the result of the typed text. Example - "1_node", displays all results not equal to "1_node"<br>– contains -Displays the result of the typed text. Example - "An", displays all results that contain "An"<br>– does not contain - Displays the result of the typed text. Example - "An", displays all results that does not contain "An"<br>– starts with - Displays the result of the typed text. Example - "!!", displays all results that starts with "!!"<br>– ends with - Displays the result of the typed text. Example - "N", displays all results that ends with "N"<br>– does not start with - Displays the result of the typed text. Example - "N", displays all results that does not start with "N"<br>– does not end with - Displays the result of the typed text. Example - "S", displays all results that does not end with "S"<br>– matches regular expression - Displays the result if it matches the regular expression. Example .*8\.\d*<br>– does not match regular expression Displays the result if it does not match the regular expression. Example .*8\.\d*<br>• Add. Includes another metric, relationship, or property for the object type.<br>• Remove. Deletes the selected object type from the membership criteria, or delete the selected metric, relationship, or property type from the criteria for the object type.<br>• Add another criteria set. Adds another object type to add to the group. For example, you might want to create a single object group to track vCenter instances and Host Systems. |
| **Objects to Include/Exclude Tab** | |

| Option | Description |
|---|---|
| Objects To Always Exclude | Determine which objects to exclude from the group every time VCF Operations collects data from the objects, regardless of the membership criteria. The objects that you include override the criteria that you define for membership. In previous versions of VCF Operations, these objects were called a denylist.<br>• **Select Objects Pane > Inventory Tab**. Displays the list of available object groups. Click on an object group to view the objects in the right pane. You can select some or all the objects in the object group and drag and drop it to the left pane for exclusion from the custom group.<br>• **Select Objects Pane > Custom Group Tab**. Displays the list of available custom groups. Click on a custom group and drag and drop it to the left pane for exclusion from the custom group.<br>• From the left pane, select the objects you want to delete and click **Remove** to delete the objects that you have added for exclusion from the custom group. |
| Objects To Always Include | Determine which objects to include in the group every time VCF Operations collects data from the objects, regardless of the membership criteria. The objects that you include override the criteria that you define for membership. In previous versions of VCF Operations, these objects were called an allowlist.<br>• **Select Objects Pane > Inventory Tab**. Displays the list of available object groups. Click on an object group to view the objects in the right pane. You can select some or all the objects in the object group and drag and drop them to the left pane for inclusion into the custom group.<br>• **Select Objects Pane > Custom Group Tab**. Displays the list of available custom groups. Click on a custom group and drag and drop it to the left pane for inclusion into the custom group.<br>• From the left pane, select the objects you want to delete and click **Remove** to delete the objects that you have added for inclusion to the custom group. |
| **Assign Custom Properties Tab** | |
| Assign Custom Properties | In VCF Operations, you can define custom properties to collect and store operational data related to different objects. The custom property can be either a string or a numeric. You can assign the newly defined custom properties to new groups or existing groups.<br>• Property Name. Select or specify a name for the custom property.<br>• Type. Select the type of custom property from the drop-down menu.<br>The custom property can either be a string or a numeric.<br>• Value. Specify a custom property value, which should be assigned to this custom property when an object is added to the group.<br>• Reset Value. Specify a custom property value, which should be assigned to this custom property when an object leaves the group.<br>• **Reset**. Resets the custom property to a non-zero value.<br>• **Remove**. Removes the custom property from the group.<br>• **Add Another Custom Property**. Adds another custom property to the group. |

- Use the **Previous** and **Next** buttons to navigate between the tabs.
- Use the **Next** button to move to the next tab.
- Use **Create** button to save and create the custom group.
- Use the **Preview** button to preview the list of objects in the group and to verify that the criteria you defined is applicable to the group of objects. If the criteria that you defined is valid, the preview displays applicable objects. If the criteria is not valid, the preview does not display any objects.

## Inventory Details and Tabs

The organization of the tabs and options in VCF Operations provides a built-in workflow that you can use when you work with objects in your environment.

The tabs, **Summary**, **Metrics**, **Alerts**, **Topology**, **Capacity**, and so on, provide progressive levels of detail about the selected object. As you work through the tabs, starting with the high level **Summary** and **Alerts** tabs, you see the general state of an object. The **Environment** tab provides you with specific data about the object.

As you monitor objects in your environment, you discover which tabs provide the information that you need when you are investigating problems.

## Inventory Page and Inventory Detailed View

You can view details of vCenter instances and VCF instances and from the **Inventory** page. You can also view a detailed list of the inventory in your VCF Operations environment where the objects are grouped logically. When you select an object from the detailed view, you see information such as summary information, metrics, alerts, capacity, and other details specific to the selected object.

### Inventory Page

To access the **Inventory** page, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**.

> **Note:**
> If you see the Inventory detailed view, click **Basic View** at the top in the **Inventory** panel.

The **Inventory** page lists all the vCenter instances that have been configured. At the top of the page, you can view environment details such as the number of VCF accounts, vCenter accounts, data centers, clusters, hosts, VMs, and datastores.

**Table 1249: Options in the Data Grid of the Inventory Page**

| Option | Description |
|---|---|
| vCenter Name | Displays the names of the vCenter instances that are configured. |
| Type | Displays all account types. |
| Data centers | Displays the number of data centers in the environment. |
| vSphere Clusters | Displays the number of vSphere clusters that have been configured. |
| Hosts | Displays the number of hosts in the environment. |
| Virtual Machines | Displays the number of VMs in the environment. |
| Datastores | Displays the number of datastores in the environment. |
| Collection State | Displays the collecting state such as Collecting, Not Collection, and so on. |

### Inventory Detailed View

The Inventory detailed view is a panel that displays logical grouping/hierarchies for the vCenter and and VCF Instances that are configured in the VCF Operations environment. You can view either a tree or list view and then select the object to view object related information.

To access the **Inventory Detailed View**, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane click **Inventory**, and then click on a vCenter instance from the data grid or click **Detailed View** from the top. You will see the **Inventory** panel with the Inventory detailed view.

**Table 1250: Options from the Inventory Detailed View**

| Option | Description |
|---|---|
| Tree view and List view | Toggle between the options to view the inventory in either a tree view or a list view. When you select a certain object your view is scoped around that object.<br>In the list view, you can see all the descendant and ancestor objects of the selected object. When you double click on any of the objects in the list view, you change the scope and the new object becomes the primary object of the view. You can select the number of ancestors or descendants for the object you want to view from the **Levels** option. |
| Hosts and Clusters | Select a host or cluster object to view the object details. |
| Storage | Select a Storage object to view the object details. |
| Networking | Select a Networking object to view the object details. |
| Custom Group and Datacenters | Select an object from Custom Groups, Custom Datacenters, or Business Applications to view the object details. |
| Integrations | Select an object from Others and All Objects to view the object details. |

**Note:**
If there are more than ten objects under a section in the Inventory detailed view, you can search for an object using the Search option. If there are more than thousand objects in a section, use the **View More** button under the last object that is displayed, to view the rest of the objects. Use the **Type to see more** button to find objects if there are more than two thousand objects.

## Evaluating Object Information Using Badge Alerts and the Summary Tab

The Summary tab that is associated with the other object tabs summarizes Heath, Risk, and Efficiency badge alerts for the selected object and displays the top alerts that lead to the current state.

Use this tab as an overview of alerts for an object, object group, or application - to evaluate the effect that alerts are having on an object and to begin troubleshooting problems. For more detail on the badge Alerts, click **Badge Alerts**, further to the right on the tool bar.

### Badge Alert Types

The Health, Risk, and Efficiency badge states are based on the impact of the generated alerts for the selected object.

- Health alerts indicate problems that affect the health of your environment.
- Risk alerts indicate problems that are not immediate threats.
- Efficiency alerts tell you where you can improve performance or reclaim resources.

### Alerts for an Object or an Object Group

For a single object, the Top alerts are the alerts generated for the object. The Top Alerts for Children are the alerts generated for any child or other descendant objects in the currently selected navigation hierarchy. For example, if you are working with a host object in the vSphere Host and Clusters navigation hierarchy, children can include virtual machines and datastores.

Object groups can include one object type, such as hosts, or multiple objects types, such as hosts, virtual machines, and datastores. When you are working with object groups, all the group member objects are children of the group container. The most critical generated alerts for the member objects appear as Top Alerts for Children.

For an object group, the only Top Alerts that might be generated are the predefined group population alerts. If the average health is above the Warning, Immediate, or Critical threshold, a group population alert considers the health of all group

members and is triggered. If a group population alert is generated, the alert affects the badge score and color. If a group population alert is not generated, then the badges are green. This behavior is because an object group is a container for other objects.

#### Summary Tab and Related Hierarchies

The alerts that appear on the **Summary** tab for an object can vary depending on the currently selected hierarchy in the Related Hierarchies in the left pane.

Depending on the selected hierarchy, you see different alerts and relationships on the **Summary** tab for an object. The current focus object name is on the center pane title bar, but the children alerts depend on the relationships that the highlighted hierarchy defined in the Related Hierarchies list in the upper left pane. For example, if you are working with a host object relative to virtual machines in the Hosts and Clusters hierarchy, then children commonly include virtual machines and datastores. But if you are working with the same host as a member of an object group, then any alerts on virtual machines that are also members of the group do not appear. The alerts do not appear because the host and the virtual machines are considered children of the group and peers among each other. In this example, the focus of the **Summary** tab is the host in the context of the group, not the Hosts and Clusters hierarchy.

#### Summary Tab Evaluation Techniques

You can evaluate the state of objects, starting with the **Summary** tab, by selecting an object or object group, click the alerts on the **Summary** tab, and resolve the problems that the alert indicates.

## Summary Tab

The Summary tab provides an overview of the state of the selected object, group, or application. Use this tab to evaluate the impact that alerts are having on the object and use the information to begin troubleshooting problems.

#### How the Summary Tab Works

Based on the object selected, the following summary tabs are displayed:

- VM Summary Tab
- Datastore Summary Tab
- Host Summary Tab
- Cluster Summary Tab
- Custom Group and Container Summary Tab

#### Where to Find the Summary Tab

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then select a group, custom data center, application, or inventory object.

#### Understanding the Summary Tab

**Table 1251: Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. It also displays the number of resources associated with the selected object. |

| Option | Description |
|---|---|
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Consumer | Gives the number of active VMs for the selected object. You can also view the usage details for the virtual machine, CPU, and Memory. |
| Provider | Gives the details of available resources for the selected object. You can view the number of hosts and capacity remaining for CPU, RAM, Storage. |
| Cluster | Displays the cluster details of the selected object. |
| Datastore | Displays the datastore details of the selected object. |

**Datastore Summary Tab**

The Datastore Summary tab provides an overview of the state of the selected datastore. For the selected object, the Datastore Summary tab displays the alerts and metrics as they affect the health, risk, or efficiency. Use this tab to evaluate the impact that alerts are having on the datastore and use the information to begin troubleshooting problems.

**Understanding the Datastore Summary Tab**

**Table 1252: Datastore Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected datastore as against the total capacity available. |
| Performance | This widget displays the summary metrics about the overall performance of the object. Click each metric to see the expanded chart. |

| Option | Description |
|---|---|
| Configuration | This widget displays the configuration details for the selected datastore object. |

### Host Summary Tab

The Host Summary tab provides an overview of the state of the selected host. For the selected object, the Host Summary tab displays the alerts and metrics as they affect the health, risk, or efficiency. Use this tab to evaluate the impact that alerts are having on the host and use the information to begin troubleshooting problems.

**Understanding the Host Summary Tab**

**Table 1253: Host Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected datastore as against the total capacity available. |
| Performance | This widget displays the summary metrics about the overall performance of the object. Click each metric to see the expanded chart. |
| Configuration | This widget displays the hardware, CPU, and Network configuration details of the host. |
| | |
| Ping Statistics | This widget displays the availability of end points that exist in your environment and other details. For more details, see Ping Account in VCF Operations. |
| .Mapped Datastore | Provides storage trends for the following datastore types -<br>• vSAN<br>• VMFS<br>• NFS<br>• VMware vSphere Virtual Volumes (vVols)<br>This tells you which datastore is running out of capacity. |

### VM Summary Tab

The VM Summary tab provides an overview of the state of the selected VM. For the selected object, the VM Summary tab displays the alerts and metrics as they affect the health, risk, or efficiency. Use this tab to evaluate the impact that alerts are having on the VM and use the information to begin troubleshooting problems.

**Understanding the VM Summary Tab**

**Table 1254: VM Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected datastore as against the total capacity available. |
| Performance | This widget displays the summary metrics about the overall performance of the object. Click each metric to see the expanded chart. |
| Configuration | This widget displays the virtual hardware, resource allocation, tools, and Network configuration details of the virtual machine. |
| Mapped Datastore | Provides storage trends for the following datastore types -<br>• vSAN<br>• VMFS<br>• NFS<br>• VMware vSphere Virtual Volumes (vVols)<br>This tells the provisioned and used storage for this VM in a particular datastore. |

### Cluster Summary Tab

The Cluster Summary tab provides an overview of the state of the selected cluster. For the selected object, the Cluster Summary tab displays the alerts and metrics as they affect the health, risk, or efficiency. Use this tab to evaluate the impact that alerts are having on the cluster and use the information to begin troubleshooting problems.

## Understanding the Cluster Summary Tab

### Table 1255: Cluster Summary Tab Options

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Virtual Machine Remaining | This widget displays the remaining virtual machines in the cluster. To see the details of the remaining virtual machines, click the Virtual Machine Remaining card. |
| Memory Tiering Nudge | Eligible clusters show a nudge that encourages you to navigate to the Capacity Optimization page and and enable memory tiering under the Resource Effeciency tab. For more information, see Using Memory Tiering for Resource Efficiency. |
| Utilization | This widget is used to find out the trends in capacity used by a selected datastore as against the total capacity available. |
| Performance | This widget displays the summary metrics about the overall performance of the object. Click each metric to see the expanded chart. |
| Configuration | This widget displays the configuration details of the cluster. |
| GPU Information | This widget is only visible if the cluster has GPU configured hosts. It displays the following GPU information:<br>• Number of GPUs: The total number of GPUs in the cluster.<br>• Compute Utilization: The compute utilization percentage of a GPU<br>• Memory Usage: The percentage of memory currently in use out of the total available memory. |
| Metadata | This widget displays the metadata details of the cluster. |
| Mapped Datastore | Provides storage trends for the following datastore types -<br>• vSAN<br>• VMFS<br>• NFS<br>• VMware vSphere Virtual Volumes (vVols)<br>This tells the provisioned and used storage for this VM in a particular datastore. |

### vCenter Server and Data Center Summary Tab

The vCenter Server and data center Summary tab provides an overview of the state of the selected data center or vCenter. For the selected object, the vCenter or data center Summary tab displays the alerts as they affect the health, risk, or efficiency. Use this tab to evaluate the impact that alerts are having on the vCenter or data center and use the information to begin troubleshooting problems.

#### Understanding the vCenter Server and Data Center Summary Tab

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Consumer | Gives the number of active VMs for the selected object. You can also view the usage details for the virtual machine, CPU, and Memory. |
| Provider | Gives the details of available resources for the selected object. You can view the number of hosts and capacity remaining for CPU, RAM, Storage. |
| vSphere Distributed Switch Name | Displays the details of the vSphere distributed switch. |
| Metadata | Displays the metadata details of the data center. |
| Cluster | Displays the cluster details of the selected object. |
| Datastore | Displays the datastore details of the selected object. |

### Resource Pool Summary Tab

The Resource Pool Summary tab provides an overview of the state of the resources in the resource pool. For the selected resource, the Resource Pool Summary tab displays the alerts and metrics as they affect the health, risk, or efficiency. Use this tab to evaluate the impact that alerts are having on the resource pool and use the information to begin troubleshooting problems.

#### Understanding the Resource Pool Summary Tab

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |

| Option | Description |
|---|---|
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Utilization | This widget is used to find out the trends in capacity used by the selected resource pool as against the total capacity available. |
| Performance | This widget displays the summary metrics about the overall performance of the object. Click each metric to see the expanded chart. |
| Resource Pool | This widget lists the resource pool name, cpu status, and memory status of the resources that are part of the corresponding resource pool. |

### Custom Group and Container Summary Tab

The Custom Group and Container Summary tab provides an overview of the state of the selected group or a container. For the selected object, the Custom Group and Container Summary tab displays the alerts and metrics as they affect the health, risk, or efficiency. Use this tab to evaluate the impact that alerts are having on the group or a container and use the information to troubleshoot the problems.

**Understanding the Custom Group and Container Summary Tab**

**Table 1256: Custom Group and Container Summary Tab Options**

| Option | Description |
|---|---|
| Recommended Actions | This widget displays the health status for the selected object and its descendants. It also displays recommendations to solve problems in an instance.<br>The badges provide a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the badge. |

### Workload Management Activated Cluster Summary Tab

The Workload Management activated cluster is a cluster with Kubernetes activated, running on vSphere (also called Supervisor cluster). It hosts a type of resource pool called Namespaces. The Workload Management Enabled Cluster Summary tab provides an overview of the state of the selected cluster.

## Understanding the Cluster Summary Tab

### Table 1257: Workload Management Enabled Cluster Summary Tab Options

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object and whether the Workload Management is activated or deactivated. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the badge. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Virtual Machine Remaining | The virtual machine remaining number is based on the average profile. The virtual machine remaining numbers are calculated when you activate one or more custom profiles from the policy. The overall virtual machine remaining is based on the most constrained profile. |
| Utilization | This widget is used to find out the trends in capacity used by a selected cluster as against the total capacity available.<br>The key utilization indicators are:<br>• CPU Capacity Usage<br>• Memory Usage<br>• Memory Balloon<br>• Disk Total IOPS<br>• Disk Total Throughput<br>• Network Usage Rate |
| Performance | This widget displays the summary metrics about the overall performance of the object. It displays the latest value and a trend line of the various key performance indicators in a color that indicates its health based on the symptom associated with the metrics. Click each metric to see the expanded chart.<br>The key performance indicators are:<br>• Max VM Memory Contention<br>• Worst Consumer Disk Latency<br>• Consumers with Memory Contention<br>• Consumers with CPU Ready<br>• Physical Network Packets Dropped<br>• Virtual Network Packets Dropped |
| Configuration | This widget displays the hardware, CPU, and Network configuration details of the host. |

| Option | Description |
|---|---|
| Namespaces | Lists the configuration status, current version and Kubernetes status of the namespaces in the cluster. |

**Namespace Summary Tab**

A namespace sets the resource boundaries where vSphere Pods and Tanzu Kubernetes clusters created by using the Tanzu Kubernetes Grid Service can run. The Namespace summary tab provides an overview of the state of the selected Namespace.

**Understanding the Namespace Summary Tab**

**Table 1258: Namespace Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status based on the alert type.<br>To see the alerts for the object, click the badge . |
| Utilization | This widget is used to find out the trends in capacity used by a selected namespace as against the total capacity available.<br>The key utilization indicators are:<br>• CPU Usage<br>• Consumed Memory |
| Performance | This widget displays the summary metrics about the overall performance of the object. It displays the latest value and a trend line of the various key performance indicators in a color that indicates its health based on the symptom associated with the metrics. Click each metric to see the expanded chart.<br>The key performance indicators are:<br>• Worst Consumer CPU Ready<br>• Worst Consumer Memory Contention<br>• Consumers with Memory Contention<br>• Consumers with CPU Ready |
| Configuration | This widget displays the following configuration details about the Namespaces:<br>• Configuration status<br>• Virtual Machines<br>• Number of Tanzu Kubernetes clusters<br>• Pods |

**vSphere Pod Summary Tab**

vSphere Pods run containers without needing to customize a Kubernetes cluster. You can deploy vSphere Pods directly on ESX hosts It hosts a type of resource pool called Namespace. The vSphere Pod Summary tab provides an overview of the state of the vSphere Pods.

## Understanding the vSphere Pod Summary Tab

### Table 1259: vSphere Pod Tab Summary Options

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining until the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected vSphere Pod as against the total capacity available.<br>The key utilization indicators are:<br>• CPU Usage<br>• Free Memory<br>• Guest Page in Rate per second<br>• Virtual Disk Total IOPS<br>• Virtual Disk Total Throughput |
| Performance | This widget displays the summary metrics about the overall performance of the object. It displays the latest value and a trend line of the various key performance indicators in a color that indicates its health based on the symptom associated with the metrics. Click each metric to see the expanded chart.<br>The key performance indicators are:<br>• CPU Queue<br>• Disk Queue<br>• CPU Ready<br>• CPU Co-stop<br>• Memory Contention<br>• Virtual Disk Total Latency<br>• Network Transmitted Packets Dropped |
| Configuration | This widget displays the hardware, CPU, and Network configuration details of the host. |

### Summary Tabs for VCF

The summary tab of VCF provides account details, overall SDDC inventory of the the organization and their the key components, aggregated metrics, alerts, and so on.

VCF Summary Tab

The VCF Summary tab provides organization details, the overall inventory of the organization including key components, alerts, and so on.

### Where To View VCF Summary

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**. In the **Inventory panel (Detailed View)**, click **Integrations** > **All Objects** > **VMware Cloud Foundation**.

**Table 1260: VCF Summary Options**

| Option | Description |
|---|---|
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Critical and Immediate alerts indicate issues that require immediate attention.<br>• Warning alerts indicate that you must look into issues shortly.<br>• Info alerts indicate that you can reclaim resources. |
| Consumer | Gives the number of active VMs for the selected object. You can also view the usage details for the virtual machine, vCPU, RAM, and Provision. |
| Provider (Usable Capacity) | Gives the details of available resources for the selected object. You can view the number of hosts and capacity remaining for vCPU, RAM, and Storage. |
| Configuration Maximums | This widget is used to find out the VCF limits and your consumption against those limits. It displays the total number of management workload domains, VI workload domains, ESX hosts, vCenter instances, and NSX clusters per domain manager. |
| Topology | Gives a graphical representation of objects related to VCF. Click each object to have an expanded view of the object details. |
| Domain Summary | Displays the domain name, type, cluster, virtual machine, datastore details, tanzu k8s cluster, namespace, and pods. |

## VCF Domain Summary Tab

The VCF Domain Summary tab provides details on the overall inventory of the domain including key components, domain health, topology, alerts, and so on.

### Where To View VCF Domain Summary Tab

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**. In the **Inventory panel (Detailed View)**, click **Integrations** > **All Objects** > **VMware Cloud Foundation**. Click the **Domain** object type and select any one of the domains in the list.

**Note:**

The VCF Domain Summary tab displays the total number of domains which includes both configured and unconfigured domains.

**Table 1261: Domain Summary Options**

| Option | Description |
|---|---|
| Object Summary | Displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | Displays a visual indicator of the alert status for the following alert types.<br>• Critical and Immediate alerts usually require immediate attention.<br>• Warning alerts indicate that you must look into any problems shortly.<br>• Info alerts indicate that you can reclaim resources. |
| Consumer | Displays the number of active VMs for the selected object. You can also view the usage details for the virtual machine, vCPU, RAM, and Provision. |
| Provider (Usable Capacity) | Displays the details of available resources for the selected object. You can view the number of hosts and capacity remaining for vCPU, RAM, Storage. |
| Topology | Displays a graphical representation of objects related to the domains. Click each object to have an expanded view of the object details. |
| Distributed Switch | Dsiplays an overview of the state of the distributed switches. It displays the distributed switch name, version, total number of hosts, the maximum number of ports, and number of used ports. |
| Cluster Summary | Displays an overview of the state of the existing clusters. It displays the cluster name, ESX host, virtual machine, capacity remaining, time remaining, and VM remaining. |
| Datastore Summary | Displays an overview of the state of the existing datastores. It displays the datastore name, capacity, virtual machine, capacity remaining, and time remaining. |

VCF World Summary Tab

The VCF World Summary tab provides details on the VCF World inventory of the organization including key components, recommended actions for the VCF organization, and the health of the object types at the world level.

**Where To View the World Summary Tab**

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**. In the **Inventory panel (Detailed View)**, click **Integrations** > **All Objects** > **VMware Cloud Foundation** > **VCF World**. Select the **VCF World** object type.

**Table 1262: World Summary Options**

| Option | Description |
|---|---|
| Recommended Actions | Displays details such as object type, number of accounts, and the recommended actions for each account.<br>This widget provides a visual indicator of the alert status for the following alert types.<br>• Critical and Immediate alerts usually require immediate attention.<br>• Warning alerts indicate that you must look into any problems shortly.<br>• Normal and Unknown alerts indicate alerts you can look at later. |
| World | Displays the health badge for the VCF World object type. You can view the average health of all group members, the compliance, efficiency, risk, workload, and the total count of critical, immediate, and normal compliance. |
| Active Alerts | Displays the visual indicator of the alert status for the following alert types. You can view the name of the object and alert description, alert type, and subtype. The time when the alert was generated, the suggested fix, and when the action was taken upon the alert. |
| Information | Displays the account information of the selected object. |

### Summary Tabs for vSAN

The summary tabs for vSAN provide the account details and an overview of the state of the selected vSAN object and it's key components like health, capacity, alerts.

vSAN Cluster Summary Tab

The vSAN Cluster tab provides an overview of the state of the selected vSAN cluster. For the selected object, the vSAN cluster tab displays the alerts, time remaining, capacity remaining, utilization, configuration, and metrics as they affect the health, risk, or efficiency. You can use this tab to evaluate the impact that alerts are having on the vSAN cluster and use that information to begin troubleshooting problems.

#### Where To View vSAN Cluster Summary Page

In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** > **Inventory Panel (Detailed View)**, and then click the **Integrations** icon. Select **All Objects**, expand **vSAN Adapter** > **vSAN Cluster**, and then select a specific **vSAN Cluster**.

**Note:**
The vSAN Cluster Summary tab displayed depends on the vSAN cluster type.

## vSAN OSA HCI Cluster Summary Tab

### Table 1263: vSAN OSA HCI Cluster Summary Tab Options

| Option | Description |
|---|---|
| Cluster Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Capacity Summary | This widget displays the physical capacity of your virtual environment to accommodate new workloads. |
| Critical Alerts | This widget displays alerts associated with the health score of the vSAN cluster. |
| vSAN Health Score | This widget displays the health score of the vSAN cluster. |
| Health Score Trend | This widget is used to find the trends in the health score of the vSAN cluster. You can view daily, weekly, and monthly health score trends. |
| What-if Free Capacity for Workload based on Chosen Policy | This widget displays the estimated capacity for a future workload. This estimate depends on the storage policy that is chosen for additional storage. |
| Utilization | This widget is used to find out the trends in capacity used by a selected vSAN cluster as against the total capacity available. |
| Contention | This widget displays the memory contention details of the vSAN cluster. |

## vSAN ESA HCI Summary Tab

### Table 1264: vSAN ESA HCI Summary Tab Options

| Option | Description |
|---|---|
| Workbench | Start the Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |

| Option | Description |
|---|---|
| Capacity Summary | This widget displays the total effective capacity, used effective capacity, free effective capacity of your virtual environment in gigabytes, when auto-RAID policy is enabled in the cluster.<br>**Note:**<br>If the auto-RAID policy is disabled, it displays the related physical capacity information.<br>It also displays the remaining capacity percentage to monitor your cluster's storage capacity to accommodate new workloads. |
| vSAN Health Score | This widget displays the health score of the vSAN cluster. |
| Health Score Trend | This widget is used to find the trends in the health score of the vSAN cluster. You can view daily, weekly, and monthly health score trends. |
| Critical Alerts | This widget displays alerts associated with the health score of the vSAN cluster. |
| What-if Free Capacity for Workload based on Chosen Policy | This widget displays the estimated capacity for a future workload. This estimate depends on the storage policy that is chosen for additional storage. |
| Utilization | This widget displays the aggregated IO performance of this vSAN cluster |
| Contention | This widget provides a snapshot of the potential bottlenecks by aggregating network reliability and disk latency/errors. |

## vSAN Compute Cluster Summary Tab

### Table 1265: vSAN Compute Cluster Summary Tab Options

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Summary | This widget displays the total effective capacity, used effective capacity, free effective capacity of your virtual environment in gigabytes. It also displays the remaining capacity percentage to monitor your cluster's storage capacity to accommodate new virtual machines. |
| Remote Datastores | Displays the remote datastores used by vSAN compute.<br>**Note:**<br>vSAN compute cluster remotely mounts the datastore of vSAN Max. |

| Option | Description |
|---|---|
| vSAN Health Score | This widget displays the health score of the vSAN cluster. |
| Health Score Trend | This widget is used to find the trends in the health score of the vSAN cluster. You can view daily, weekly, and monthly health score trends. |

## vSAN ESA Max Cluster Summary Tab

**Table 1266: vSAN Max ESA Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Client Clusters | This widget displays total number of VMs using the vSAN Max cluster for each client cluster. |
| Capacity Summary | This widget displays the total effective capacity, used effective capacity, free effective capacity of your virtual environment in gigabytes. It also displays the remaining capacity percentage to monitor your cluster's storage capacity to accommodate new virtual machines. |
| vSAN Health Score | This widget displays the health score of the vSAN cluster. |
| Health Score Trend | This widget is used to find the trends in the health score of the vSAN cluster. You can view daily, weekly, and monthly health score trends. |
| Critical Alerts | This widget displays alerts associated with the health score of the vSAN cluster. |
| Effective Free Space for Workload based on Chosen Policy | This widget displays the estimated capacity for a future workload, that is based on the selected storage policy. |
| Utilization | This widget is used to find out the trends in capacity used by a selected vSAN cluster as against the total capacity available. |
| Contention | This widget displays the memory contention details of the vSAN cluster. |

### vSAN Disk Group Summary Tab

The vSAN Disk Group Summary tab provides an overview of the state of the selected vSAN Disk Group. For the selected object, the vSAN Disk Group tab displays the alerts, time remaining, capacity remaining, utilization, configuration, and metrics as they affect the health, risk, or efficiency. You can use this tab to evaluate the impact that alerts are having on the vSAN Disk Group and use that information to begin troubleshooting problems.

**Where To View vSAN Cluster Disk Group Summary**

From the left menu, click **Inventory** > **Inventory Panel (Detailed View)** > **Integrations** > **All Objects** > **vSAN Adapter** > **vSAN Disk Group**, and then select a **Disk Group** object type.

**Table 1267: vSAN Cluster Disk Group Summary Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected vSAN cluster disk group as against the total capacity available. |
| Contention | This widget displays the memory contention details of the vSAN cluster. |
| Resync | This widget displays the throughput and latency details for the vSAN cluster disk group. |

vSAN Capacity Disk Summary Tab

The vSAN Capacity Disk tab provides an overview of the state of the selected vSAN capacity disk. For the selected object, the vSAN capacity disk tab displays the alerts, time remaining, capacity remaining, utilization, configuration, and metrics as they affect the health, risk, or efficiency. You can use this tab to evaluate the impact that alerts are having on the vSAN capacity disk and use that information to begin troubleshooting problems.

**Table 1268: vSAN Capacity Disk Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |

| Option | Description |
|---|---|
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected capacity disk as against the total capacity available. |
| Contention | This widget displays the memory contention details for the selected capacity disk. |

vSAN Cache Disk Summary Tab

The vSAN Cache Disk tab provides an overview of the state of the selected vSAN cache disk. For the selected object, the vSAN cache disk tab displays the alerts, time remaining, capacity remaining, utilization, configuration, and metrics as they affect the health, risk, or efficiency. You can use this tab to evaluate the impact that alerts are having on the vSAN cache disk and use that information to begin troubleshooting problems.

**Table 1269: vSAN Cache Disk Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected vSAN cache disk as against the total capacity available. |
| Contention | This widget displays the memory contention details for the selected cache disk. |

vSAN Cluster Fault Domain Summary Tab

The vSAN cluster fault domain summary tab provides details about CPU, CPU Cores, Memory, Disc Space and Alerts associated with the fault domain of the vSAN cluster.

**Where To View vSAN Cluster Fault Domain Summary**

On the menu, click **Inventory** > **Inventory Panel (Detailed View)** > **Integrations** > **All Objects** > **vSAN Adapter** > **vSAN and Storage Devices** > **vSAN Cluster** > **Fault Domain**.

You can also view relationship details and heat map details for the selected vSAN fault domain. The relationship section provides information about the relationship between the objects in your vSAN cluster. The heat map helps you to identify potential problems for the objects in your vSAN fault domain.

vSAN World Summary Tab

The vSAN World summary tab provides an overview of the state of all the vSAN clusters in your environment. For the selected object, the vSAN World Summary tab displays details about capacity remaining, cluster health score, vCenter, Datacenter, ESX host, vSAN Capacity, Space Efficiency, alerts, and metrics as they affect the health, risk, or efficiency of the cluster. You can use this tab to identify the vSAN ESA (Express Storage Architecture) clusters or non vSAN ESA clusters in your environment. You can evaluate the impact of alerts on vSAN clusters and use that information to begin troubleshooting problems.

**Where To View vSAN World Summary Page**

From the left menu, click **Inventory** > **Inventory Panel (Detailed View)** > **Integrations** > **All Objects** > **vSAN Adapter** > **vSAN World**, and then select a **vSAN World** object type.

**Table 1270: vSAN World Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object, you can also view the number of resources associated with the selected object. Displays the total number of vSAN clusters and the number of each vSAN cluster type. It also displays the total number of ESX hosts, virtual machines, and vSAN Datastore at the vSAN World level. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |

| Option | Description |
|---|---|
| vSAN Cluster Summary | vSAN World covers all the vSAN clusters in the environment. The cluster information is provided in a tabular format with the following columns:<br>• vSAN Cluster: Name of the vSAN cluster.<br>• Cluster Health Score: Displays the overall heath score of the cluster.<br>• vCenter: Displays the vCenter instance associated with the cluster.<br>• Datacenter: Displays the datacenter used by the cluster.<br>• vSAN Type: Displays the vSAN cluster type. For more information, see vSAN Cluster Summary Tab.<br>• ESX host: Displays the number of ESX hosts used in each cluster.<br>• vSAN Capacity: Displays the total capacity in gigabytes.<br>• Capacity Remaining: Displays the remaining capacity in each cluster in gigabytes.<br>• Space Efficiency: Displays the space efficiency feature the cluster has subscribed to during configuration.<br>• Stretched Cluster: Displays if the stretched cluster option is activated or deactivated. |

vSAN Adapter Summary Tab

The vSAN Adapter summary tab provides an overview of the state of all the vSAN adapters in your environment. For the selected object, the vSAN adapter Summary tab displays details about capacity remaining, cluster health score, vCenter, Datacenter, ESX host, vSAN Capacity, Space Efficiency, alerts, and metrics as they affect the health, risk, or efficiency of the adapter. You can evaluate the impact of alerts on vSAN adapters and use that information to begin troubleshooting problems.

**Where To View vSAN Adapter Summary Page**

From the left menu, click **Inventory** > **Inventory Panel (Detailed View)** > **Integrations** > **All Objects** > **vSAN Adapter** > **vSAN Adapter Instance**, and then select the **Adapter Instance** object type.

**Table 1271: vSAN Adapter Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object, you can also view the number of resources associated with the selected object. The vSAN ESA (Express Storage Architecture) column indicates whether the cluster is ESA activated or not. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |

| Option | Description |
|---|---|
| vSAN Cluster Summary | Each vSAN adapter instance can have one or more clusters. The cluster information is provided in a tabular format with the following columns:<br>• vSAN Cluster: Name of the vSAN cluster.<br>• Cluster Health Score: Displays the overall heath score of the cluster.<br>• Datacenter: Displays the datacenter used by the cluster.<br>• vSAN Type: Displays the vSAN cluster type. For more information, see vSAN Cluster Summary Tab.<br>• ESX host: Displays the number of ESX hosts used in each cluster.<br>• vSAN Capacity: Displays the total capacity in gigabytes.<br>• Capacity Remaining: Displays the remaining capacity in each cluster in gigabytes.<br>• Space Efficiency: Displays the space efficiency feature the cluster has subscribed to during configuration.<br>• Stretched Cluster: Displays if the stretched cluster option is activated or deactivated. |

vSAN Storage Pool Summary Tab

The vSAN Storage Pool summary tab provides an overview of the state of all the vSAN Storage pool in your environment. For the selected object, the vSAN Storage Pool Summary tab displays details about capacity remaining, vCenter, Datacenter, ESX host, vSAN Capacity, Space Efficiency, alerts, and metrics as they affect the health, risk, or efficiency of the cluster.You can evaluate the impact of alerts on the Storage Pool and use that information to begin troubleshooting problems.

**Where To View vSAN Storage Pool Summary Page**

From the left menu, click **Inventory** > **Inventory Panel (Detailed View)** > **Integrations** > **All Objects** > **vSAN Adapter** > **vSAN Storage Pool**, and then select a **Storage Pool** object type.

**Table 1272: vSAN Storage Pool Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the number of resources associated with the selected object. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Contention | This widget displays the memory contention details of the vSAN Storage Pool. |

vSAN ESA Disk Summary Tab

The vSAN ESA Disk Summary tab provides an overview of the state of the selected vSAN ESA cluster. For the selected object, the vSAN ESA cluster tab displays the alerts, time remaining, capacity remaining, utilization, configuration, and metrics as they affect the health, risk, or efficiency. You can use this tab to evaluate the impact that alerts are having on the vSAN ESA cluster and use that information to begin troubleshooting problems.

**Where To View vSAN ESA Disk Summary Page**

From the left menu, click **Inventory** > **Inventory Panel (Detailed View)** > **Integrations** > **All Objects** > **vSAN Adapter** > **vSAN ESA Disk**, and then click a **vSAN ESA Disk** object type.

**Table 1273: vSAN ESA Disk Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot | Start the Troubleshooting Workbench with the current object in context. |
| Object Summary | This widget displays the details of the selected object. The widget also displays the disk details like, size, vendor, model, queue depth, and disk type. |
| Active Alerts | This widget provides a visual indicator of the alert status for the following alert types.<br>• Health alerts that usually require immediate attention.<br>• Risk alerts indicating that you must look into any problems shortly.<br>• Efficiency alerts indicating that you can reclaim resources.<br>To see the alerts for the object, click the labels of the alert. |
| Time Remaining | This widget displays the number of days remaining till the projected resource utilization crosses the threshold for the usable capacity. |
| Capacity Remaining | This widget displays the unused capacity of your virtual environment to accommodate new virtual machines. |
| Utilization | This widget is used to find out the trends in capacity used by a selected vSAN cluster as against the total capacity available. |
| Contention | This widget displays the memory contention details of the vSAN cluster. |

**Business Application Summary Tab**

The Business Application Summary tab provides an overview of the selected Business Application. Each card on the page provides additional context such as overview, active alerts, KPIs, and object relationships between members of the Business Application.

**Understanding the Business Application Summary Tab**

**Table 1274: Business Application Summary Tab Options**

| Option | Description |
|---|---|
| Troubleshoot button | Launch the Troubleshooting Workbench with the current Business Application in context. |
| Object Summary card | Displays the details of the current Business Application.<br>• Source<br>• Application Tag<br>• Environment<br>• Business Criticality<br>• Description |
| Active Alerts card | Displays a summary of active alerts divided by **Self** and **All**, which are triggered on the Business Application and the child objects.<br>For more details about the alerts by object, see the relationship diagram, or the relationship table section. |
| Relationship view diagram | This section provides two types of relationship diagram views:<br>• Application View. This is the same relationship diagram which you can view in the Business Application page.<br>• Infrastructure View. Displays a graph of the Virtual Machines in the Business Application and their vSphere infrastructure.<br>You can switch between the horizontal view and vertical view by toggling the orientation icon on the right of the relationship view diagram.<br>Move your cursor over an object in the relationship diagram to view more details in a transient pop-up dialog box which appears. |
| Relationship view table | Displays the following details for the objects listed in the Business Application relationship diagram:<br>• Name<br>• Object Type<br>• Capacity Remaining<br>• Alerts |

## Evaluating Metric Information

The **Metrics** tab provides a relationship map and user-defined metric charts. The topological map helps you evaluate objects in the context of their place in your environment topology. The metric charts are based on the metrics for the selected object that you think helps identify the possible cause of a problem in your environment.

Although you might be investigating problems with a single object, for example, a host system, the relationship map allows you to see the host in the context of parent and child objects. It also works as a hierarchical navigation system. If you double-click an object in the map, that object becomes the focus of the map. The available metrics for the object become active in the lower-left pane.

> **Note:**
> The yellow diamond icon next to the metric indicates dynamic threshold breach, the blue diamond icon next to the metric indicates the metric value is within threshold.

You can also build your own set of metric charts. You select the objects and metrics that provide you with a detailed view of changes to different metrics for a single object, or for related objects over time.

Where available, the **Metrics** tab provides pre-defined sets of metrics to help you when looking at a specific aspect of an object. For example, if you have a problem with a host, access the most relevant information about the host by looking at the metrics displayed in the pre-defined lists. You can edit these groups of metrics, and create additional groups, by dragging and dropping metrics and properties from the All Metrics and All Properties lists.

**Where You Find the Metrics Tab**

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then select a group, custom data center, application, or inventory object.

## Create Metric Charts When You Troubleshoot a Virtual Machine Problem

You create a custom group of metric charts when you troubleshoot a problem with a virtual machine so that you can compare different metrics. The level of detail that you can create using the **Metrics** tab, can contribute significantly to your effort to find the root cause of a problem.

As an administrator investigating a performance problem with a virtual machine, you determined that you must see detailed charts about the following reported symptoms.

- Guest file system overall disk space usage reaching critical limit
- Guest partition disk space usage

The following method of evaluating problems using the **Metrics** tab is provided as an example for using VCF Operations and is not definitive. Your troubleshooting skills and your knowledge of the particulars of your environment determine which methods work for you.

1. Enter the name of the virtual machine in the **Search** text box on the menu bar.
   In this example, the virtual machine name is `sales-10-dk`.
2. Click the **Metrics** tab.
3. In the relationship topology map, click the virtual machine, **dk-new-10**.
   The metrics list, located in the left of the center pane, displays virtual machine metrics.
4. On the chart toolbar, click **Date Control** and select a time that is on or before the symptoms were triggered.
5. Add metric charts to the display area for the virtual machine.
   a) In the metric list, select **Guest Files System Stats** > **Total Guest File System Free (GB)** and double-click the metric name.
   b) To add the guest partition, for example, C:\, select **Guest Files System Stats** > **C:** > **Guest File System Free (GB)** and double-click the metric name.
   c) To add disk space for comparison, select **Disk Space** > **Capacity Remaining (%)** and double-click the metric name.
6. Compare the charts.
   You can see a decrease in the file system free space, and that the virtual machine disk space capacity remaining is decreasing at a steady rate. You determine that you must add disk space to the virtual machine. However, you do not know if the datastore can support the change to the virtual machine.
7. Add the datastore capacity chart to the charts.
   a) In the topology map, double-click the host.
      The topology map refreshes with the host as the focus object.
   b) Click the datastore.
   c) In the metric list, which is updated to display datastore metrics, select **Capacity** > **Available Space (GB)** and double-click the metric name.
8. To determine if sufficient capacity is available on the datastore to support increasing the disk space on the virtual machine, review the datastore capacity chart.

You know that you must increase the size of the virtual disk on the virtual machine.
Expand the virtual disk on the virtual machine and assign it to stressed partitions. Click **Actions**, on the object title bar, and view the virtual machine in the vSphere Web Client.

## Troubleshooting with the Metrics Tab

The **Metrics** tab provides a relationship graph and metric charts. The relationship graph helps you evaluate objects in the context of their place in your environment topology. Metric charts are based on the metrics for the active map object that you think can help you identify the cause of a problem.

### How the Metrics Tab Works

You can double-click any object in the graph and view the specific parent-child objects for the focus object. If you point to an object icon, you can see the health, risk, and efficiency details. You can also click the **Alerts** link for the number of generated alerts. Click the purple icon to view the child relationships of the object. If you double-click an object icon, the selected object becomes the focus of the map. The graph is updated for the selected object, and the metrics list shows only the metrics for the selected object.

Using the metrics list, you create charts based on metrics that you think can help you investigate problems. You customize the charts to evaluate the data in detail. To save the configured charts, you create a dashboard using the toolbar option.

Where available, the metrics list also displays pre-defined groups of metrics that contain the most relevant metrics for the selected object. You can edit these groups, and create your own customized groups of metrics by dragging and dropping metrics and properties from the All Metrics and All Properties lists.

### Where You Find the Metrics Tab

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then select a group, custom data center, application, or inventory object.
- Alternatively, in the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then use the hierarchies in the left pane to locate the objects that you want.

### Edit Metric State

The edit metric state option allows you activate, deactivate, or inherit metric state, DT state and KPI state. You can use the All Filter option to search and edit the metrics based on the following criteria.

- Name
- State
- Instanced State
- DT State
- KPI State
- Show Only Supermetrics

- Unsaved Changes

### Metrics Options

The options include the graph toolbar, the metric selector options, the metric charts toolbar, and the toolbar on each chart.

**Table 1275: Relationship Map Toolbar Options**

| Option | Description |
|---|---|
| Back to initial object | Returns the map to original object if you double-clicked on an icon to examine another object. |
| Vertical/Horizontal | Displays a vertical or horizontal view of the graph or tree view. |
| Hide Text/Show Text | Hides or displays the object names. |
| Standard View/Fit View | The **Standard View** option fixes the view to a specific zoom level. The **Fit View** option adjusts the graph or tree view to fit the screen. |

**Table 1276: Specific Functions from the Relationship Map**

| | |
|---|---|
| Hide Node | Hover your cursor over an object and click the **Hide Node** icon to hide the specific node. |
| Show Peers/Hide Peers | Hover your cursor over the selected object in the topology pane and select **ShowPeers/Hide Peers** to view or hide other objects of the same type that exist under the parent object. |
| Pagination/Next Page/Previous Page | At the bottom of the topological view you can view the page number and also move to the next/previous page. |
| Filter | At the bottom of the topological view you can use the filter option to search for objects. |
| Arrows | Use the arrows on each object to view relationships of each object. |

The chart options are used to limit the metric list.

**Table 1277: Metric Chart Selector**

| Option | Description |
|---|---|
| Show collecting metrics | Updates the list to display only the currently collected metrics for the object. |
| Show previewable super metrics | Updates the list to display super metrics for the object.<br>**Note:**<br>The super metrics only appear if the super metric is associated with the object, see Create a Super Metric topic in *VCF Operations Configuration Guide*. . |
| Actions | Click the **Actions** icon to configure metric groups. Verify that you hold the PowerUser or administrator role.<br>• **Add Group**. To add metrics or properties to the group, expand any of the metric groups, and drag one or more metrics to the group.<br>• **Remove Group(s)**. To remove one or more groups.<br>• **Rename Group**. To enter a new name for the group.<br>• **Remove Metric(s) from Group(s)**. To remove one or more metrics or properties from one or more groups, hold down the Ctrl key, and select the metrics or properties that you want to remove. |
| Search | Use a word search to limit the number of items that appear in the list. |
| Time Range | Filters the metrics to show only the ones that have received data in the selected time range. |
| Metric list | Double-click a metric to populate the chart window. To populate the chart window with a separate chart for each of the metrics in the group, double-click a metric group. |

To visualize the specific metric data over time, and compare the results for different metrics, select different combinations of options.

**Table 1278: Metric Chart Toolbar**

| Option | Description |
|---|---|
| Split Charts | Displays each metric in a separate chart. |
| Stacked Chart | Consolidates all charts into one chart. This chart is useful for seeing how the total or sum of the metric values vary over time. To view the stacked chart, ensure that the split chart option is turned off. |
| Y Axis | Shows or hides the Y-axis scale. |
| Metric Chart | Shows or hides the line that connects the data points on the chart. |
| Trend Line | Shows or hides the line and data points that represents the metric trend. The trend line filters out metric noise along the timeline by plotting each data point relative to the average of its adjoining data points. |
| Dynamic Thresholds | Shows or hides the calculated dynamic threshold values for a 24-hour period. |
| Show Entire Period Dynamic Thresholds | Shows or hides dynamic thresholds for the entire time period of the graph. |
| Anomalies | Shows or hides anomalies. Time periods when the metric violates a threshold are shaded. Anomalies are generated when a metric crosses a dynamic or static threshold, either above or below. |
| Show Data Point Tips | Shows or hides the data point tooltips when you hover the mouse over a data point in the chart. |
| Zoom All Charts | Resizes all the charts that are open in the chart pane based on the area captured when you use the range selector.<br>You can switch between this option and **Zoom the View**. |
| Zoom the View | Resizes the current chart when you use the range selector. |
| Pan | When you are in zoom mode, allows you to drag the enlarged section of the chart so that you can view higher or lower, earlier or later values for the metric. |
| Show Data Values | Activates the data point tooltips if you switched to a zoom or pan option. **Show Data Point Tips** must be activated. |
| Refresh Charts | Reloads the charts with current data. |
| Date Controls | Opens the date selector.<br>Use the date selector to limit the data that appears in each chart to the time period you are examining. |
| Generate Dashboard | Saves the current charts as a dashboard. |
| Remove All | Removes all the charts from the chart pane, allowing to you begin constructing a new set of charts. |

Manage individual charts with the toolbar options.

**Table 1279: Individual Metric Charts Toolbar**

| Option | Description |
|---|---|
| Navigation | If an adapter includes the ability to link to another application for information about the object, click the button to access a link to the application. |
| Correlation | Runs metric correlation using the following options:<br>**Self-Metrics**: Runs metric correlation on all metrics for the selected object, to find metrics of similar, or opposite behavioral change for the same time period. The instanced metrics are not assessed in the self-metrics correlation method.<br>**Peers**: Runs metric correlation on the same metrics for all peer objects, to find the same metrics with behavioral changes within peer objects. Peer objects are the direct child objects of the parent for the selected objects. The child objects have the same object type.<br>**Note:**<br>The correlation results only appears if there are at least 11 data points and the time range is within the three months period to run the metric correlation.<br>**Scope**: Runs metric correlation on all metrics for the selected object with the selected scope, to find metrics of similar, or opposite behavioral change for the same time period. The instanced metrics are not assessed in the scope correlation method.<br>After you run the correlation, the results are displayed in the **Corr elation** window. By default, only the first 10 results for correlated metrics are displayed. To view the full list, click **Show More**.<br>You can zoom in to view the correlated metrics and also pin them so that they appear in the preview section of the **All Metrics** tab.<br>**Note:**<br>During the correlation process, some metrics are left out. For example, the badge and VCF Operations generated metrics. By default, the instanced metrics are omitted, except those in the **Aggregate of all instances** group. |
| Save a Snapshot | Creates a PNG file of the current chart. The image is the size that appears on your screen.<br>You can retrieve the file in your browser's download folder. |
| Save a Full Screen Snapshot | Downloads the current graph image as a full-page PNG file, which you can display or save.<br>You can retrieve the file in your browser's download folder. |
| Create an Alert Definition | Allows you to create an alert for an object type or metric in a quick and easier way. For details, see Create a Simple Alert Definition section in *VCF Operations Configuration Guide.* . |
| Download comma-separated data | Creates a CSV file that includes the data in the current chart.<br>You can retrieve the file in your browser's download folder. |

| Option | Description |
|---|---|
| Scales | You can choose a scale for a stacked chart.<br>• Select **Linear** to view a chart in which the Y-axis scale increases in a linear manner. For example, the Y-axis can have ranges from 0 to 100, 100 to 200, 200 to 300, and so on.<br>• Select **Logarithmic** to view a chart in which the Y-axis scale increases in a logarithmic manner. For example, the Y axis can have ranges from 10 to 20, 20 to 300, 300 to 4000, and so on. This scale gives a better visibility of minimum and maximum values in the chart when you have a large range of metric values.<br>**Note:**<br>If you select a logarithmic scale, the chart does not display data points for metric values less than or equal to 0, which leads to gaps in the graph.<br>• Select **Combined** to view overlapping graphs for the metrics. The chart uses individual scales for each graph instead of using a relative scale, and displays a combined view of the graphs.<br>• Select **Combined by Unit** to view a chart that groups the graphs for similar metric units together. The chart uses a common scale for the combined graphs. |
| Move Down | Moves the chart down one position. |
| Move Up | Moves the chart up one position. |
| Close | Deletes the chart. |
| Vertical resize | Resizes the height of a graph in the chart. |
| **Remove** icon next to each metric name in a stacked chart | Removes the graph for the metric from the chart. |

## Investigating Object Alerts

The **Alerts** tab provides a list of generated alerts for the currently selected object. When you are working with objects, reviewing and responding to generated alerts on the **Alert** tab helps you manage problems in your environment.

The alerts notify you when a problem occurs in your environment based on configured alert definitions. Object alerts are useful to you as an investigative tool in two ways. They can provide you with early notification about problems in your environment before a user calls you to report a problem. As well, object alerts can provide information about the object that you can use when troubleshooting general or reported problems.

As you review the **Alerts** tab, you can add ancestors and descendants to the list to broaden your view of the alerts. You can see if alerts on the current object affect other objects. Conversely, you can examine how problems reflected in alerts on other objects affect the current object.

Depending on the practices and workflows of your infrastructure operations team, you can use the object **Alerts** tab to manage generated alerts on individual objects.

- Take ownership of alerts so that your team knows that you are working to resolve the problem.
- Suspend an alert so that is temporarily excluded from affecting the Health, Risk, or Efficiency state of the object while you investigate the problem.
- Cancel alerts that you know are a result of a deliberate action. For example, a network card is removed from a host for replacement. Also cancel alerts that are known issues that you cannot resolve currently because of resource constraints. Canceling an alert that is generated because of only message event or metric event symptoms cancels the alert permanently. If the underlying metric or property condition remains true, canceling an alert that is generated because of metric, super metric, or property symptoms can result in the alert being regenerated . It is only effective to cancel alerts generated because of message event or metric event symptoms.

Investigating and resolving alerts helps you provide the best possible environment to your customers.

## Alerts Tab

The Alerts tab is a list of all the alerts generated for the selected object, group, or application. Use the alerts list to evaluate the number of generated alerts for the object so that you can begin resolving them.

### How the Alerts Tab Works

All the active alerts for the selected object appear in the list. By default, the system groups the alerts by Definition. You can select multiple rows in the list using Shift+click, Control+click. Modify the filter if you want to see inactive alerts.

Manage the alerts in the list using the toolbar options. Click the **alert name** to see the alert details for the affected object. The alert details appear on the right, including the symptoms triggered with the alert. The system offers recommendations for addressing the alert and links to additional information. A **Run Action** button might appear in the details. Point to the button to learn what recommendation is performed if you click the button. To return to the list view, click the **X** at the top right of the alert details.

To see the object details, click the **Summary** Tab.

### Where You Find the Alerts Tab

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**, and then select a group, custom data center, application, or inventory object. Click the **Alerts** tab.

### Alerts Display Options

The alert options include toolbar and data grid options. Use the toolbar options to sort the alert list and to cancel, suspend, or manage ownership. Additional toolbar options enable you to review parent and child alerts related to the alert you are reviewing. Use the data grid to view the alerts and alert details.

**Table 1280: Actions Menu**

| Option | Description |
|---|---|
| Actions menu | Select an alert from the list to turn on the Actions menu, then select an option from the menu. |
| Menu Options: | |
| Cancel Alert | Cancels the selected alerts. If you configure the alert list to display only active alerts, the canceled alert is removed from the list.<br>You cancel alerts when you do not need to address them. Canceling the alert does not cancel the underlying condition that generated the alert. Canceling alerts is effective if the alert is generated by triggered fault and event symptoms because these symptoms are triggered again only when subsequent faults or events occur on the monitored objects. If the alert is generated based on metric or property symptoms, the alert is canceled only until the next collection and analysis cycle. If the violating values are still present, the alert is generated again. |
| Delete Canceled Alerts | Delete canceled (inactive) alerts by making a group selection or by individually selecting alerts. You cannot delete active alerts. |
| Suspend | Suspend an alert for a specified number of minutes.<br>You suspend alerts when you are investigating an alert and do not want the alert to affect the health, risk, or efficiency of the object while you are working. If the problem persists after the elapsed time, the alert is reactivated and it will again affect the health, risk, or efficiency of the object.<br>The user who suspends the alert becomes the assigned owner. |
| Assign to | Assign the alert to a user. You can search for a specific username and click **Save** to assign the alert to the selected user. |

| Option | Description |
|---|---|
| Take Ownership | As the current user, you make yourself the owner of the alert. You can only take ownership of an alert, you cannot assign ownership. |
| Release Ownership | Alert is released from all ownership. |
| Go to Alert Definition | Switches to the Alert Definitions page, with the definition for the previously selected alert displayed. |
| Deactivate | Offers two options for disabling the alert:<br>Deactivate the alert in all policies: this deactivates the alert for all objects for all the policies.<br>Deactivate Alert in Selected Policies: this deactivates the alert for objects having the selected policy. This method works only for objects with alerts. |
| Open an external application | Actions you can run on the selected object.<br>For example, Open Virtual Machine in vSphere Client. |

**Table 1281: Include Menu**

| Options | Description |
|---|---|
| Self | The selected object. |
| Parents <options> | Displays the alerts for the ancestors of the selected object. Parents in this instance include the parents, grandparents, and so on, of the object. For example, the parents of a host are a folder, storage pod, cluster, and data center instance. |
| Children <options> | Displays the alerts for the descendants of the selected object. Children in this instance include the children and grandchildren of the object. For example, the descendants of a host are datastores, resources pools, and virtual machines. |
| Peer | Shows or hides alerts for objects with the same kind of the impacted object which also share the same parent. |

**Table 1282: Group By Options**

| Option | Description |
|---|---|
| None | Alerts are not sorted into specific groupings. |
| Time | Group alerts by time triggered. |
| Criticality | Group alerts by criticality. Values are, from the least critical: Info/ Warning/Immediate/Critical. See also Criticality in the "All Alerts Data Grid Options" table, below. |
| Definition | Group alerts by definition, that is, group like alerts together. Selected by default. |
| Object Type | Group alerts by the type of object that triggered the alert. For example, group alerts on hosts together. |
| Scope | Group alerts by scope. You can search for alerts within the selected scope. |

**Table 1283: Quick Filters**

| | |
|---|---|
| Filtering options | The advanced search and filter lets you search for a symptom by:<br>• Alert ID<br>• Alert<br>• Owner<br>• Impact<br>• Alert Type<br>• Alert Subtype<br>• Status<br>• Criticality<br>• Triggered On<br>• Control State<br>• Object Type<br>• Created On<br>• Updated On<br>• Canceled On<br>• Action |

**Table 1284: Alerts Data Grid**

| Option | Description |
|---|---|
| Criticality | Criticality is the level of importance of the alert in your environment. The alert criticality appears in a tooltip when you hover the mouse over the criticality icon.<br>The level is based on the level assigned when the alert definition was created, or on the highest symptom criticality, if the assigned level was **Symptom Based**.<br>The possible values include:<br>• Critical<br>• Immediate<br>• Warning<br>• Information |
| Alert | Name of the alert definition that generated the alert.<br>Click the alert name to view the alert details tabs where you can begin troubleshooting the alert. |
| Created On | Date and time when the alert was generated. |
| Status | Current state of the alert.<br>Possible values include Active or Canceled. |
| Alert Type | Describes the type of alert that triggered on the selected object, and helps you categorize the alerts so that you can assign certain types of alerts to specific system administrators. For example, Application, Virtualization/Hypervisor, Hardware, Storage, Network, Administrative, and Findings. |
| Alert Subtype | Describes additional information about the type of alert that triggered on the selected object, and helps you categorize the alerts to a more detailed level than Alert Type, so that you can assign certain types of alerts to specific system administrators. For example, Availability, Performance, Capacity, Compliance, and Configuration. |
| Importance | Displays the priority of the alert. The importance level of the alert is determined using a smart ranking algorithm. |

### Alert Details Tab

| Section | Description |
|---|---|
| Recommendations | View recommendations for the alert. Click **<** or **>** to cycle through the recommendations. To resolve the alert, click the **Run Action** button if it appears. |
| Other Recommendations | Collapse the section to view additional recommendations. See the links in the **Need More Information?** section to view additional metrics, events, or other details that appear as a link. |
| Alert Basis | |
| Active Only | This option is activated by default. When activated, all active symptoms/conditions that were met for the alert are displayed. When deactivated, all the symptoms/conditions of an alert are displayed. |
| Symptoms | View the symptoms that triggered the alert. Collapse each symptom to view additional information. |
| Conditions | View the conditions that triggered the alert. Collapse each condition to view additional information. |
| Notes | Enter your notes about the alert and click **Submit** to save. |
| Close | Click the X icon to close the alert details tab. |

### Related Alerts Tab

The **Related Scope** displayed on the right, shows the objects that are one level above and one level below the object on which the alert was triggered. This topology is fixed. You cannot change the scope in the **Related Alerts** tab.

On the right, you can see the following:

- If the same alert was triggered on the object in the past 30 days. This helps you understand if this is a recurring problem or something new.
- If the same alert was triggered on other peers in the same environment, in the past 30 days. This helps you do a quick peer analysis to understand if others are impacted with the same problem.
- All the alerts triggered in the current topology. This helps you investigate if there are other alerts upstream or downstream in the environment which are impacting the health of the object.

### Potential Evidence Tab

See the **Potential Evidence** tab for potential evidences around the problem, and to arrive at the root cause. This tab displays events, property changes, and anomalous metrics potentially relevant to the alert. The time range and the scope are fixed. To modify the scope or the time range and investigate further, click **Launch Workbench**. This runs the troubleshooting workbench.

The time range that is displayed in the potential evidence tab is two hours and thirty minutes before the alert was triggered. VCF Operations looks for potential evidences in this time range.

## Symptoms Display

The symptoms display includes all the symptoms triggered for the current object. Use the symptom list to identify problems with an object so that you can resolve alerts generated for the object.

### How the Symptoms Work

The list is the active triggered symptoms for an object, either as part of a generated alert or as a triggered symptom that is not included in an alert. This complete symptom list is useful for identifying problems that occur on an object but are not currently included in your alert definitions.

Click a symptom in the list to display the symptom details. An arrow in each column heading enables you to order the list in ascending or descending order. You can select multiple rows in the list using Shift+click, Control+click.

**Where You Find the Symptoms Display**

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then select a group, custom data center, application, or inventory object. Click the **object** to display the object's **Summary** tab. Click the **Symptoms** subtab in the **Alerts** tab.
- In the menu, select **Search** and locate the object of interest. Click the **object** to display the object's **Summary** tab. Click the **Symptoms** subtab in the **Alerts** tab.

**Table 1285: Symptoms Data Grid**

| Option | Description |
|---|---|
| Criticality | Criticality is the level of importance of a symptom in your environment.<br>The level is based on the same level assigned when the symptom was created. The possible values include:<br>• Critical<br>• Immediate<br>• Warning<br>• Information |
| Symptom | Name of the triggered symptom. |
| Status | Current state of the symptom.<br>Possible values are Active or Inactive. |
| Created On | Date and time when the alert was generated. |
| Canceled On | Date and time when the symptom was canceled. |
| Information | Information about the triggering condition for the symptom, including the trend and current value.<br>The sparkline displays a range of data that includes six hours before the symptom update time and one hour after the update time. |

**Table 1286: Actions Menu**

| Option | Description |
|---|---|
| Actions menu | Select the **Go To Symptom Definition** option to open the **Symptom Definitions** page in the **Configure** > **Alerts** path. |

**Table 1287: Include**

| Option | Description |
|---|---|
| Self | Shows or hides symptoms for the current object. |
| Peer | Shows or hides symptoms for objects like the impacted object. |
| Parents <options> | Shows or hides symptoms for the parent, grandparent, and so on, objects of the current object. |
| Children <options> | Shows or hides the symptoms for the descendants of the impacted object. |

**Table 1288: Filters**

| | |
|---|---|
| Filtering options | The advanced search and filter lets you search for a symptom by:<br>• Symptom<br>• Status<br>• Criticality<br>• Triggered On<br>• Created On<br>• Canceled On |

**Table 1289: Group By Options**

| Option | Description |
|---|---|
| None | Symptoms are not sorted into specific groupings. |
| Time | Group Symptoms by time triggered. |
| Criticality | Group Symptoms by criticality. Values are, from the least critical: Info/Warning/Immediate/Critical. |
| Definition | Group Symptoms by definition, that is, group like Symptoms together. The default. |
| Object Type | Group Symptoms by the type of object that triggered the alert. For example, group Symptoms on hosts together. |
| Scope | Group Symptoms by scope. You can search for Symptoms within the selected scope. |

## Events Display

An event is any change to an object defined by a change in the metrics for that object. You can compare changes to an object with symptoms and other data to identify a possible cause for a generated alert.

### How the Events Display Works

The Events tab is a list of all the events generated for the selected object, group, or application based on messages send by either external sources or by internal self troubleshooting system.

The following vCenter activities are some of the activities that generate VCF Operations events:

- Powering a virtual machine on or off
- Creating a virtual machine
- Installing VMware Tools on the guest OS of a virtual machine
- Adding a newly configured ESX system to a vCenter system

Depending on alert definitions, these events might generate alerts.

You might monitor the same virtual machines with other applications that provide information to VCF Operations, with the adapters for those applications configured to provide change events. In this instance, the **Events** tab includes certain change events that occur on the monitored objects. These change events might provide further insight into the cause of problems that you are investigating.

### Where You Find the Events Display

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then select a group, custom data center, application, or inventory object. Click the **object** to display the object's **Summary** tab. Click the **Events** subtab in the **Alerts** tab.

- In the VCF Operations navigation bar at the top, select **Search** and locate the object of interest. Click the **object** to display the object's **Summary** tab. Click the **Events** subtab in the **Alerts** tab.

**Table 1290: Include**

| Option | Description |
|---|---|
| Self | Shows or hides events for the current object. |
| Peer | Shows or hides events for objects like the impacted object. |
| Parents <options> | Shows or hides events for the parent, grandparent, and so on, objects of the current object. |
| Children <options> | Shows or hides the events for the descendants of the impacted object. |

**Table 1291: Events Data Grid**

| Option | Description |
|---|---|
| Criticality | Criticality is the level of importance of the event in your environment. The event criticality appears in a tooltip when you hover the mouse over the criticality icon.<br>The level is based on the level assigned when the event definition was created, or on the highest symptom criticality, if the assigned level was **Symptom Based**.<br>The possible values include:<br>• Critical<br>• Immediate<br>• Warning<br>• Information |
| Object Name | Name of the event definition that generated the event. Click the event name to view the event details tabs where you can begin troubleshooting the event. |
| Event Type | Describes the type of event that triggered on the selected object, and helps you categorize the event so that you can assign certain types of events to specific system administrators. For example, Application, Virtualization/Hypervisor, Hardware, Storage, Network, Administrative, and Findings. |
| Information | Describes additional information about the type of event that triggered on the selected object, and helps you categorize the events to a more detailed level. |
| Created On | Date and time when the event was generated. |
| Cancelled On | Date and time when the event was cancelled. |

**Table 1292: Filters**

| | |
|---|---|
| Filtering options | The advanced search and filter lets you search for a event by:<br>• Symptom<br>• Status<br>• Criticality<br>• Triggered On<br>• Created On<br>• Canceled On |

**Table 1293: Group By Options**

| Option | Description |
|---|---|
| None | Events are not sorted into specific groupings. |
| Time | Group events by time triggered. |
| Criticality | Group events by criticality. Values are, from the least critical: Info/ Warning/Immediate/Critical. |
| Definition | Group events by definition, that is, group like events together. |
| Object Type | Group events by the type of object that triggered the alert. For example, group events on hosts together. |
| Scope | Group events by scope. You can search for events within the selected scope. |

## Timeline Display

The generated alerts, triggered symptoms, and change events for the current object over time appear on the **Timeline** display. You use the timeline to identify common trends over time that are contributing to the status of objects in your environment.

### How the Timeline Display Works

The Timeline works by combining the data for alerts, symptoms and events and displaying it in a unified view. By default only active items are shown, however you can customize the data for each independently tab by using the filters to the top right and from the **INCLUDE** menu, which allows you to use parent, child and peer options to examine the object in a broader environmental context, as it is not always effective to investigate a problem on an individual object by looking only at the object. This context often reveals unexpected influences or consequences for the problem.

The timeline is a tool that provides you a graphical view of patterns. If the system triggers a symptom and then cancels it at various intervals over time, you can compare the event to other changes to the object or to the related objects. These changes might be the root cause of the problem.

The view is limited to 700 alerts, symptoms, and events accordingly. If your timeline includes more than this number, you can use the filters in each tab to remove data from the timeline until it contains data that you find useful for your investigation.

### Where You Find the Events Timeline

- In the VCF Operations navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory** and then select a group, custom data center, application, or inventory object. Click the **object** to display the object's **Summary** tab. Click the **SHOW TIMELINE** button in the **Alerts** tab.
- In the VCF Operations navigation bar at the top, select **Search** and locate the object of interest. Click the **Alert** tab, then to display the object's **Summary** subtab. Click the **SHOW TIMELINE** button in the **Alerts** tab

**Table 1294: Filter By**

| Option | Description |
|---|---|
| Filter By | Filter By Menu uses the data from Timeline view to display controls for further filtering the data.<br>It can contain alert types and subtypes, event types and criticality levels. Additionally it its possible to hide entire sections like Alerts, Symptoms or Events. |

**Table 1295: Time Range**

| Option | Description |
|---|---|
| Range | Select a time range. The default is **Last 24 hours.** |
| From - To | Select a time range by inputting a combination of date and time for the **From** and **To** fields. |

## Topology Tab

The Topology tab allows you to view the relationship of the objects in a topological view.

**Table 1296: Topology View Toolbar Options**

| Option | Description |
|---|---|
| Back to initial object | Returns the map to original object if you double-clicked on an icon to examine another object. |
| View Tree | Displays a tree view of the relationships. |
| View Graph | Displays a graph view of the relationships. |
| Applications | Displays relationships that are of the type 'application'. |
| View Additional Links | Displays additional links for the applications. |
| Vertical/Horizontal | Displays a vertical or horizontal view of the graph or tree view. |
| Hide Text/Show Text | Hides or displays the object names. |
| Standard View/Fit View | **Standard View**: Fixes the view to a specific zoom level.<br>**Fit View**: Adjusts the graph or tree view to fit the screen. |
| Settings | • **Parent Depth**: Displays up to five levels of parent objects for the selected object depending on your selection.<br>• **Child Depth**: Displays up to five levels of child objects for the selected objects, depending on your selection.<br>• **Page Size**: Sets the number of objects per page. |

**Table 1297: Specific Functions from the Topology Grid View**

| | |
|---|---|
| Hide Node | Hover your cursor over an object and click the **Hide Node** icon to hide the specific node. |
| Show Peers/Hide Peers | Hover your cursor over the selected object in the topology pane and select **ShowPeers/Hide Peers** to view or hide other objects of the same type that exist under the parent object. |
| Pagination/Next Page/Previous Page | At the bottom of the topological view you can view the page number and also move to the next/previous page. |
| Filter | At the bottom of the topological view you can use the filter option to search for objects. |
| Arrows | Use the arrows on each object to view relationships of each object. |

## Environment Tab

VCF Operations discovers the descendants of the selected object and lists them. The Environment tab provides you with specific data about the object.

## How the Environment Tab Works

Descendant objects of the object you selected appear in the datagrid of the **Environment** tab. To find a particular object, you can sort a column in the grid or search for a word in the filter, or use the filter options.

## Where You Find the Environment Tab

From the left menu, click **Inventory** and then click a vCenter instance from the datagrid. From the **Inventory** panel, select an object and then click the **Environment** tab.

Use the toolbar options to manage objects.

- Filter options limit the list to objects matching the filter. Filter options include All, ID, Internal ID, Name, Description, Adapter Type, Object Type, and Identifiers.
- Select the object to manage from the list.

### Table 1298: Toolbar Options

| Option | Description |
|---|---|
| Actions | Perform an action on the selected object. Available actions depend on the object type. For example, Power on VM applies to the selected virtual machine. |
| Open in external application | If an adapter includes the ability to link to another application for information about the object, click the button to access a link to the application. For example, Open Virtual Machine in a vSphere Client or Search for VM logs in Log management. |
| Edit Object | Edit the selected object. For example, add or change the maintenance schedule for a virtual machine. If multiple objects of the same type are selected, common identifiers for the object type are editable. For example, change the VM entity name of multiple datastores with a single edit. |
| Add Object | VCF Operations discovers objects for most adapters. For adapters that do not support autodiscovery for all objects, the objects are manually added. See Manage Objects Workspace. |
| Discover Objects | Perform an IP scan to discover objects associated with a particular adapter. See Discover Objects Workspace. |
| Delete object | Remove the object from the list. |
| Start maintenance | Take the object offline for maintenance. See Manage Maintenance Schedules for Your Object Workspace. |
| End maintenance | Terminate the maintenance period and put the selected object back online. |
| Clear Selections | Clear all object selections. |
| Select All | Select all objects displayed. |
| Add/Edit Custom Property | Define or add custom properties. |
| Go to Details | Display the **Summary** tab of the selected object. |
| Page Size | The number of objects to list per page. |

### Table 1299: Datagrid Options

| Option | Description |
|---|---|
| Name | Displays the name of the object. |
| Adapter Type | Displays the name of the adapter. |

| Option | Description |
|---|---|
| Object Type | Displays the type of object. |
| Policy | Displays the policy associated with the object. |
| Collection State | Displays the collection state of an adapter instance for each object. |
| Collection Status | Displays the collection status of an adapter instance of each object. |

# Configuring Automation Jobs

You can automate jobs to perform certain actions as per a schedule. You can create and manage automation jobs from the Automation Central page. Scheduling of jobs allows you to perform actions without manual supervision. For example, you can automate jobs to run during a maintenance window, which could be outside of working hours.

## Automation Central

Automation Central is where you can create jobs to automate optimization actions which reclaim or rightsize VMs. You can also schedule additional actions such as powering on, powering off, and rebooting VMs and instances. Once you set up recurring jobs, you can track and obtain reports on them. You can customize jobs so that they only run based certain on parameters. For example, if you choose to delete a snapshot as an action, you can specify how old the snapshot must be before it is deleted. You can also schedule jobs from the Reclaim and Rightsizing pages, where you configure the job in the context of a recommendation provided by VCF Operations.

### Actions that you can Automate

You can automate the following actions using Automation Central:

| | |
|---|---|
| **Reclaim** | • Delete old snapshots. You can include idle and powered off VMs for reclamation.<br>• Delete idle VMs<br>• Poweroff Idle VMs<br>• Delete powered off VMs |
| **Rightsize** | • Downsize oversized VMs. You can include idle VMs when resizing.<br>• Scale-up undersized VMs. |
| **Other** | Schedule additional actions such as powering on, powering off, and rebooting VMs and instances. The additional actions are based on the public cloud (GCP, AWS, Microsoft Azure) or vCenter adapter. |

### Where you find Automation Central

After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Automation Central**.

### How Automation Central Works

In the Automation Central page you see a list of upcoming jobs and a calendar under the **Schedule** tab. The calendar displays all the jobs that are scheduled for the current month. You can move between months to see more scheduled jobs.

| | |
|---|---|
| **View the Summary of Scheduled Jobs** | When you click on a date in the calendar, you see a summary of the job. The summary displays the frequency of the job, the type of job, and if the job is activated or deactivated. You can click **Preview** to see more details about the job, or click **Deactivate All Recurrences** to deactivate the job. To edit the job, click the **Edit** link. |
| **View a Report of Jobs** | View reclamation and rightsizing reports. The reclamation report displays graphical and numerical data on the total cost saving, CPUs reclaimed, memory reclaimed and storage reclaimed for different time periods. The rightsizing reports displays graphical and numerical data on the CPUs downsized, memory downsized, CPU oversized, and memory upsized for different time periods. |

| | |
|---|---|
| **View Job History** | You can also view the history of configured jobs which have run. Click the **History** tab above the calendar to see the job name, and job details in a tabular format. Use the search to search for a Job or VM. Click the drop-down in the search box to perform an advanced search.<br><br>The job history page only displays the status of jobs. For detailed information about the task, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Control Panel** > **Recent Tasks**. Failed recurring jobs are triggered during the next run.<br><br>If VM Power Off is not allowed, the action fails and is indicate as such in the logs. |
| **View Configured Jobs** | The **Jobs** tab is where you see a list of configured jobs. For each job, clicking the ellipses icon brings up a menu from where you can edit, delete, clone or deactivate the job. If a job that you created is not visible in the list, search for it by entering the name in the search box. Alternatively, you can check by the job status by clicking the drop-down in the search box for advanced search options. |

### Prerequisites to Run Actions

Actions are run through VMware tools. vCenter privileges required to run each actions is documented in topic, Privileges Required for Configuring a vCenter Account. Automation Central calls vCenter APIs with the credentials supplied to the vCenter adapter in VCF Operations.

Automation Central is available for users who have the advanced license and above. You must have the necessary permission to schedule and manage jobs in the **Automation Central** page. An administrator can manage these permissions in the **Roles** tab available when you click **Operate** in the top navigation bar, and in the left navigation pane, click **Administration** > **Control Panel** > **Access Control**. Make sure that the **Manage Job Schedules** permission is selected in the **Assign Permissions** section, under Operations. This is available when you expand the **Automation Central** category.

To schedule a job of a specific type, you must have permission to run the corresponding action defined under **Administration** > **Global Inventory** > **Actions** in the **Roles** tab when you navigate to **Administration** > **Control Panel** > **Access Control**.

**Operational Actions** must be enabled in the vCenter cloud adapter instance to run actions from Automation Central.

To use alternate user credentials for actions, see the topic, Configuring a vCenter Account in VCF Operations.

### Troubleshooting Automation Jobs

To see the logs for scheduled jobs, click **Operate** in the top navigation bar, and in the left navigation pane, click **Administration** > **Control Panel** > **Support Logs** > **Others** and look for the following logs:

- actionScheduler-.log
- actions-data-.log

Or, click **Operate** in the top navigation bar, and in the left navigation pane, click **Administration** > **Control Panel** > **Support Logs** > **Analytics** and search for action execution in analytics-.log.

## Create Job from Automation Central

Create a job to schedule an action to be performed automatically. You can select the type of action you want to perform, and then select the scope of the action. You can filter the scope based on attributes and metrics. Every action has a configuration option, which enables you to control the execution of the job based on conditions.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Automation Central**. In the Automation Central page, click **Add Job**.

   The **Create New Job** page opens. This page displays the following cards:

   - Reclaim
   - Rightsize
   - Billing . This card is available when you when you have VMware Cloud Director configured in VCF Operations. For more information, see the topic, Scheduling Bill Generation Using Automation Central.
   - Actions

2. Click on a card based on the type of job you want to create.
3. In the first step of the wizard, specify the following properties to create the action:

| Property | Description |
|---|---|
| **Name** | Specify a name for the job. This is displayed in the calendar. |
| **Description** | Provide a description for the job. |
| **Action Configuration** | Select this option for scheduling VM optimization actions. The choices are:<br><br>**Reclaim**:<br><br>1. Delete old snapshots. When you select this option, you must specify at least one of the following:<br>– The snapshot age in days.<br>– The snapshot size in MB using the operators from the drop-down list.<br>– The snapshot name, using one of the operators from the drop-down list.<br>– Select the checkboxes to reclaim idle and powered off VMs.<br><br>**Note:**<br>The criteria for snapshot deletion is a combination of all the options you choose.<br>2. Delete idle VMs. When you select this option, you must specify the idle time duration in days.<br>3. Power off idle VMs. When you select this option, you must specify the idle time duration in days.<br>4. Delete powered off VMs. When you select this option, you must specify the power off duration in days.<br><br>**Note:**<br>The time definition for powered off VMs, idle VMs, and snapshots is configured **Capacity** > **Reclaim** > page. Click the **Settings** link on the page to edit or view the reclamation settings. Ensure that you have reviewed the settings in the Reclaimation page before configuring the job here.<br><br>**Rightsize**:<br><br>1. Downsize oversized VMs. When you select this option, you must select the rightsize resource type, and the downsizing limit amount. You can select the checkbox to include idle VMs in the rightsizing.<br>2. Scale-up undersized VMs. When you select this option, you must select the rightsize resource type.<br><br>**Note:**<br><br>VCF Operations does not check if the VM hot add/ remove setting is enabled. If the VM power off is not allowed, then the action will fail. You will find the error in Recent tasks and in the logs.<br><br>**Actions**<br><br>• **Adapter Type**: Select a public cloud or vCenter adapter from the drop-down list. Options are, vCenter, GCP, AWS, Microsoft Azure. |

| Property | Description |
|---|---|
| | • **Object Type**: Select the object from the drop-down list on which you want the action to be performed. Options are, Virtual Machine, Host System, Cluster Compute Resource.<br>• **Action**: Start typing the name of the action, or select an action from the drop-down list. The options are as follows: |

| Adapter Type | Available Action |
|---|---|
| vCenter | • Power Off VM<br>• Power On VM<br>• Reboot Guest OS For VM<br>• Suspend VM |
| GCP | • Power Off CE Instance<br>• Power On CE Instance<br>• Reboot CE Instance |
| AWS | • Power EC2 Instance<br>• Power On EC2 Instance<br>• Reboot EC2 Instance |
| Microsoft Azure | • Power Off Azure Virtual Machine<br>• Power On Azure Virtual Machine<br>• Reboot Azure Virtual Machine |

**Note:**
If the number of resources for a job is ten or less, then the job runs at once. If the number of resources is more than ten, then the jobs run in groups of ten, in parallel.

4. Click **Next**.
5. In the second step of the wizard, select scope of the object which contains the VMs on which VCF Operations must run the automation jobs.

   **Note:**

   - When you select scope for **Additional Actions**, the objects that you drag and drop must be either of the same object type, or the ancestor object (that will serve as a container) of the object type you have selected in the previous step. For example, if you selected **Host System** in the previous step, you need to select either a Host System object or an object that is higher in hierarchy (Cluster Compute Resources, Datacenter etc).
   - VCF Operations ignores object types which do not match the object type that you selected in the previous step. Invalid object types can be object of descendant object types, objects from a different management pack/ solution, or from unrelated object hierarchy.

   a) Drag and drop the object type to the left pane.
   b) To delete members, click the X icon.
6. After you have dragged & dropped the objects for the action, click **Preview Scope** at the bottom right corner to see on which objects the jobs will potentially be executed. This list may be different after you apply some filter from the **Filter Criteria** page.

   **Note:**
   The final objects list on which the actions will be run can be seen by clicking the **Preview Scope** button for the relevant job in the **Schedule** tab.

7. Click **Next**.
8. In the **Filter Criteria** step of the wizard, you can create rules using which VCF Operations filters objects on which the jobs are run. If you do not create a rule, all the VMs within the scope of the selected object type are affected.
   a) In the **Set Filter Criteria** section, create rules using a combination of metrics, relationship, property, object name or tag values and logical expressions.
   b) You can add more than one criteria by clicking either the ADD ANOTHER CRITERIA SET or ADD buttons. When you click ADD ANOTHER CRITERIA SET, VCF Operations creates an OR logical expression between the criteria sets. When you click ADD button, VCF Operations creates an AND logical expression between the criteria.
9. Click **Next**.
10. In the **Schedule** step of the wizard, configure a schedule for the action to run.

| Property | Description |
|---|---|
| **Start Date** | Set a start date which is on, or after the current date, for the job to start. Select a date from the calendar displayed on the page.<br>**Note:**<br>There will be a delay of up to five minutes for a job to run. The actual start time for an action also depends on the action itself and the number of target objects involved. |
| **Time zone** | For the start time and date to be calculated for the job, select a time zone. Choices are:<br>• Browser - based on the current location reported by the browser.<br>• Host - based on the current location of the host machine.<br>• GMT based time zone - Based on a location calculated as per UTC+0. |
| **Start Time** | Select a start time for the job. The drop-down menu provides options in five minute intervals, starting closest to your current browser reported time. |
| **Recurrence** | Set a recurrence for the job. The choices are:<br>• **One-Time**. No further configuration is possible.<br>• **Daily**. Set the recurrence in days. Set how frequently it must run by providing a value in **Run Every** field.<br>• **Weekly**. Select the days of the week when you want the job to run, by clicking the day of the week abbreviation.<br>• **Monthly**. Select the months when you want the job to run, by clicking the month abbreviation. By default, all the months are selected. For the months that you select, you can configure the job to run:<br>– On specific days of the month, by clicking the number. Or, the last day of the month, without specifying the exact date, by clicking **Last**.<br>– On the specific number of the week (first, second, third, fourth or the last) in the month, combined with the specific day of the week.<br>You can make multiple selections for each of the options in the drop down menu.<br>For the **Daily**, **Weekly**, **Monthly** options, you can set when the job must end based on a date, or the number of occurrences. |

   a) In the **Notifications** section, select the **Receive Updates on Job via Email** check box to receive notifications two hours before the job is set to run and after it has been executed. For the email to be sent, you must also select the

email outbound plugin from the drop down menu, and enter the email address to which the email must be sent. If you have not created an email outbound plugin, see the topic, Outbound Settings in VCF Operations.

**Note:**
You can send updates via email to only one email ID.

11. Click **Create** to complete the steps in the wizard and create the job.

## Create Job from Reclaim or Rightsizing

You can create an automation job based on the recommendation provided by VCF Operations in the Reclaim or Rightsizing pages. You cannot create an automation job outside of the context provided by VCF Operations here. Use Automation Central for that.

1. Do one of the following:
   a) After you log in to VCF Operations, from the navigation bar at the top, click **Manage** and in the left navigation pane, click **Capacity**. Click **Optimize** and then click the **Reclaim** tab.
   b) After you log in to VCF Operations, from the navigation bar at the top, click **Manage** and in the left navigation pane, click **Capacity**. Click **Optimize** and then click the **Rightsizing** tab.
2. In the Reclaim or Rightsizing pages, do the following
   a) Click the data center that you want to optimize.
   b) In the table heading that displays, Select the types of VMs that you want to optimize.
   c) Click the name of a listed cluster to show its VM list.
   d) Select the checkbox next to the VM that you want to optimize.
   e) Click **SCHEDULE ACTION**.
3. In the **Create Schedule Job** dialog box that opens, configure the following parameters:

| Property | Description |
|---|---|
| **Job Name** | Provide a name for the job. This information is displayed in the calendar in the Automation Central page. |
| **Job Description** | Provide a description for the job. |
| **Start Date** | From the date picker, select a date when the automation job should start. |
| **Time of Day** | • From the time picker, select the start time for the job.<br>• From the drop down, select the time zone when the time that you selected is valid for. |
| **Receive updates on Job via Email** | Select this checkbox if you have an email server configured, and you want to receive email notification about the status of the job. Notifications are sent two hours before the execution of the job. |
| **Notification Method** | If you selected the previous option, select the email outbound plugin from the drop down menu, and enter the email address to which the email must be sent. |

4. Click **Create**.

The automation job is created, and is available in the Automation Central page. From there, you can preview, edit, or delete the job.

**Note:**
The scope is not editable since the objects on which the job should be run have been already selected from the Reclaim/Rightsize page.

# Configuring and Analyzing Logs

VCF Operations provides capabilities to collect, parse, modify, process, and analyze logs collected from various VCF components. The prerequisite is the deployment of the log management component. VCF provides an integrated user experience for log analysis. You can view and analyze logs from the VCF Operations console.

# Overview of Log Management

Log Management has evolved from Aria Operations for Logs. Log Management is now integrated with VCF Operations.

Log Management component architecture has evolved significantly across recent releases to deliver tighter integration, higher performance, and simplified operations.

- Aria Operations for Logs (Version 8.x): The legacy, standalone appliance-based solution originally deployed as part of the Aria Suite.
- VCF Operations 9.0: Logs experience was converged into VCF Operations while the logs platform remained separate. This release rebranded the standalone solution and introduced native integration with VMware Cloud Foundation, delivering drastically improved scale and performance.
- VCF Operations 9.1: The latest architecture that comes with fully integrated Logs platform. Log Management is now a built-in, containerized core service running natively within the VCF Management Services Platform. The entire logging user experience, including deployment lifecycles, centralized configuration, access control, and alerting, is fully consolidated into VCF Operations.

# Log Collection Architecture

The centralized log collection architecture offers benefits such as granular configuration and cross-data center collection across various VCF components. To enable this capability, the Log Management component should be installed. Installaing the Log Management component is a Day-N operation, done via the lifecycle process, which automatically integrates it with VCF Operations. VCF Operations provides centralized management for log collection and supports diagnostic features that rely on these logs.

### Overview of Log Management Architecture

Log Management replaces Aria Operations for Logs, providing a comparable set of features and capabilities to what was previously offered. Log Management offers greater scalability than Aria Operations for Logs.

Log Management adopts OpenSearch and focuses on enhanced built-in security, better handling of resiliency during failures, and the ability to scale to much larger cluster sizes than was possible with Aria Operations for Logs.

Log Management runs within VCF management services. There is no longer a separate user interface for Log Management. All the functionality is available within VCF Operations. Content packs have been eliminated and replaced by content integrated into management packs. All lifecycle functions for Log Management, such as deployment, patching, upgrading, and resizing persistent volumes, are standardized based on VCF management services workflows. A break-glass UI provides access to the stand-alone interface, for emergency scenarios when VCF Operations is not accessible.

The deployment architecture of Log Management consists of three main service types within a VCF management services cluster: the gateway pod (Envoy), the log processor service, and the log store. The Envoy pod acts as the gateway, responsible for accepting all traffic from various log sources and communicating with external services. The log processor service is the basic engine of the platform, interacting with the log store (OpenSearch) and handling ingestion, querying, and all log management activities. The log store uses OpenSearch to index and persist all log data, including configuration data.

The Envoy pod acts as the gateway, responsible for accepting all traffic from various log sources and communicating with external services. In HA mode, the gateway is deployed with a single instance per VIP/FQDN. In non-HA mode, a single gateway handles all VIPs. Traffic ingestion flows from the gateway to the log processor and finally to the log store. The log processor implements rules for masking, forwarding, filtering, and creating with partitions, while the log store handles the indexing of log messages, persisting data, and implementing alerts and queries.

### Centralized Configuration Management

The log collection configuration is stored in the Log Management cluster, but updates are always initiated through VCF Operations. If you have remote VCF instances and need to send log data to the main, central Log Management deployment, you can deploy a Unified Cloud Proxy. The Unified Cloud Proxy acts as a secure log forwarder that aggregates and routes data from your remote environments to the primary cluster.

Irrespective of whether logs are forwarded via the Unified Cloud Proxy, or sent directly to the Log Management cluster, the interface for providing centralized log collection is through VCF Operations for the components which follow the log standard introduced in 9.0.

### Unified Cloud Proxy

Unified Cloud Proxy plays a key role in collecting logs from multiple data centers. It works as follows:

1. VCF Operations requests credentials.
   a. VCF Operations requests credentials from Log Management for the log forwarder.
   b. This request includes the Cloud Proxy ID.
2. Credential transmission.
   a. The credentials and Log Management FQDN (Fully Qualified Domain Name) are sent to the Cloud Proxy.
   b. This data is encrypted.
3. Log forwarder setup.
   a. The log forwarder decrypts the payload and establishes a connection with Log Management.
4. Configuration updates.
   a. Any future configuration updates are sent via this established connection.

For more information about the types of Cloud Proxy deployment, see the topic, Collecting Data with Cloud Proxy in VCF Operations.

## Getting Started with Log Management

Log Management (formerly VCF Operations for Logs, and before that, VMware Aria Operations for Logs) collects, analyzes, and visualizes logs across your VMware Cloud Foundation fleet.

As of VCF 9.1, Log Management is a built-in, containerized core service that runs natively within the VCF Management Services Platform and is fully integrated into VCF Operations. There is no longer a separate logs UI for normal use.

### What Log Management Provides

- A centralized log collection framework for vCenter, ESX, NSX, VCF Automation, VCF Operations, VCF Operations HCX, VCF Operations for networks, Identity Broker, SDDC Manager, and other VCF management services components.
- An architecture built on OpenSearch, giving greater scale and resiliency than the legacy Aria Operations for Logs appliance.
- Log search, filtering, saved queries, charts, log comparison, and log-based alerts.
- Log processing controls - masking, filtering, forwarding, and partitioning with configurable retention.
- Agents for Linux (filelog, journald) and Windows (via Fluent Bit) log collection, plus native syslog and CFAPI ingestion.
- Role-based access control down to which logs a user can see (data sets/scopes).
- A Log Management Health Overview dashboard, plus a drill-down dashboard for advanced troubleshooting.
- Log Assist, for generating and uploading support bundles to Broadcom Support.
- A standalone “break-glass” UI for emergency access if the VCF Operations console itself is unreachable.

### Choose a Deployment Model

Log Management is added to your VCF fleet as a Day-2 operation, and at deployment time you choose one of three models.

| Model | Best for | Key attributes |
|---|---|---|
| Simple | Test/dev environments | Single replica; smallest footprint; relies on VCF management services and vSphere HA to restart on failure; no application-level HA |

| Model | Best for | Key attributes |
|---|---|---|
| High Availability | Default for production/fleet deployments | 3–19 replica cluster behind an integrated load balancer; full-to-partial service maintained on node failure |
| Multi-Instance | Large-scale or bandwidth-limited/ segregated environments | One VCF Operations–integrated instance plus additional independently managed instances (each Simple or HA); non-integrated instances run standalone on Aria Operations for Logs 8.18 |

All three are deployed in the same way (through VCF Operations), and all can scale up (bigger nodes) or out (more replicas) later, but never back down.

## Before You Deploy Log Management

| | |
|---|---|
| **Timing** | Log Management is not part of the day-zero install. Deploy it after your initial VCF/vSphere Foundation provisioning is complete. |
| **Networking** | Decide your FQDN(s) and IP address(es) up front. At least one Virtual IP (VIP) + FQDN is required at deployment; more can be added later, but your SSL certificate must include every VIP's FQDN in the SAN field before you can create additional VIPs. |
| **Capacity** | Log Management runs on the VCF management services runtime cluster in your fleet's first VCF Instance, so that cluster needs spare CPU/memory/IP-pool capacity.<br><br>VCF management services auto-scales *out* to accommodate Log Management, but scaling *up* (bigger node size) should be scheduled in a maintenance window. |
| **Storage** | Log data is stored on persistent volumes in the management services runtime cluster's default datastore. Plan datastore capacity and IOPS for your ingestion rate and retention. To use other datastores, migrate log store volumes with vSphere CNS. See Migrating Log Management log store container volumes in vSphere. |
| **Sizing** | Estimate Events Per Second (EPS) as roughly 250 × number of ESX hosts (adjust for high-volume sources like firewall logging), plus expected connections and retention needs. This drives your size/replica choice. Use the VCF Operations Sizing Estimator for sizing requirements. |
| **Retention/archive planning** | Decide whether you need long-term archiving. If so, you need an NFSv3 share or S3-compatible endpoint (up to 5 external storage locations). |
| **Backups** | Configure an SFTP location so Log Management's configuration is backed up automatically as part of VCF management services. |
| **Security** | FIPS mode is on by default. Hosts with CPUs that don't support FIPS cipher acceleration may see reduced ingestion capacity. |

## Deploy Log Management

For more information, see the topic, Deploy Log Management.

## Connect Your Log Sources

- Log collection is on automatically for components that are hosted on VCF management services (VCF Automation, Identity Broker, Log Management itself) and cannot be disabled.
- For the following components, you must explicitly activate log collection on that component's adapter (**Administration** > **Integrations** ).
  - vCenter
  - NSX
  - VCF Operations HCX
  - VCF Operations for networks
- Choose whether each source sends logs directly to the Log Management VIP or via a Cloud Proxy (recommended for remote sites as it buffers and optimizes traffic, but always round-robins across all VIPs).

- Version notes: vCenter 9.1.x uses the new Logs Agent (supports custom filtering/fields). Earlier vCenter versions fall back to rsyslog without that support. Windows hosts need Fluent Bit, configured to forward to the Log Management VIP on port 9543.

For more information, see Configuring Log Sources for Log Management.

### Configure Core Log Processing Settings

All under **Operate** > **Administration** > **Configurations**

| | |
|---|---|
| **Log Partitions** | Segment logs by filter criteria with per-partition retention (2 days to limitations of the storage) and archive configuration. Audit and Default partitions always exist; up to 9 custom ones can be added. For more information, see Configuring Log Partitions. |
| **Log Masking** | Redact sensitive fields/text matching a filter. For more information, see Log Masking. |
| **Log Filtering** | Drop unwanted logs before indexing (useful when a source cannot filter itself, for example, syslog). For more information, see Log Filtering. |
| **Log Forwarding** | Relay filtered/tagged logs to up to 10 external syslog/log-management destinations. For more information, see Log Forwarding. |
| **External Storage** | Register NFS or S3 targets used for archiving, import, and export. For more information, see Configuring External Storage. |
| **Integrated Load Balancer** | Manage VIPs/FQDNs; add more when you need extra ingest capacity or want to tag logs by source. For more information, see Integrated Load Balancer. |
| **Agents and Agent Groups** | Manage Linux/Windows collector agents, authentication secrets, and grouped configuration pushes. For more information, see Overview of Log Management Agents. |

### Analyze and Troubleshoot with Logs

- The **Logs** page (**Operate** > **Logs**) is where you search, filter, build fields, save queries, and chart results.
- **Compare Logs** lets you line up results from up to four queries side by side.
- Logs also surface per-object in **Inventory** > **Logs**and in the **Workbench**, so you can correlate log entries with metrics during an investigation.
- You can define log-based alerts from saved queries, and combine log symptoms with metric symptoms in the same alert definition.
- Several core components (vCenter, ESX, NSX, HCX, Operations for Networks, VCF Operations, Identity Broker, VCF Automation) now emit a standardized, structured log format, which simplifies both manual troubleshooting and automated parsing.

### Control Access to Logs

Log access control is unified into standard VCF Operations RBAC:

1. Define a Data Set (**Access Control** > **Scopes** ) — a set of log filters (for example, “hostname contains x”).
2. Check role permissions (Access Control > Roles) — make sure that the assigned role has permissions that you need (Log Processing, Log Forwarding, Log Collection, and so on).
3. Assign the Scope and Role to a user or group.

A Scope can independently carry an **Object Scope** (which infrastructure objects are visible) and a **Log Data Set** (which log data is visible). Assigning one does not automatically restrict the other.

### Monitor the Health of Log Management

Use the **Log Management Health Overview** dashboard (**Operate** > **Dashboards** > **All**) as your first stop for both active alerts and general health checks. It is organized into four areas:

- Ingestion,
- Retention
- Availability
- Operation

Each of these dashboards has guided remediation steps. A disabled-by-default drill-down dashboard exposes per-component (gateway/processor/store) metrics for deeper troubleshooting, and a companion VCF management services cluster health dashboard helps you rule out resource contention on the underlying platform.

**Get Support When You Need It**

- If the VCF Operations console itself is down, use the standalone break-glass U at the Log Management FQDN to search logs directly.
- From that same standalone UI, you can generate a cluster-wide support bundle.
- For day-to-day support cases, use Log Assist (requires Connected Mode licensing and a Cloud Proxy with outbound access to `eapi.broadcom.com`) to auto-generate and upload log bundles plus diagnostic findings straight to a Broadcom support case.

**If You are Upgrading from an Older Logs Product**

Log Management is never an in-place upgrade. It is always a fresh 9.1 deployment plus a configuration import:

- From an existing 9.0 VCF Operations for Logs instance: credentials are auto-detected and imported.
- From Aria Operations for Logs 8.18.x: you enter the FQDN/credentials manually.
- After import, you get a 90-day query federation window against the old cluster, an on-demand Data Migration Utility, and a separate Log Data Transfer tool for historical data.
- Custom content (dashboards, alerts, queries) does not migrate automatically. Export it as a Content Pack and run it through the CLI conversion utility to produce a Management Pack.

## What's New in Log Management

Log Management brings several enhancements to how you can handle logs from different VCF components.

- Monitoring
  - Detection and surfacing of issues based on logs, alerts, and notifications.
  - Visual analytics provided through dashboards and reports.
- Troubleshooting
  - Log pattern detection and pattern trends.
  - Log compare.
  - Capabilities to detect outliers or the absence of logs.
- Security Operations (Log Administration):
  - Data set definition scope.
  - Merging the data set within the VCF Operations scope, which aligns with user role, group creation, and user role assignment.

    Access control, which allows for data set restrictions based on a log scope to define what you can or cannot access. Roles have also been enhanced to include log pages and other related aspects.
  - Role-based access control (RBAC).
  - Log segregation and retention.
- Log Processing Rules
  - Log Masking: Masking critical fields or text for security sensitivity. This requires providing the field or text to mask, the pattern on which to apply the masking (for example, the entire field or a portion), the mask value, and the filter criteria.
  - Log Forwarding: Forwarding a select set of logs or security audit logs based on filter criteria to a central security product or third-party endpoint. This can also forward tags.
  - Log Filtering: Logs are filtered out or dropped based on a filter criteria from the source. This is useful when the sender cannot filter the logs themselves, for example, with syslogs.
  - Log Archival: Archiving logs for compliance and regulatory needs and primary storage offloading. S3 Endpoint support for archive destinations is a new capability.
  - Log Partition: Logical segregation of logs based on various criteria such as retention, routing, or filtering. You can define the retention period (from 2 days to forever) for any specific partition.
  - Audit Record partition for audit logs.

- Logs Page. Workflow-related changes and fine-tuning were brought in to make the page more usable and easier to consume.
  - Saved queries, direct text search, and additional filters, including partition selection and a time range.
  - A quick link to Log Compare is available.
  - An export function allows exporting query results in JSON format to external storage (NFS) or local storage (if the log size is 20,000 or fewer logs) for consumption or analysis.
  - You can view the distribution of data for any field (for example, app name) within the selected time range.
  - A fields library allows you to view all existing fields, including system-defined indexed fields and discovered non-indexed fields, which customers can choose to index for performance reasons. You can also rediscover fields to get rid of old ones.
  - Logs migrated from a previous version are detected, and a time window for accessing those logs is retained in the current release, accessible under a legacy log integrated partition. You are encouraged to reconfigure log sources through the VCF adapter and vCenter integrations.
- Global Settings Updates
  - New settings in the Global Settings page for agent authentication and for event cluster management. As part of security hardening settings, by default, SSL ingestions are enabled for CFAPI and Syslog.

## Deploy and Upgrade Log Management

Log Management is not an in-place upgrade from Aria Operations for Logs. The process starts with a new installation of the Log Management component via the VCF Operations console. The Log Management component is not part of the day-zero installation flow, so you must deploy it after the initial VCF provisioning and installing day-zero components. During the installation wizard, you must provide at least one FQDN and corresponding IP address. The wizard also presents an option to import settings from Aria Operations for Logs and while importing settings from VCF Operations for logs.

### Configuration and Settings Migration

A key part of the upgrade is migrating configurations from the Aria Operations for Logs 8.18.x and VCF Operations for Logs to the new Log Management installation.

- From 9.0**:** If you are upgrading from VCF 9.0 with an existing integrated VCF Operations for Logs instance, the system automatically detects the old credentials via the service registry. These settings are then automatically imported to the new Log Management, eliminating the need for manual input of the address and credentials
- From 8.18.x**:** If you are upgrading from Aria Operations for Logs 8.18.x, then you must manually enter the FQDN and admin credentials of the old Aria Operations for Logs instance in the import flow.
- Configurations Migrated**:** During this import flow, the system pulls specific configurations from the Aria Operations for Logs and adds them to Log Management, including log filters, log masking, and log forwarder rules. Existing log collection configurations are also integrated into Log Management.
- Report Generation: After the installation and configuration import are complete, a PDF report is generated. This report lists all the configurations that were successfully pulled from the legacy Aria Operations for Logs and added to Log Management. It also includes a list of configurations that cannot be migrated automatically (for example, Datasets) with instruction on how to move those over post-import.

### Data Access and Migration

The upgrade process focuses on configuration migration but provides a mechanism to access old data:

| | |
|---|---|
| **Query Federation** | After installation, Log Management creates an integration with Aria Operations for Logs. This integration is used to provide federation of queries for a period of time, specifically 90 days after the Log Management installation. During this window, you can query your Aria Operations for Logs data from the Logs page in VCF Operations. If you select a legacy Aria Operations for Logs partition, Log Management forwards the query to the legacy instance and fetches the data. |
| **Data Migration Utility** | There is an on-demand data migration utility that you can use anytime you want to migrate log data from Aria Operations for Logs to Log Management. This is a long-running process due to the potential volume of log data. |

### Post-Upgrade Behavior

Following the VCF provisioning, when you navigate to any log capability page in VCF Operations before Log Management is installed, you see a notice prompting you to install the Log Management component.

For upgrade scenarios, specifically from 9.0, where partial integration existed, the day-zero pages are shown to enforce the installation of Log Management. Until the installation is complete, no log data is available in VCF Operations, and accessing log capabilities will redirect you to the installation flow. After the Log Management component is successfully installed, it will appear in the component list, and the option to deploy it will no longer be available, as there is one-to-one mapping between VCF Operations and Log Management.

As part of Day-N operations, you can scale up (vertical, increasing size) and scale out (horizontal, increasing replicas) the cluster. Scale-down operations (decreasing size or number of replicas) are not possible using the VCF Operations UI. You can also scale up the log store storage size as a Day N operation.

### How to Deploy or Upgrade

- For information on how to deploy Log Management, see Deploy Log Management.
- For information on how to upgrade to Log Management, see Upgrade to Log Management 9.1.
- To copy historical logs from VMware Aria Operations for Logs 9.0, integrated VCF Operations for Logs 9.0 to Log Management, see Log Data Transfer.
- To configure log forwarding from standalone single/multiple Aria Operations for Logs 8.18.x instances to Log Management, see Configuring Log Forwarding.

## Log Data Transfer

You can transfer log data for up to 90 days from Aria Operations for Logs 8.x and VCF Operations for Logs 9.0 and to VCF 9.1. The migrated logs are stored in the Log Management cluster. You must deploy Log Management before you can proceed.

### Why Transfer Log Data

VCF does not permit integration of VCF Operations with Aria Operations for Logs. If you had previously integrated Aria Operations for Logs and Aria Operations, and you have upgraded to VCF, then you must use the Log Data Transfer feature to transfer ingested logs to Log Management.

When you set up operations-logs as a log forwarding destination in Aria Operations for Logs, logs which are already ingested by Aria Operations for Logs are not forwarded to VCF Operations. To forward already ingested logs, use the Log Data transfer functionality in VCF Operations.

### How to Transfer Log Data

After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Control Panel**. Under **Content and Support** section, click **Logs Data Transfer**. If you have not set up any transfer, click the **INITIATE TRANSFER** button and configure the authentication details about the VMware Aria Operations for logs 8.x or VCF Operations for Logs 9.x appliance. You can select the duration of logs to transfer from the drop-down. Transfer logs from the last 10 days to start with.

After you initiate the task, you can check the status of the transfer from the **Logs Data Transfer** card at any time.

**Note:**

- Not all data buckets may be copied unless Log Management has enough free disk space. It is recommended to run this check manually prior to starting the migration to guarantee that all logs from the VMware Aria Operations for logs 8.x or VCF Operations for Logs 9.x instance are migrated to VCF Operations. Before starting the migration, know the location of the live storage in VCF Operations, and the volume of logs stored in the live storage of the old instance.
- Data for any selected interval is fully re-imported. Check the audit record to avoid redundant transfers.
- All source nodes of the Aria Operations for Logs instance must have the same SSH credentials as each other, and be reachable via port 22 from the Log Management nodes, otherwise the migration is unsuccessful.

## Log Partitions and Searching Older Partitions

Log Management provides with you with options to create partitions and query them. You can create multiple custom partitions using specific filtering criteria to segregate log data and perform targeted queries against individual partitions. For upgrade scenarios where a legacy cluster FQDN is specified, the system supports querying from legacy partitions for up to 90 days. Finally, you can query re-imported archive data. To query archived logs, the data must first be re-imported into the platform using the archive import workflow, which creates a searchable archive partition available for selection. Querying is performed on one partition at a time.

### Aria Operations for Logs or VCF Operations for Logs 9.x Logs Partitions

In a brownfield deployment, you upgrade from an existing Aria Operations for Logs or VCF Operations for Logs 9.x instance. You can connect the newly installed Log Management instance with a VMware Aria Operations for logs 8.x or VCF Operations for Logs 9.x instance to the new Log cluster instance as part of the upgrade workflow, and not later on. After this configuration is complete, the **Logs** page in VCF Operations displays a banner which serves as a notification that the connection with the VMware Aria Operations for Logs 8.x or VCF Operations for Logs 9.x instance will expire in 90 days.

You must complete all data and settings, such as datasets, before 90 days. After 90 days, VCF Operations will not be able to query data from older versions.

The connection with Aria Operations for Logs makes it possible to search for logs in legacy partitions directly from the **Logs** page in VCF Operations. This connection with VMware Aria Operations for Logs 8.x or VCF Operations for Logs 9.x instance will automatically be deleted after 90 days, at which point the banner will be hidden, and these legacy partitions will no longer be available for searching. For more information, see Configuring Log Partitions.

### Archive Locations

You can import logs from from archives in a configured external stroage location (S3 or NFS), and search against these locations. This can be found in the **Log Partition** tab under **Administration** > **Configurations** > **Log Processing**. To query these archived logs, you must use the archive import workflow to re-import the data into the platform. Once re-imported, the data resides in a searchable archive partition that can be selected for querying. Note that only one imported log archive can be active for querying at a time. To search a different archive, you must purge the current one and repeat the import process.

You can restore the archived information back to Log Management. VCF Operations allows for restoring archived logs not only from Log Management archive locations but also from Aria Operations for Logs archived locations. It is recommended to import the logs with a small time range because if the import logs fill the storage more than 80%, the task fails. When importing from Aria Operations for Logs archives, only NFS storage is supported. You must provide the mounted path and specify the time range of the archived data that you wish to import.

Initiating an import generates a task that can be monitored under Log Tasks which can be found under **Administration** > **Control Panel** > **Log Import/Export Tasks**. Once the logs have been successfully imported, you can search against this archived data from the **Logs** page using the **Import Partition** drop-down menu. By applying the archived logs option in this section, you can view all the logs that were imported from the specified time range. For more information, see Archive Log Import.

## Configuring Log Partitions

Log partitions enable the segmentation of log data through defined filter criteria and support specific retention and archival policies. This segmentation facilitates efficient log management by allowing for different retention periods and ingestion orders across multiple custom partitions. Separate partitions can be configured to archive to specific NFS or S3 locations. Archiving lets you shorten retention in the log store, which reduces storage use and improves query performance, while the older data stays available in the archive. Each partition's retention policy ensures that logs are either kept until storage reaches the 80% threshold and then are automatically purged. From the **Log Partitions** page, you can create partitions, edit, clone, activate, deactive, and delete partitions.

The order of evaluation for these rules is top-to-bottom. Partitions are processed based on an ingestion order, which you can modify. Since the first matching partition rule takes precedence, you can change the order to ensure logs flow to the

desired partition first. The default partitions, such as Audit records and Default partition cannot be modified. The Audit records partition is always the first filter covered and the default partition the last.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Then click the **Log Processing** card.
2. Click the **Log Partition** tab.
3. The Log Partitions interface presents a tabular view of defined partitions with key attributes.
4. Click **ADD** to add a new Log partition. Or click the vertical ellipses to edit an existing partition. Enter the following values:

| Option | Description |
|---|---|
| **Name** | Provide a name for the partition |
| **Retention Period** | Set the retention period in days. Use 0 for indefinite retention (storage-limited retention). The minimum retention period for index partitions is 1 day and maximum periods vary by partition type.<br><br>Once the specified retention period (set in days) is met, the system automatically removes the logs from the disk. If the retention period is set to zero, logs are kept indefinitely and not automatically removed based on time. Regardless of the set retention period, logs may be removed earlier if the disk reaches a certain capacity threshold. In this case, the system starts deleting the oldest data first to ensure it can continue serving new requests. |
| **Enable Configuration** | Select the checkbox to enable the configuration. This deterimines if the log partition is active or not. |
| **Enable Archive** | Select the checkbox to enable archiving. If you enable archiving, you must enter the NFS or S3 location where the log data is archived.<br><br>Logs are archived the next time the archiving process runs. They are not held until the retention period expires. The archiving process runs whenever the index is rotated, which is every 24 hours, or sooner if a large volume of logs is ingested. |
| **Source** | If you have enabled archiving in the previous step, you can select the external storage. Specify the host source and storage path for long-term storage if archiving is required. In the text box, enter the NFS or S3 location where you want to store the archived data, in folder structure format that your organization maintains. S3 storage is recommended to archive the logs. Or, select the location from tghe dro-down list oif the sources are already defined.<br><br>The storage path must be a valid mount path. The host must be defined in **Configurations** > **External storage**.<br><br>Before configuring an NFS share for import, export, or archive operations, ensure the target directory has the correct ownership and permissions and the path specified is relative to the mount point, and does not start with a leading "/".<br><br>To allow the system to write data successfully, the mounted NFS directory and its subdirectories require specific permissions.<br><br>• Ownership: The directory must be created by the `root` user.<br>• Minimum Permission Level: `447` (Read/Write/Execute for Owner and Others).<br><br>If your NFS directory does not meet these requirements, update them using the following commands on your NFS server:<br><br>`sudo -i` |

| Option | Description |
|---|---|
| | `chmod -R 447 /path/to/your/directory` |
| **Storage Path** | Folder to put the archives, starting from the root of the selected source (provided without a leading "/") |
| **Filtering** | Add one or more filters to refine the logs that you want to store in the log partition. Filters can include key-value matches or Exists/Does not exist on fields such as hostname, appname, and static indexed fields.<br><br>**Note:**<br><br>The logic that is used in the filter preview is different from the logic that is used when filtering in the **Logs** page. For more information, see Log Management Filters.<br><br>**Note:**<br><br>The filtering option is not available when you edit the Audit and Default partitions. |

5. Click **PREVIEW** to preview the log partition or **CREATE** to save it.

The log partition configuration appears in the **Log Partition** tab with information. To modify a single row, click the vertical ellipses. For bulk activation, deactivation or deletion, select multiple rows and click the horizontal ellipses.

**Note:**

For information on Importing Log Archives, see Log Partitions and Searching Older Partitions.

## Migrating Log Management Log Store Container Volumes in vSphere

You can migrate Log Management log store persistent container volumes from one datastore to another using the vSphere Cloud Native Storage (CNS) migration feature. In VMware Cloud Foundation (VCF) and VMware vSphere Foundation (VVF) environments, runtime services cluster VMs are placed on a single datastore. If you face capacity limitations, like max node size, you can migrate the log volumes using the workaround that is provided here. You should note the limitations and reapply the workaround in case of scale and DR actions. Relocating these volumes across multiple target datastores balances IOPS while maintaining continuous log ingestion, data integrity, and platform functionality.

Before migrating log store volumes, ensure the following conditions are met:

- Environment: A VCF Operations 9.1 environment with Log Management deployed on a VCF Management Services (VCFMS) cluster is active and healthy.
- Storage Accessibility: At least two datastores (the source datastore and one or more target datastores) must be fully accessible from all ESX hosts underlying the VCF Management services.
- Capacity: Target datastores must have sufficient free capacity to accommodate the migrated persistent volumes.
- Permissions: Your vSphere Client user account must possess administrative permissions to view and migrate container volumes.
- Establish Baselines:
  - Record the baseline mapping of your current datastore layout and identify the specific volume IDs and sizes backing your log store.
  - Execute a baseline query in the the **Logs** page. Document the sample entries and total result counts for comparison.
  - Ensure active log ingestion streams (via agents and syslog) are operating smoothly.

Limitations and Constraints:

- Only single block volumes can be migrated.

- PMEM (Persistent Memory) datastores are not supported as migration targets.
- The VCF Management services worker node hosting the persistent volume will be locked during the CNS relocation process, meaning no other infrastructure control operations can be performed on it until the move completes.

1. Log in to the vSphere Client.
2. Navigate to the datacenter, cluster, or source datastore hosting your infrastructure.
3. Select the Monitor tab and click **Cloud Native Storage** > **Container Volumes**.
4. To easily isolate the log management volumes, click **Add Filter** and filter by the Kubernetes component label:

   ```
   Label: app.kubernetes.io/component:log-store
   ```

5. Select the specific log store persistent volume (PV) you intend to move and click **Migrate**.
6. In the **Migrate Volume** dialog box, select your preferred target datastore.
7. Review and acknowledge any compatibility warnings (such as storage policy mismatches or datastore inaccessibility), then click **Migrate**.
8. Monitor the migration progress under the **Recent Tasks** pane in the vSphere Client until the task completes successfully.

Once the vSphere migration task finishes, verify data integrity and workload continuity:

- In the Container Volumes view, confirm that the volume's location has updated to the target datastore and its Health Status returns to Accessible or normal.
- Browse the target datastore files to ensure the virtual disk backing the volume exists within the proper First Class Disk (FCD) directory or VM folder.
- Verify that the matching Kubernetes PersistentVolumeClaim (PVC) status remains Bound and shows no active pod scheduling errors.
- In the **Logs** page, re-run your baseline search query to verify that no log data was lost or corrupted during the migration window.

Important Operational Considerations

- **Scale-Out Operations:** During any post-migration cluster scale-out operations, newly added log-store node volumes will automatically attach to the default platform-managed services Datastore. Administrators must manually repeat this migration procedure if they choose to redistribute new volumes to preferred datastores.
- **Disaster Recovery (DR):** If a DR event occurs and the Log Management component is restored from a backup into a fresh VCF Management Services cluster environment, all custom disk placements are reset to the default single VCF Management Services Datastore configuration. You must execute this volume relocation procedure again after the DR environment is online to clear potential storage hotspots.

# Configuring Log Sources for Log Management

You enable Log analysis for vCenter, NSX, VCF Operations HCX, VCF Operations for networks, VCF Operations when you configure the adapter, and for Identity Broker, and VCF Automation when you deploy the component. You then fine-tune the log collection based on logical service grouping, granular log level filtering, and custom tagging.

### Log Collection for VMware Cloud Foundation Components

When you activate log collection on the vCenter Server Cloud Account or VMware Cloud Foundation pages, Log Management automatically begins collecting vCenter events, tasks, and alarms, alongside VMware ESX and vSphere Supervisor logs.

To collect logs for the vCenter instance, you must explicitly activate vCenter log collection on the **Log Sources** page.

The method used to collect vCenter logs depends on the version you are running:

- vCenter 9.1 and later: Log collection is performed using the Logs Agent, which supports advanced log processing.
- Earlier versions of vCenter**:** Log collection relies on rsyslog. When using **rsyslog**, custom filtering and extracted fields are not applied to the collected logs.

The following table outlines the VMware Cloud Foundation (VCF) components that support log collection and their required minimum versions.

| Component | Version Supported |
|---|---|
| VMware vCenter | 9.1 and later |
| VMware Cloud Foundation Operations | All versions |
| VMware NSX | All versions |
| VMware Cloud Foundation Operations for Networks | 9.1 and later |
| VMware HCX | 9.1 and later |

## General Configuration Features

The following configuration options are standard across most supported components:

**Logical Service Groups** Logs are now grouped into logical services rather than individual log paths. You can enable or disable these groups based on your requirements.

> **Note:**
>
> Audit Logs cannot be disabled and are always collected once log collection is activated.

**Log Level Filtering** You can filter logs by severity. The default setting is Info, but this can be adjusted (for example, to Debug) to increase or decrease log granularity.

**Custom Fields (Tagging)** You can define custom fields to tag logs originating from specific files. These tags are appended to the logs and are visible on the Analyze page for easier filtering.

**Reset to Default** This option is available to restore the original configuration if needed.

## Component Specific Log Collection Configuration

Adding a VMware Cloud Foundation account and enabling log collection for each instance of these adapters is recommended over adding the adapters and enabling log collection directly. For more information, see Configuring a Standalone VCF Account in VCF Operations.

**vCenter** You enable Log collection when the adapter is configured or after adding VMware Cloud Foundation. To enable log collection using the adapter, see Configuring a vCenter Account in VCF Operations.

**NSX** You enable log collection when the adapter is configured or after adding VMware Cloud Foundation. To enable log collection using the adapter, see Configuring the NSX Account in VCF Operations.

**VCF Operations HCX** You enable log collection when the adapter is configured.

**VCF Operations for networks** You enable log collection when the adapter is configured.

**VCF Operations** Log collection is enabled by default.

**Identity Broker** Log collection is enabled after the component is deployed in Fleet Lifecycle. For more information, see Deploy Identity Broker as a Day-N Operation.

**VCF Automation** Log collection is enabled after the component is deployed in Fleet Lifecycle. For more information, see Deploying VCF Automation as a Day-N Operation.

> **Note:**
>
> For NSX, the system does not report an active status. When log collection is functioning correctly for NSX, the status displays as **Received**.

## Managing the Logs which are Collected

After you enable log collection, you can manage the types of logs which the adapter collects. For more information, see Managing Collection from Log Sources.

**Upgrade Scenarios**

Log Collection configuration is not automatically updated after migration from a previous version of VCF Operations for logs, or Aria Operations for Logs.

The following configuration settings have their status migrated as part of the Log Management upgrade:

| Configuration Setting | Aria Operaions for Logs 8.18 | VCF Operations for logs 9.0 | Note |
|---|---|---|---|
| Agent Group | Yes | Yes | |
| Alerts | No | No | Report Only |
| Data Partitions | Yes | Yes | |
| Extracted Fields | Yes | Yes | Only custom extracted fields |
| Log Collection Configuration | No | Yes | Only migrated for Log Management 9.x |
| Log Filters | Yes | Yes | |

## Managing Collection from Log Sources

You can manage the types of logs that are collected, logical service grouping, granular log level filtering, and custom tagging.

Verify that you have the **manage** permission to configure log sources. You can configure permissions in the **Access Control** card when you navigate to **Administration** > **Control Panel**. Go to the **Roles** tab and select or deselect the permissions when you add or edit a role.

Verify that the Log Management component is installed. See the topic, Deploy Log Management for more information.

**Note:**

The logs generated by Log Management are also collected, but it cannot be modified or configured.

**Note:**

VCF Operations supports a configuration export and import functionality which allows transferring the configuration from one VCF Operations instance to another. The log collection configuration for the vCenter adapter instances is not included in the export and import.

1. To manage configurations, go to **Administration** > **Configurations**. Click the **Log Collection** card. This opens the **Log Sources** tab.
2. You see the following list of log sources:
   - vCenter
   - NSX
   - VCF Operations HCX
   - VCF Operations for Networks
   - VCF Operations
   - VCF Identity Provider
   - VCF Automation
   - VCF services runtime
   - SDDC Manager

   **Note:**

   For VCF Identity Providers, VCF Automation, and VCF services runtime, the log collection is always enabled and you cannot edit any settings.
3. For the individual components, manage the log collection.
   - Click the vertical ellipsis next to vCenter to edit the following log collection settings.

- For vCenter:

  **Note:**

  To transfer logs from VMware Aria Operations for Logs 8.x and VCF Operations for Logs 9.x, see Log Data Transfer.

| Option | Description |
|---|---|
| **Collect Logs directly in Logs Cluster** | Dropdown to select the VIP to use for log ingestion. |
| **vCenter Server events and alarms collection** | Select the checkbox to enable the collection of vCenter specific events and alarms. |
| **vCenter Log Collection** | Select the checkbox to activate collection of vCenter logs. |
| **Log Filters** | **Log Level :** Dropdown to filter logs by severity (for example, Trace, Info, Debug).<br>**Service Groups:** Toggle to enable or disable specific logical groupings of log paths. |
| **Fields** | Options to **Add New Field** or **Clear All**. Used to tag incoming logs with custom metadata for easier filtering. |
| **Log Types** | For each vCenter service, toggle the log collection and display the path to the log files being collected.<br>**Note:**<br>Audit log collection is mandatory and cannot be disabled. |

- For ESX, edit the following log collection settings:

| Option | Description |
|---|---|
| **Edit log collection configuration** | Select the checkbox to edit the further configuration options |
| **ESX logs** | Select the checkbox to activate collection. |
| **ESX Audit Logs** | Select the checkbox to activate collection. |
| **Syslog Protocol** | Select the protocol over which sylog is collection. Default is TCP over SSL. |

- For vSphere Supervisor, edit the following log collection settings:

| Option | Description |
|---|---|
| **Edit Log collection configuration** | Select the checkbox to edit the further configuration options |
| **Log Filters** | Select an option from the drop-down list. Logs will include the selected level and higher in severity. |
| **Fields** | Add fields with predefined values to events, alarms and logs coming from vSphere for easier querying. |
| **Service Collection** | For each vSphere Supervisor service, toggle log collection and the file path. |

4. For NSX, VCF Operations HCX. And VCF Operations for networks edit the following log collection settings:

| Option | Description |
|---|---|
| **Collector Configuration** | Select the destination cluster for NSX logs. |
| **Log Collection configuration** | Toggle to collect the logs configuration |
| **NSX Log Collection** | Checkbox to activate or deactive collection of logs for the NSX adapter. |
| **Fields** | Add or manage custom fields. |

| Option | Description |
|---|---|
| **Predefined Log Filters** | Log Level: Select an option from the dropdown to filter logs by severity (for example, Trace, Info, Debug). |
| **Service Collection** | For each NSX service, toggle log collection and the file path.<br>**Note:**<br>Audit log collection is mandatory and cannot be disabled. |

5. For VCF Operations, edit the following log collection settings:

| Option | Description |
|---|---|
| **VCF Operations Log Collection** | Toggle to activate the collection.<br>**Note:**<br>For fresh setups, this is enabled automatically and cannot be fully deactivated. |
| **Log Filters** | Log Level: Select an option from the dropdown to filter logs by severity (for example, Trace, Info, Debug). |
| **Service Collection** | For each VCF Operations service, toggle log collection and the file path.<br>**Note:**<br>Audit log collection is mandatory and cannot be disabled. |

6. For SDDC Manager, log collection settings are enabled when you add the VCF Adapter instance. You can override or edit the following options:

| Option | Description |
|---|---|
| **Collector configuration** | Select the logs cluster to which you want to collect the logs in the **Collect Logs directly in Logs Cluster** setting. |
| **SDDC Manager Log Collection** | Activate or deactivate the SDDC Manager Log Collection. |
| **Log Filters** | Log Level: Select an option from the dropdown to filter logs by severity (for example, Trace, Info, Debug). |
| **Fields** | Add or manage custom fields for log filtering. |
| **Service Collection** | For each service, toggle the log collection and the file path.<br>**Note:**<br>Audit log collection is mandatory and cannot be disabled. |

7. Click **SAVE** to save your changes, or **RESET TO DEFAULT** to revert your changes.

# Overview of Log Standardization

By introducing a unified log standard, VCF enhances log usability, simplifies troubleshooting, and improves automation capabilities. The adoption of industry standards and structured logging ensures that logs are more consistent, easy to interpret, and valuable for your organization, your support teams, and your automation processes. The log standard introduced in VCF is a significant step toward greater observability, system efficiency, and proactive problem resolution.

### Why a New Log Standard?

Logging serves as a key source of information for system management, troubleshooting, and automation. Global support teams rely on log statements to diagnose issues, optimize performance, and enhance automation processes. In previous versions, VMware products such as vCenter, vSphere, Aria Operations for Networks, have followed their own logging

standards, often based on the RFC 5424 Syslog Protocol. Though functional, this approach introduced inconsistencies in log formats and patterns, making interpretation more complex and reducing the efficiency of automated log analysis.

To address these challenges, VCF introduces a standardized log format. This new format aligns with industry best practices, including OpenTelemetry principles. It is designed to improve log consistency across components, simplify troubleshooting, and facilitate automation-driven log consumption. In VMware Cloud Foundation 9.0, three components follow a unified format, offering greater interoperability. In future versions, more components will adopt the standardized log format. This reduces the complexity of integrating new tools or migrating to new VCF versions since updates will follow this standardized approach.

### Objectives of Log Standardization

VCF benefits from standardizing logs because of the following reasons:

- Unified Logging Standard: Establishing a single log statement standard across the VMware Cloud Foundation platform while incorporating industry standards.
- Enhanced Automation and Parsing: Enabling automated log parsing and interpretation to improve operational efficiency.
- Ease of Configuration: There is now a single place to enable or disable log collection as well as configure its granularity. The approach is applicable for cross-datacenter VCF platforms by utilizing log forwarder capability within the cloud proxy.

### Impact of Log Standardization on Existing Workflows and Automation

- Automation Adjustments: If you use automated workflows that are tied to logging data, then you may need to adjust your processes for the components using the new log standard. Since the standardized format introduces specific fields (for example, timestamps, user actions, and component details), any custom scripts or automation routines relying on previous formats will require updating to the new structure.
- Dashboard and Alert Configuration: If you have dashboards or alert definitions that are connected to log data, initial reconfiguration is necessary. You can combine log based symptoms with metric based symptoms, ensuring that crucial insights are not missed due to format discrepancies. You can build log based widgets with the existing VCF Operations dashboards. This functionality is new in VCF 9.0.

### Scope of Log Standardization

**Logs Within Scope**

The standardization effort covers log statements that are generated by VCF components that document system operations. This includes:

- Application Logs: These logs capture events, user interactions, errors, and warnings generated by VCF applications. An example is the vCenter logs stored at `/var/log/vmware`.
- System Syslog Transmissions: Standardized messages from network devices, servers, and applications, adhering to the syslog protocol. For instance,VCF Operations for networks logs syslog messages when a PAM session closes.
- Syslog Transmission of Audit Records: Many organizations collect and retain audit records for compliance and security. The new standard applies to transmitting these records via syslog but does not mandate or modify how VCF components store them internally.

**Logs Out of Scope**

Certain types of logs are excluded from standardization due to their unique characteristics and existing industry adherence:

- Transaction/Database Logs: These logs track changes within a database, such as SQL transactions, and are essential for data integrity and disaster recovery.
- Third-Party Logs: Logs generated by external software like Kafka, PostgreSQL, RabbitMQ, and Kubernetes, which already conform to independent standards.
- Network Logs: While network logs provide critical information about IP traffic, they are categorized under system logs and remain outside the current standardization effort.

## Using the Chart to Analyze Logs

The chart in the **Logs** page lets you perform visual analysis on the results of your query.

Charts represent graphical snapshots of the results of log search queries. The chart type can be changed and adjusted to represent the query in different ways, based on user preferences.

You can control the aggregation level of the chart. The **COUNT OF EVENTS** function is selected by default.

**Where you find the Logs Page**

Click **Operate** in the top navigation bar, and in the left navigation pane, click **Logs**. Select the **Logs** tab.

## Changing the Chart Display

You can change how charts look in the **Logs** page.

| Task | Procedure |
|---|---|
| Change the time range of a chart | In the **Logs** page, you can switch the period displayed in the chart. |
| Change the granularity of a chart | In the **Logs** page, you can switch between different time ranges for each point represented on the chart. The available ranges depend on the time range specified for the query. |

## Chart Types

Click **Operate** in the top navigation bar, and in the left navigation pane, click **Logs**. You can select different chart types to change the way the data is visualized. The options are available above the chart display.

Different chart types require different aggregation functions, the use of time series, and group-by fields.

| Chart Type | Aggregation Function | Time Series Requirement | Group-by Field Requirement |
|---|---|---|---|
| Column | Any | Time series | N/A |
| Line | Any | Time series | N/A |
| Area | Any | Time series | N/A |
| Bar | Any | Non-time series | At least one field |
| Pie | Count or Unique Count | Non-time series | At least one field |
| Bubble | Any | Non-time series | Two fields |
| Scalar | Any | Non-time series | N/A |
| Table | Any | Any | N/A |

### Aggregation Function

VCF Operations provides several aggregation functions.

**Change the Type**

You can change the aggregation and grouping of query results displayed in the chart to graphically analyze log events.

Verify that you are logged in to the VCF Operations web user interface with a role that has the relevant permissions. The number of drop-down menus that you see under the chart depends on the selected aggregation function.

1. Use the drop-down menus to the top-left of the chart to change the aggregation function and grouping type.
   - To view the number of events over time, select the **Time series** button.
   - To view only event values, select the **Non-time series** button and select at least one field.
2. Click **APPLY**.

**Table 1300: Change Aggregation and Grouping of Query Results**

| Type | Field | Description |
|---|---|---|
| Count of events | Events only | Creates a chart of the number of events for a specific query. |
| Unique count | Any field | Creates a chart of the number of unique values for a field. |
| Min | Numeric fields only | Creates a chart of the minimum value for a field. |
| Maximum | Numeric fields only | Creates a chart of the maximum value for a field. |
| Average | Numeric fields only | Creates a chart of the average value for a field. |
| Std dev | Numeric fields only | Creates a chart of the standard deviation for a field's values. |
| Sum | Numeric fields only | Creates a chart of the sum of values for a field. |
| Variance | Numeric fields only | Creates a chart of the variance for the values of a field. |

You can modify the way you view the query results.

| View | Description |
|---|---|
| To group query results by specific field values | From the drop-down menu in the chart, select **Non-time series** and a field under **Group By**. |
| To view the number of events for a field. | For example, the number of events per host, select select **Non-time series**, **Count of Events** and **Group By by hostname**. |
| To view a stacked bar chart for a field with groupings over time. | Select both the **Time series** check box and the field check box under **Group By**. |

## Aggregation and Grouping in the Chart

The following table contains examples to illustrate aggregation and grouping in charts.

**Table 1301: Example Aggregation and Grouping in the Chart**

| Selection in the First Drop-Down Menu | Selection in the Second Drop-Down Menu | Time series selection | Result |
|---|---|---|---|
| **Count of events** | **Time series** | **Time series** | The chart displays a bar chart with the number of events for the current query over time. |
| **Average** | **vmw_op_latency (VMware - vSphere)** | **Time series** | The chart displays a line chart with average value of operations latency over time. |

| Selection in the First Drop-Down Menu | Selection in the Second Drop-Down Menu | Time series selection | Result |
|---|---|---|---|
| **Count** | **vmw_esx_problem**<br>**Note:**<br>The vmw_esx_problem field does not appear by default. You must query the vmw_esx_problem field (Add Filter > vmw_esx_problem 'exists') so that vmw_esx_problem appears in the drop-down menu. | **Non-time series** | The chart displays a bar chart of the number of events for containing the vmw_esx_problem field. |
| **Count** | **Time series**, **vmw_esx_problem** | **Time series** | The chart displays a bar chart grouped by vmw_esx_problem over time. |

## Viewing Logs, Queries and Fields

In the **Logs** page, you can search for log messages in context, and collect and analyze log feeds from within VCF Operations. You can view log-related metrics for troubleshooting. You can also dynamically extract fields from log messages based on customized queries. For more information, see Log Fields.

### The Logs Page

After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Logs**. You can view logs, create queries, and fields. In the Logs tab of the **Logs** page, you can search and filter log events, and create queries to extract events based on timestamp, text, source, and fields in log events. Besides presenting the log stream, VCF Operations presents charts of the query results. You can save these charts to look them up later in the **Dashboards** page. You can access the **Logs** page if your user account is associated with a role that has the appropriate permission. You can view or edit settings in the **Logs** page, depending on the sub-categories and corresponding access levels selected for the permission.

#### Viewing the Logs for an Object

When VCF Operations is integrated with Log Management, you can view the logs for a selected supported object from the **Logs** tab in the inventory. You can troubleshoot a problem in your environment by correlating the information in the logs with the metrics.

### Where You Find the Logs Tab

After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Inventory**. Click the **Logs** tab. The **Logs** tab is available after you have configured Log Management in VCF Operations.

#### Log Queries

Queries in VCF Operations can retrieve and summarize events. Once created, you can compare queries.

You can create and save queries from the **Logs** page. To see saved queries click **Operate** in the top navigation bar, and in the left navigation pane, **Administration** > **Configurations**. Then, click the **Saved Queries** card. You can export query results, share your queries with other users, and can save, delete, rename, and load existing queries. You can take snapshots of queries and can save them to dashboards.

A query consists of one or more of the following:

| | |
|---|---|
| **Keywords** | Complete, or full-text, alphanumeric, hyphenated, and/or underscore matches. |
| **Globs** | Complete, or full-text, alphanumeric, hyphenated, and/or underscore matches. |
| **Regular expressions** | Sophisticated string pattern matching based on Java regular expressions. |
| **Field operations** | Keyword, regular expression, and pattern matches applied to extracted fields. |

| | |
|---|---|
| **Aggregations** | Functions that are applied to one or more subgroups of the results. |

VCF Operations supports the following types of queries:

- Message. A query made up of keywords, regular expressions and/or field operations.
- Regular expression or field. A query made up of keywords and/or regular expressions.
- Aggregation. A query made up of a function, one or more groupings, and any number of fields.

You can define custom alerts in VCF Operations and trigger them from scheduled queries of any type.

**Note:**

Some saved queries may contain expressions that cannot be converted into the VCF Operations UI-supported format. Attempting to interpret or partially render these queries may lead to incorrect behavior or confusion.

Some complex saved queries and log-based alert definitions may not appear in the UI due to parsing limitations. These items are skipped when their expressions cannot be converted into the VCF Operations UI-supported format. Saved queries do not save the aggregated query (chart view).

## Best Practices for Creating Search Queries

You can enter queries by using the search bar, or by entering filters.

Use the search bar to refine the results for events. While you can use a filter instead of the search bar, it is often easier to understand a query that uses the search bar over an equivalent filter. The best practice is to use the search bar instead of an equivalent filter when possible.

A filter allows you to create queries by using a regular expression, a field, Logical OR and AND operations, or a combination of search bar and filter queries.

When you create queries by using the search bar and filters, the following best practices apply:

- Ensure queries are not environment specific.
- When constructing a query, use keywords when possible, when keywords are not sufficient use globs, and when globs are not sufficient use regular expressions. Keyword queries are the least resource intensive type of query. Globs are a simplified version of regular expression and are the next least resource intensive type of query. Regular expressions are the most expensive type of query.
- Provide as many keywords as possible when using regular expressions or fields. If a regular expression includes a logical OR, for example `this|that`, do not include keywords. VCF Operations is optimized to perform keyword queries prior to regular expressions to minimize regular expression overhead.

### Log Fields

Fields are a powerful way to add structure to unstructured events and allow the manipulation of both the textual and visual representation of data. You can view the distribution of data for a specific field and access the fields library to view indexed and non-indexed fields. You can choose to index non-indexed fields for performance reasons.

Saved fields are available in the **Fields Library** card. To see the **Fields Library** card, click **Operate** in the top navigation bar, and in the left navigation pane, **Administration** > **Configurations**. You can export or import extracted fields from one VCF Operations instance to another.

## Using Fields in the Logs Page

Click **Operate** in the top navigation bar, and in the left navigation pane, click **Logs**. The Logs page displays a stream of log messages. You can extract any part of a log message that might be applicable to a query or aggregation by selecting the part of the message and clicking **Extract Field**. Fields are a type of regular expression query and are useful for complex pattern matching so you do not need to know, remember, or learn complicated regular expressions.

You can use Fields in different ways including aggregations and filters. Aggregations allow you to apply functions and groupings to fields. Filters allow you to perform operations over fields.

You can create new Fields by extracting them from the logs stream. After you select a part of the message and right-click, and then select **Extract Field**, you see the **Create Field** flyout section on the right side. Enter the values and click **SAVE** to create a Field.

| Field Context Value | Definition |
|---|---|
| Field Name | Only use alphanumeric characters. Ensure that all characters are lower case and use underscores instead of spaces as this makes fields easier to view. |
| Field Type | Select an option from the drop-down list. |
| Regex before value | Include as many keywords as possible. If this field is empty or only contains special characters, then the Regex after value must include keywords. |
| Regex after value | |
| Pre Context | Specifies the exact log text or pattern that immediately precedes the target value. While simple Regex is supported, it is highly recommended to use exact text strings to prevent partial query results.<br>Ensure a clear delimiter separates this context from the target value. Supported delimiters include spaces and the following characters: `` ` ~ ! @ # $ % ^ & * ( ) + = [ ] { } . `` |
| Post Context | Specifies the exact log text or pattern that immediately follows the target value. Like the Pre Context, prefer exact text over complex Regex to ensure accuracy.<br>Ensure a clear delimiter separates the target value from this context. Supported delimiters include spaces and the following characters: `` ` ~ ! @ # $ % ^ & * ( ) + = [ ] { } . `` |
| Keywords | Click **Additional Context** to add one or more keywords, which are separated by space, that appear within events containing the field. |
| Add Filter | A static field, operator, and a potential value that appears within events containing the field.<br>It is common to use this in conjunction with the VCF Operations agent and tags for events that do not contain keywords. |
| Available For | Select the users that can use this Field. |

## Extracted Fields and Regular Expression Handling

To ensure optimal performance and stability, the logs platform enforces strict handling of extracted fields. If an extracted field contains a complex or malformed regular expression (Regex) pattern, VCF Operations cannot process it. Instead, VCF Operations automatically drops the invalid field.

This strict validation applies to all extracted fields in your environment, including:

- Custom extracted fields that you create.
- Out-of-the-box extracted fields that are defined within installed Management Packs.

If you notice that specific extracted fields are missing from your log search results, or certain alerts that rely on extracted fields are failing to trigger, then VCF Operations may have dropped the extracted fields during processing because their underlying Regex patterns were too complex or malformed.

To verify if the logs platform dropped your extracted fields, review the system logs for specific warning messages. Look for log entries marked with a **WARNING** severity level that match the following format:

```
Unable to extract fields:["<field_name_1>", "<field_name_2>"]
```

## Field Governance in the Fields Library

Fields can be manually added from the endpoints sending the logs, such as a FluentD agent. When a log is ingested, Log Management discovers the field, but does not index it by default. Indexing a field makes it quickly searchable in the **Logs** page. Searching by a non-indexed field takes a long time, though it is still searchable. The rediscover option removes a field from the database. This is an option when you want to remove the indexing manually. You can decide which fields

are indexed, thus saving storage and index bloat. This helps maintain capacity limits to prevent performance degradation. If the field continuously appears in subsequent logs, it is discovered again as a non-indexed field.

A Field can be:

- Indexed or Non-Indexed
- System Defined or Discovered

| | |
|---|---|
| **System Defined and Indexed Fields** | • These are well-known fields that come when the Log Management component is installed, and is required for proper functioning. This includes Fields for diagnostics, findings, and audit trails.<br>• The system marks these Fields as indexed by default.<br>• Approximately 77 indexed Fields are included by default.<br>• System-defined Fields cannot be rediscovered. |
| **Discovered and Non-Indexed Fields** | • When a Field which is not predefined in the system is ingested from an agent, it is marked as non-indexed and discovered. |

You can manage Fields by clicking the vertical ellipsis next to a field in the **Fields Library**. To see the **Fields Library** card, click **Operate** in the top navigation bar, and in the left navigation pane, **Administration** > **Configurations**.

- Indexing a Discovered Field**:** You can choose to index a discovered field by clicking **Index Field.** You see a confirmation message stating that indexing a field can reduce storage size and affect performance.
- Rediscovering a Field**:** For discovered fields, you can choose to rediscover a field by clicking **Rediscover**. This action removes the field from the index. If the same field continues to be ingested, it will be rediscovered but will remain non-indexed. You can then choose whether to index it again.

## Best Practices for Fields

In addition to the various components that make up a field, several best practices apply.

- Only create fields for regular expression patterns. If a field can be queried using keyword queries, or will only ever return a single value, then use keyword queries instead of a pre-defined field. If a field will only return two values then consider constructing individual queries instead of extracting a field. Fields are meant to add structure to unstructured data as well as provide a way to query over specific parts of an event.
- Only create fields for regular expression patterns that return a fraction of the total events. Fields that will match most events and/or return a very large number of results are not a good candidate for field extraction. The regular expression will need to be applied to a large quantity of events resulting in a resource intensive operation. If possible add additional keywords to reduce the number of results returned and optimize the query.
- If a field contains keywords within regular expression syntax, then add such keywords as a filter without regular expression syntax. For example, if the value or the context of a field contains keywords within regular expression syntax such as `this|that`, then add the keywords as a text filter to optimize the query like `text contains this, that`.
- Use of the additional context with one or more keywords is recommended over complex regular expressions in the before or after context.
- Add additional context to all extracted fields in order to optimize query performance.
- Extracted fields must be specific because the extraction is executed only on the target logs. You must use ASCII characters in the name of extracted field.

### Searching and Filtering Log Events

Click **Operate** in the top navigation bar, and in the left navigation pane, click **Logs**. You can perform search and filter operations under **ANALYZE LOGS**.

> **Note:**
>
> The logic that is used in the filter preview is different from the logic that is used when filtering in the **Logs** page. For more information, see Log Management Filters.

## Performing a Search

To find only events that contain the specified keywords, enter any complete keywords, globs, or phrases in the search text box.

You can search for log events that match certain values of specific fields. Using quoted text in the main search field matches exact phrases. Entering a space in the main search field is a logical AND operator. Search uses only full tokens. For example, searching for "err" does not find "error" as a match.

> **Note:**
>
> The field name for an ingested event must begin only with a letter or an underscore character and contain only letters, digits, or the underscore character.

> **Note:**
>
> If searching for **esx** within a larger string, the query must be formatted as `esx` or `esx*` depending on the position of the sub-token.

Within a single-row filter, add multiple search queries by typing each query and hitting the Enter key. This behaves like OR filters. For example, select **hostnamecontains** and type `127.0.0.1` hit enter and then type `127.0.0.2` and hit enter again. The search returns events with the host name 127.0.0.1 or 127.0.0.2.

> **Note:**
>
> The **text contains** filter treats each word or phrase that you type before hitting enter as a complete keyword.
>
> Queries with fields using the internal query language syntax names, for example, `from` or `in`, are not able to be processed and should not be used.

You can combine multiple field filters by creating a filter row for each field. You can toggle the operator that is applied to multiple-row filters.

- To apply the AND operator, select **All**.
- To apply the OR operator, select **Any**.

> **Note:**
>
> Regardless of the toggle value, the operator for comma-separated values within a single filter row is OR.

You can use globs in search terms. For example, `vm*` or `vmw?re`.

- For 0 or more than two characters, use *.
- For only one character, use ?.

> **Note:**
>
> Globs can be used as the first character of a search term. For example, you can use *.10.11.12. However, using *10.11.12 does not work.

You can save the current query to load it at a later stage.

## Filter Log Events by Time Range

You can filter log events to view only the events for a certain period. You do that by selecting one of the predefined periods. To set the initial and final point of the time range, select **CUSTOM**.

Search Log Events by Field Operations
You can use the list of existing fields to search log events with specific values for the selected field.

Verify that you are logged in to the web user interface as a user associated with a role that has the relevant permissions. The relevant permissions are View and/or Manage for Logs.

> **Note:**
>
> VCF Operations indexes complete alphanumeric, hyphenated, and underscore characters.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Logs**.
2. Click **Add Filter**.
3. In the filter row under the search text box, use the first drop-down menu to select any field defined within VCF Operations .

   For example, **hostname**, **text**, **source**, and so on. To query logs from an existing index partition, select the partition from the **PARTITION** drop-down list on the top right. Selecting a partition lists a specific subset of events based on the partition filter and renders quick results.

   The list contains all defined fields that are available statically, in content packs, and in custom content.

   Fields are sorted by name, except for the **text** and **partition** fields. Because **text** is a special field that refers to the message text, **text** appears at the top of the list, and is selected by default. Because **partition** is also a special field that refers to index partitions, **partition** appears after the **text** field in the list.

   **Note:**

   Numeric fields contain additional operators that string fields do not: **=**, **>**, **<**, **>=**, **<=**.
4. In the filter row under the search text box, use the second drop-down menu to select the operation to apply to the field selected in the first drop-down menu.

   For example:

   - Select **is** or **is not**. These filters match the full name. Select the partition from the drop-down menu. Using **is** for a partition matches all the events stored in the specified index partition. Using **is not** for the partition matches all the events that are not stored in the specified index partition.
   - Select **contains**. The **contains** filter matches full tokens: searching for "err" will not find "error" as a match. Using **contains** for the partition matches glob patterns in all existing index partitions.
5. In the text box to the right of the filter drop-down menu, type the value that you want to use as a filter.

   You can list multiple values by hitting enter after typing each value. The operator between these values is `OR`.

   **Note:**

   The text box is not available if you select the **Exists** or **Does not Exist** operator in the second drop-down menu.
6. Optional: To add more filters, click **Add Filter**.

   **Note:**

   You can add only one filter when you select a partition. However, after adding a field and selecting a partition, you can add more filters using other fields.

   A toggle button appears with the All/Any option.
7. Optional: For multiple filter rows, select the operator between filters.

| Option | Description |
|---|---|
| **All** | Select to apply the `AND` operation between filter rows |
| **Any** | Select to apply the `OR` operation between filter rows |

   By default, **All** is selected.

   **Note:**

   The partition filter is considered as a supplemental field. The partition filter is combined with filters containing other fields using the AND operator. However, you can select the OR operator to combine filters with non partition fields.

8. Click **SAVE QUERY** and give a name and description.
9. Select the query from the **Choose Saved Query** drop-down list to run the query.

**Note:**

Querying will be slow if the field is not indexed. For more information on field governance, see Log Fields.

**Search for a Group of Hosts that Have a Common String in Their Names**

Assume that you have several hosts that have a host with the following name: w1-stvc-205-prod3, and another host that is called w1-stvc-206-prod5.

To find all logs for both hosts, create the following query.

1. Leave the search text box empty.
2. Define the query by performing steps 3 to 6.
3. Select **hostname** from the field drop-down menu.
4. Select **Starts With** from the operator drop-down menu.
5. Type in the value **w1-stvc** text box. Alternatively, you can use the contains operator, but then you must use a glob in the search value. In this example, you must type w1-stvc-* in the value text box.
6. Click **SAVE QUERY**. Give a name and description.
7. Select the saved query from the **Choose Saved Query** drop-down list.

Examples of Search Queries

Click **Operate** in the top navigation bar, and in the left navigation pane, click **Logs**. You can use these examples when building your queries.

**Note:**

VCF Operations indexes complete alphanumeric, hyphen, and underscore characters.

**Query for all heartbeat events reported by the ESX hostd process yesterday between 9-10am**

To query for all heartbeat events reported by the ESX hostd process:

1. In the search text box, type `heartbeat*`.
2. Define a filter.
   a. Select **appname** from the first drop-down menu.
   b. Select **contains** from the second drop-down menu.
   c. Type `hostd` in the value text box.
3. Define the time range.
   a. In the **Time Range** drop-down menu select **Custom**.
   b. In the first text box, enter yesterday's date and 9am.
   c. In the second text box, enter yesterday's date and 10am.
4. Save the query and run it.

**Search for a Group of Hosts that Have a Common String in Their Names**

Assume that you have several ESX hosts with similar hostnames, for example one with the following name: w1-stvc-205-prod3, and another with the following name: w1-stvc-206-prod5.

To find all logs for both ESX hosts, create the following query.

1. Leave the search text box empty.
2. Define the filter.
   a. Select **hostname** from the field drop-down menu.
   b. Select **starts with** from the operator drop-down menu.
   c. Type `w1-stvc` in the value text box.
   Alternatively, you can use the **contains** operator, but then you must use a glob in the search value. In this example, you must type `w1-stvc-*` in the value text box.
3. Save the query and run it.

**Query for all errors reported by vCenter tasks, events, and alarms**

To query for all errors reported by vCenter tasks, events, and alarms:

1. In the search text box, type `error`.
2. Define a filter.
   a. Select **vc_event_type** from the first drop-down menu.
   b. Select the **exists** operator from the second drop-down menu.
3. Save the query and run it.

Examples of Regular Expressions
You can type regular expressions in text boxes for field values to extract fields from log events.

The expressions that you type must use the Java regular expressions syntax.

**Table 1302: Additional Examples of Regular Expressions**

| Regular Expression | Description |
|---|---|
| [xyz] | x, y, or z |
| (info\|warn\|error) | info, warn, or error |
| [a-z] | A lowercase letter |
| [^a-z] | Not a lowercase letter |
| [a-z]+ | One or more lowercase letters |
| [a-z]* | Zero or more lowercase letters |
| [a-z]? | Zero or one lowercase letter |
| [a-z] {3} | Exactly three lowercase letters |
| [\d] | A digit |
| \d+$ | One or more digits followed by end of message |
| [0-5] | A number from 0 to 5 |
| \w | A word character (letter, digit, or underscore) |
| \s | White space |
| \S | Any character except white space |
| [a-zA-Z0-9]+ | One or more alphanumeric characters |
| ([a-z] {2,} [0-9] {3,5}) | Two or more letters followed by three to five numbers |

Compare Logs
While troubleshooting, you might have to analyze logs from multiple systems that interact with each other. For a specific time interval, you can run multiple queries with different query criteria to search for logs from various systems, and compare the logs. You can also compare logs that are based on the same query criteria but ingested at different times.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Logs**. Go to **COMPARE LOGS**.

   **Tip:**

   You can also compare logs from the **Analyze Logs** tab:

   - Do either of the following:
     – Enter a query and in the corner of the page, and click the compare icon. Add more queries to compare logs.
     – Enter a query and in the upper-right corner of the page, click the pin icon. Pin multiple queries to the pinboard and then click **Compare Logs**.
2. In the **COMPARE LOGS** tab, enter details for the first query.
   - Enter a name for the query.

- Select the indexed partition on which you want to run the query and click **Apply**. If you do not select an indexed partition, VCF Operations searches for logs in all the indexed partitions.
- Enter a start date and time for querying the logs. VCF Operations uses the start date and time and the duration in the upper-right corner of the page to calculate the time range for the query. When the query runs, it searches for logs within the time range.
- Add one or more filters for more specific query results.

3. Click **Add Query** to add another query and enter the details described in step 2. You can compare logs for up to four queries.

   **Tip:**
   You can copy an existing query by clicking the copy icon next to the query name.

4. In the bottom-right of the query section, enter the common duration for the added queries. VCF Operations uses the start date and time in a query and the common duration to calculate the time range for the query. When a query runs, it searches for logs within the time range.

   **Note:**
   You can enter a maximum duration of 29 days, 23 hours, and 59 minutes.

5. Click **Compare**.

The log comparison is displayed as a stacked line chart and the log results appear side by side in query tabs under the chart. You can select a query tab on the left side and a query tab on the right side to compare the log results.
By default, the chart is based on the logs corresponding to the selected query tabs. However, to view the chart for all the queries, in the upper-right corner of the chart, click **Show All**.

The chart is plotted based on the common time range for the queries. To view the specific time at which a log was ingested, you can hover over the data point in the chart.

**Information in Log Events**
VCF Operations collects and analyzes all types of machine-generated log data, including application logs, configuration files, messages, performance data, and system state dumps.

You can connect VCF Operations to everything in your environment, including operating systems, applications, storage, firewalls, network devices for enterprise-wide visibility using log analytics.

When VCF Operations is configured and ready to collect logs, there are several ways you can ingest log data including:

- vSphere Integration — VCF Operations can integrate with vSphere components to automatically collect events, tasks and alarms from vCenter and logs from ESX hosts.
- Agents — VCF Operations has collection agents available to send filelog, windows events and journald generated logs to VCF Operations.
- Syslog — VCF Operations can ingest data from any source via syslog. Just set the VCF Operations server as your syslog destination.
- CFAPI — Events are sent in their original format to VCF Operations using cfapi. Events sent over cfapi do not have to follow the guidelines of a syslog event and are not modified to comply with the syslog RFC.

Each event contains the following information.

| Type | Description |
|---|---|
| Timestamp | The time when the event occurred |
| Source | Where the event originated. This could be the originator of the syslog messages such as an ESX host or a forwarder such as a syslog aggregation. |
| Text | The raw text of the event. |
| Fields | A name-value pair extracted from the event. Fields are delivered to the server as static fields only when an agent uses the CFAPI protocol. |

**Note:**

VCF Operations is not responsible for the content of the log messages from the individual component. If you have a question about the log contents, contact the team that generated the log message.

Event Types Grouping
VCF Operations summarizes a large number of individual events into a smaller number of broad event types. VCF Operations uses machine learning to group similar events together, with each group showing the approximate number of events in the group. Grouping events helps identify the most communicative events and the most quiet ones, both of which are critical for troubleshooting.

The **Event Types** tab in the **Analyze** page, under the search bar, provides an aggregated view of the events for the given time range of the query. An event in a group is selected as the representative event. You can click the **Expand** link under each representative event to view the events in the group.As a result of grouping events, an Event Type is assigned to each event. An appropriate *event_type* field is created, which you can further use in regular queries. VCF Operations does not document the exact mechanism for grouping events. It tries to automatically detect groups of similar events based on the number of common parts that the events have. For example, let us consider the following events:

- `[2019-05-20 06:41:24.291+0000] ["SearchWorker-thread-12999"/10.113.164.150 INFO] [com.company.product.analytics.distributed.LogSearchWorkerService] [Worker fully completed query (token=5f6e5e1faf93e4ce) in 11 msec]`
- `[2019-05-20 06:41:24.284+0000] ["SearchWorker-thread-11961"/10.113.164.167 INFO] [com.company.product.analytics.distributed.SearchWorkerService] [Worker fully completed query (token=3b247b2ba6057c47) in 24 msec]`

These events have eight common parts - timestamp, thread name, host IP, logging level, class name, message text, token number, and duration. Now, let us consider the following events:

- `[2019-05-20 06:41:24.291+0000] ["LogSearchWorker-thread-12999"/10.113.164.150 INFO] [com.vmware.loginsight.analytics.distributed.LogSearchWorkerService] [Worker finished search (wait=59500 token=5f6e5e1faf93e4ce) in 12 msec]`
- `[2019-05-20 06:41:20.136+0000] ["AliasStudentStudyPool-thread-1"/192.168.110.24 INFO] [com.vmware.loginsight.analytics.alias.AliasStudent] [looking for alias due to rule DatastoreFromVmFileSystem]`

These events only have three common parts - timestamp, host IP, and logging level. In addition to grouping events together VCF Operations identifies useful fields in each event of the group, known as smart fields. Each smart field appears within the representative event as a hyperlink with a drop-down menu icon next to it. You can click the icon to view a histogram for the values of the field or to define an extracted field based on the smart field.

Analyze Event Trends
You can analyze log events for trends and anomalies.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Logs**.
2. Construct and run your query by using the search text box and applying filters.
3. Click the **Event Trends** tab.

   VCF Operations compares your query to the same time period immediately before and displays the results.
4. Select the period and sorting from the drop-down menus.

# Configuring Log Masking

You can add a configuration to mask sensitive information in all logs or logs that match the filter criteria you provide. You must provide the field or text to mask, the pattern for masking (entire or partial field), the mask value, and a filter criteria.

You can provide rules to mask sensitive information and preview the masking rule which highlights the part of the log that would be masked.

**Note:**

- A log mask configuration is applied only to the logs that are ingested after you create and activate the configuration.
- A log mask configuration can be created by providing **Field Name** and the filters selected from the static fields list.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Then click the **Log Processing** card.
2. Click the **Log Masking** tab.
3. The Log Masking tab displays existing filtering configurations in a list with the following key UI elements:

| Option | Description |
|---|---|
| **Name** | The log filter configuration name. |
| **Field Name** | The field that you have masked in the logs. |
| **Selector** | Regex selector for the field value. |
| **Mask value** | Value to replace the masked content of the specified fields. |
| **Status** | Shows if the log mask is activated or deactivated. |
| **Vertical Ellipses** | For the selected log mask, you can edit, clone, activate, deactivate or delete the log filter. |

4. Click **ADD**.
5. In the **Name** field, enter a unique name for the log mask configuration.
6. In the **Field Name** drop-down menu, select the field that you want to mask in the logs.
7. In the **Selector** text box, enter the regex selector for the field value, which indicates the part of the field that you want to mask. You must express this value as a capture group in the regex. Capture groups are identified with enclosed parentheses (). You can have multiple capture groups inside a selector. To mask all the content for a specified field, you can set the selector as `(.*)` or `(^[\s\S]$)`.
8. In the **Mask Value** text box, enter a value to replace the masked content of the specified fields, the default value for which is an empty string.
9. Select the **Enable Configuration** check box to enable log masking.
10. Click **Add Filter** to define the logs for which you want to mask information. If you do not add a filter, all the logs are masked. To see the results of your filter, click **PREVIEW**. Set filter conditions. You can add multiple filter conditions.

    **Note:**

    The logic that is used in the filter preview is different from the logic that is used when filtering in the **Logs** page. For more information, see Log Management Filters.

    - Contains
    - Does not contain
    - Starts with
    - Does not start with
    - Matches Regex
    - Exists
    - Does not exist
11. Click **PREVIEW** to preview the log mask or **CREATE** to save it.

The log masking configuration appears in the **Log Masking** tab. Any masking rule created via API may appear here. Click the chevron to see more information about the log mask. To modify a single row, click the vertical ellipsis next to the mask

you want to modify. For bulk activation, deactivation, or deletion, select multiple rows and click the horizontal ellipsis next to the add button.

## Configuring Log Filtering

Filtering log events allows you to control which log messages are ingested, forwarded, or dropped based on defined criteria. This capability enables focused logging, improves performance by reducing noise, and enhances security by excluding irrelevant or sensitive logs. This is useful when endpoints are unable to filter logs, allowing for the removal of unwanted data before indexing. Filtering at this stage still consumes resources from the log management Virtual IP (VIP), and this processing overhead should be factored into overall scale and performance considerations.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Then click the **Log Processing** card.
2. Click the **Log Filtering** tab.
3. The Log Filtering tab displays existing filtering configurations in a list with the following key UI elements:

| Option | Description |
|---|---|
| **Name** | The log filter configuration name. |
| **Status** | Shows if the log filter is activated or deactivated. |
| **Filters** | Filter the items in the table by name and activated or deactivated status. |
| **Vertical Ellipses** | For the selected log filter, you can edit, clone, activate, deactivate or delete the log filter. |
| **ADD** | Define new log filters. |

4. Click **ADD** to add a new filter. You can add up to a maximum of 10 filters.
5. Provide the following information:

| Option | Description |
|---|---|
| **Name** | Enter a unique name for the log filter configuration. |
| **Enable Configuration** | The log filter configuration is activated by default. To deactivate the configuration, click the **Enabled** toggle button. |

6. Click **ADD FILTER**. Set filter conditions. You can add multiple filter conditions.
   - Contains
   - Does not contain
   - Starts with
   - Does not start with
   - Matches Regex
   - Exists
   - Does not exist
7. Click **PREVIEW** to preview the filter or **CREATE** to save it.

   **Note:**

   The logic that is used in the filter preview is different from the logic that is used when filtering in the **Logs** page. For more information, see Log Management Filters.

The log filter configuration appears in the **Log Filtering** tab with information about the drop filter and whether it is activated. Click the chevron to see more information about the filter. To modify a single row, click the vertical ellipses. For bulk activation, deactivation, or deletion, select multiple rows and click the horizontal ellipses.

## Configuring External Storage

Configure NFS or S3 external storage locations for exporting logs, archiving logs, and importing archives. You must define a location before you can perform any of these operations. In the **External Storage** page, you can add, edit, and delete

locations and view their settings. Click the chevron against an entry to see more details. Click the vertical ellipsis to edit or delete an entry, or to import an external archive.

- Before you configure an NFS location as external storage, ensure that an NFS export is already set up and reachable from your VCF Operations deployment:
  - If you are using vSAN as the backing storage for your NFS export, see Enable vSAN File Service and Create a vSAN File Share to create an NFSv3 or NFSv4.1 export.
  - If you are using a third-party NAS or NFS server, set up the export according to your vendor's documentation.
- Before configuring an NFS share for import, export, or archive operations, ensure the target directory has the correct ownership and permissions and the path specified is relative to the mount point, and does not start with a leading "/".
- Before adding an NFS share or S3 location, ensure that all IPs in the VCF Management services Node pool are allowed by the NFS server or S3 endpoint, and by any firewalls between them, because log management traffic can originate from any of those IPs.
- To allow the system to write data successfully, the mounted NFS directory and its subdirectories require specific permissions. If the directory does not have the correct permissions, the log management service fails to start.
  - Ownership: The directory must be created by the root user.
  - Minimum Permission Level: 447 — read-only for Owner and Group, and read/write/execute for Others. This is the minimum permission level that VCF Operations requires to write log data successfully. You can also use a more permissive setting such as 777, but 447 is the minimum.

  If your NFS directory does not meet these requirements, update them using the following commands on your NFS server:

```
sudo -i
chmod -R 447 /path/to/your/directory
```

- Ensure that adequate free disk space is available in the external storage.

**Note:**

S3 is preferred to NFS for archive locations. Unlike S3, if an NFS filesystem is unavailable when the log management service is starting, the service will fail to start.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Click the **External Storage** card.
2. Click **Add New Storage**. You can add up to 5 external storage locations.
3. Under **Storage Type**, select either NFS or S3 from the drop-down list.
4. For S3, enter the following details:

| Option | Description |
|---|---|
| **Name** | The name to use for this external storage location. It is used to select the location from drop-down lists in Log Management. |
| **AccessKey** | The access key ID of the account or user that Log Management uses to connect to the S3 bucket. |
| **SecretKey** | The secret access key that goes with the access key ID. |
| **Bucket Name** | The name of the S3 bucket where the log data is stored. The bucket must already exist. |
| **Endpoint** | The URL of the S3 endpoint. The endpoint must use a certificate issued by a trusted Certificate Authority. Self-signed certificates are not supported. |
| **Server Side Encryption** | Specifies whether the S3 service encrypts the archived data at rest. |
| **Canned acl** | Determines the level of access granted to objects stored in your snapshot repository. The default is private, which means only the owner has full control. Change this setting only if your |

| Option | Description |
|---|---|
| | organization requires specific access permissions for shared or public access. |
| **Region** | The region of the bucket, in the format US_WEST_1. The S3 endpoint must use one of these AWS regions. |
| **Path Style Access** | Specifies whether to address the bucket in the URL path (`endpoint/bucket`) instead of in the host name (`bucket.endpoint`). Select this option if your S3-compatible storage doesn't support virtual-hosted-style addressing. |

**Note:**

You must use a certificate which is issued by a trusted Certificate Authority for S3. The self-signed certificate is not supported.

**Note:**

The S3 endpoint must support chunked transfer encoding, because Log Management uses it to upload data.

**Note:**

S3 is preferred to NFS for archive locations. Unlike S3, if an NFS filesystem is unavailable when the log management service is starting, the service will fail to start.

5. For NFS, enter the following details.
   - Host Name
   - Host Address. For example: `nfs://192.30.10.27:/mnt/logs`
6. Click **Validate** to test endpoint and credential validity.
7. Click **SAVE** to add new storage, or **Cancel** to abort.
8. After making changes, click **APPLY** to apply them. When you click Continue, the service is restarted and the changes are applied. Any other change you make also requires the service to be restarted.

   **Note:**

   Log Management is unavailable for up to a few minutes during the restart. During that time logs whcih are not stored by a Cloud Proxy with Data Persistence may be lost.

Troubleshooting

9. Follow these troubleshooting steps for Storage issues

**Table 1303: Troubleshooting NFS Storage Issues**

| Issue | Checklist for Troubleshooting |
|---|---|
| NFS Server Connectivity | Verify the NFS server is reachable |
| Export Path Validation | Ensure that the specified path exactly matches what is exported or shared by the NFS server. Do not specify a subfolder within the share. |
| NFS Unreachable Recovery | If an NFS server becomes unreachable and pods are stuck in ContainerCreating/Completed/Error state, perform a manual recovery procedure. |
| Write Permissions | Verify the NFS export path has write permissions for the user/group that the pods will use. |
| NFS Version Compatibility | Use `showmount -e <nfs-host>` to validate connectivity and export availability. This does not work with NFSv4. Verify NFS v3 or v2 is enabled. |

**Table 1304: Troubleshooting S3 Storage Issues**

| Issue | Checklist for Troubleshooting |
|---|---|
| Endpoint Format Validation | The endpoint must be a valid URI (starting with `http://` or `https://`), include a hostname, and optionally a port. Check for missing protocols or malformed URLs/hostnames. |
| Bucket Existence and Access | Confirm the S3 bucket exists and credentials are valid. Ensure the IAM user/role has minimum permissions: `s3:ListBucket` and `s3:HeadBucket`. |
| Write and Delete Permissions | Validation by creating and deleting a test object. If validation fails, verify the IAM policy includes `s3:PutObject` and `s3:DeleteObject` permissions for the bucket. |
| Canned ACL Configuration | Invalid Canned ACL values cause validation failure. Use the default private ACL if uncertain. |
| Region and Path-Style Access | Verify the region matches the S3 service region (AWS) or is appropriate for your S3-compatible service. For non-AWS S3, set `pathStyleAccess` to true if needed. |

# Log Import and Export

You can export logs to extract specific datasets resulting from an analysis or search query.

### Why Export Logs

- Data Extraction: You can search for specific logs within the Logs page and export the results for external use.
- Reporting: You can export event results and chart data, which is useful for offline reporting or external auditing.
- External Storage Archival: Up to 20K chart data logs can be exported to the local machine for long-term retention or backup. Event data can be exported to an external storage.

### External Storage Requirement

You can export logs to an external storage target, such as **NFS** or **S3**.

> **Note:**
>
> Imports operate at the index level, not at the individual log entry level. If an index's data range overlaps with the requested import interval even partially, the entire bucket is imported. As a result, some logs outside the requested interval may be included in the import.

## Exporting Logs and Chart Data

You can export log search results and chart data from VCF Operations for offline analysis, auditing, or archival purposes. You can initiate exports directly from the Analyze page and monitor the progress of these tasks from the Configurations menu.

To export datasets containing more than 20,000 results, you must configure an external storage path. Direct downloads to the local file system are limited to 20,000 results.

1. Click **Operate** in the top navigation bar, and in the left navigation pane, click **Logs**.
2. Use the search bar and filters to isolate the specific log events you want to export.
3. Go to the Stream tab below the chart.
4. Click the **EXPORT** button, and from the dropdown menu select **Chart Data** or **Events Results**.
5. If you selected **Events Results,** in the **Events Results** dialog box, configure the export settings:

| Option | Description |
|---|---|
| **Format** | Select JSON or CSV |

| Option | Description |
|---|---|
| **Task Name** | Enter a unique name to identify the export task. |
| **Select Storage Path** | Choose the destination for the export file:<br>• **Local:** Select this option for smaller datasets (up to 20,000 results) to download the file directly to your computer.<br>• **External Storage:** Select this option for larger datasets. You must specify the **Source** (Host S3 or NFS) and **Storage Path**. If no external storage is configured, click the **CREATE NEW** link. For more information, see Configuring External Storage.<br>Before configuring an NFS share for import, export, or archive operations, ensure the target directory has the correct ownership and permissions and the path specified is relative to the mount point, and does not start with a leading "/".<br>To allow the system to write data successfully, the mounted NFS directory and its subdirectories require specific permissions.<br>• Ownership: The directory must be created by the `root` user.<br>• Minimum Permission Level: `447` (Read/Write/Execute for Owner and Others).<br>If your NFS directory does not meet these requirements, update them using the following commands on your NFS server:<br>`sudo -i`<br>`chmod -R 447 /path/to/your/directory`<br>**Note:**<br>If no host is currently assigned, click the link provided in the dialog to assign a host or create a new configuration. |

6. If you selected **Chart Data**, select the desired file format. Options are CSV and JSON.
7. Click **EXPORT.**
8. A confirmation message appears stating the export task has been successfully added to the queue.

You can view the status of initiated export tasks to verify their completion.

1. Click **Operate** in the top navigation bar, and in the left navigation pane, click **Administration** and then **Control Panel**. Select the **Log Import/Export Tasks** card.
2. Review the task list. The table provides details including **Name**, **Owner**, **Storage Path**, **Export Format**, and current **Status**. You can cancel tasks which are in the queue.

## Archive Log Import

You can import logs from archived locations and search against these locations. This preserves old logs that might otherwise be removed from an index partition after the retention period. You can import archives from both the Aria Operations for Logs, and VCF Operations for Logs. To initiate an import task, it is mandatory to have external storage (NFS or S3) integrated.

### Before You Begin

Ensure that you have configured an external storage. For more information, see Configuring External Storage. You can import archive logs from the External Storage page as well.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Then click the **Log Processing** card.

2. Click the **Log Partitions** tab and then scroll to the bottom of the page to the **Imported Log Archives** section.
3. Click **INITIATE NEW LOG IMPORT**.
4. Enter the following details:

| Option | Description |
|---|---|
| Name | Specify a unique name for the import job. |
| Operation Type | From the drop-down list, select the type of import operation. Select **import** to import logs from log management. Select **legacy import** to import logs from Aria Operations for Logs. |
| Source | Specify that will execute the import. If no host is selected, configure the host first. Legacy Import supports only NFS storage. |
| Storage Path | Enter the full file system path (e.g., an NFS or SMB share) where the archive log files reside. This must be accessible from the assigned host, matching the file system convention used when logs were archived. |
| Collection Period | Specify the start and end dates (in **MM/DD/YYYY** format) covering the period of logs you wish to import. This narrows down the ingestion to logs within the given time frame |

5. Click **IMPORT LOGS**.

After the import task is completed, you can search against the restored data from the Logs page by selecting the **Import** section and the **archived logs** section in the drop-down menu. You can import only archive.

## Configuring Log Forwarding

You can configure a log management server to forward incoming log events to a syslog API target. A maximum of 10 forwarding rules can be created. You can forward logs to external services.

### Before You Begin

**Note:**

- Verify that the destination can handle the number of logs that are forwarded. If the destination cluster is much smaller than the forwarding instance, some logs might be dropped.
- Use log forwarding to send filtered or tagged logs to one or more remote destinations such as log management or syslog or both. Log forwarding can be used to support existing logging tools such as SIEM and to consolidate logging over different networks such as DMZ or WAN.
- Log forwarders can be standalone or clustered, but a log forwarder is a separate instance from the remote destination. Instances configured for log forwarding also store logs locally and can be used to query data.
- The network bandwidth, the destination availability, and performance and stability of the environment may impact the reliability of Log Forwarding feature.
- During the upgrade process, any existing log forwarder rules from the Aria Operations for Logs or VCF Operations for Logs are pulled and added into log management.
- Forwarding to Aria Operations for Logs 8.1x is supported.

### Configure Log Forwarding

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Then click the **Log Forwarding** card.
2. Click **ADD**.

3. Enter the following details:

| Option | Description |
|---|---|
| Name | A unique name for the new destination, Host, The IP address, or fully qualified domain name. |
| Enable Configuration | Enable or disable the log forwarding configuration. |
| Host | The IP address or fully qualified domain name.<br>**CAUTION:**<br>A forwarding loop is a configuration in which a Log Management cluster forwards logs to itself, or to another cluster, which then forwards the logs back to the original cluster. Such a loop might create an indefinite number of copies of each forwarded log.<br>When creating forwarding destinations, take care not to create indirect forwarding loops. |
| Protocol | When logs are forwarded using **Syslog**, the log's original source is lost and the receiver can record the message's source as the Log Management forwarder's IP address or hostname.<br>When logs are forwarded using **Raw**, the behavior is similar to syslog, but syslog RFC-compliance is not ensured. RAW forwards a log exactly the way it is received, without a custom syslog header added by Log Management. The RAW protocol is useful for third-party destinations, because they expect syslog events in their original form.<br>**Note:**<br>• The source field might have different values depending on the protocol selected on the Log Forwarder:<br>a. For syslog and RAW, the source is the Log Forwarder's Log Management instance IP address. |
| Use SSL to secure your connection | You can optionally secure the connection with SSL for the ingestion API or syslog. If the SSL certificate provided by the forwarding destination is untrusted, you can accept the certificate when you test or save this configuration.<br>All log forwarder configurations must use certificates that include a valid SAN in order to establish proper communication in SSL-enabled mode.<br>To verify your configuration, click **VALIDATE CONNECTION**. This sends test logs to the destination. |
| Custom Fields | Custom fields, also called tags, are user-defined key-value pairs that can be configured log forwarders to categorize and enrich incoming log messages with additional metadata for filtering and analysis purposes. |
| Forward Complementary fields | Complementary fields are additional log message fields beyond the core syslog headers (hostname, appname, procid, msgid) that are optionally forwarded in structured data elements when the this setting is enabled on a log forwarder. |
| Transport Protocol | Select a transport protocol for syslog. You can select UDP or TCP. |

4. To control which logs are forwarded, click **Add Filter**.
   - Contains
   - Does not contain
   - Starts with
   - Does not start with

- Matches Regex
- Exists
- Does not exist

Click **PREVIEW** to preview the log partition or **CREATE** to save it.

**Note:**

The logic that is used in the filter preview is different from the logic that is used when filtering in the **Logs** page. For more information, see Log Management Filters.

**Note:**

Log filtering takes precedence over log forwarding. If there are any filtering rules, the logs matching to that rules are not forwarded.

## Log Management Filters

The filter preview in the log processing pages, and the filters that you use in the **Logs** page do not have a one-to-one correspondence by name. However, you can select operators that produce similar results for both formats.

This difference is important when you use the **PREVIEW** option after you add filters in the following Log Processing pages and use **ADD FILTER** in the **ANALYZE LOGS** tab of the Logs page:

- **Log Masking**
- **Log Filtering**
- **Log Forwarding**
- **Log Partitions**

### Matching Logic Differences Between Log Filtering and Log Processing Filter Preview

When you compare log search using filters in the Logs page with filter preview in the log processing pages, you will observe differences in how search strings are matched. This behavioral difference occurs because Logs page search ues Query Domain Specific Language (DSL) which has a strict token-based matching, whereas log processing filters use flexible full-text matching.

| | |
|---|---|
| **Token-Based Matching (Query DSL)** | In Query DSL, most operators (with the exception of regular expressions) evaluate text at the token level. The system divides the log text into individual tokens separated by specific delimiters. The following characters act as token separators: `~ ! @ # $ % ^ & * ( ) + = [ ] { } \ \| ' : ; / ? , . < > " \t \n Space`<br><br>For a query to return a match in Query DSL, the search criteria must align perfectly with the defined token boundaries. |
| **Full-Text Matching (Log Processing)** | Unlike Query DSL, the DSL used in the log processing tabs (Log Masking, Log Filtering, Log Partition, and Log Forwarding) evaluates the full text string as a single entity rather than breaking it into tokens. This approach is more flexible and successfully matches partial words or substrings, even if they do not align with token boundaries. |

### Matching Behavior Examples

The following examples illustrate how the different matching engines evaluate the same log text and query.

- Target Log Text: `Filter Logic In|VCFOps`

- Generated Tokens: `Filter`, `Logic`, `In`, `VCFOps`

| UI Query | Query DSL Result (Logs page filter) | Log Processing filter | Reason |
|---|---|---|---|
| text contains `Logic In` | Match | Match | The query phrase exactly matches complete, individual tokens (`Logic` and `In`), and also exists as a substring in the full text. |
| text contains `Logic I` | No Match | Match | The letter `I` is a partial string and does not match the full token `In`. Therefore, Query DSL rejects it. However, the log processing engine detects `Logic I` as a valid substring within the full text. |

Because of this architectural difference, you might experience inconsistent behavior when testing preview in the log processing pages, and when using the logs filter in the Logs page, particularly when your search criteria includes partial words or substrings that do not align with standard token boundaries.

## Overview of Log Management Agents

A Log Management agent collects logs from log files and forwards them to a Log Management server or any third-party syslog destination.

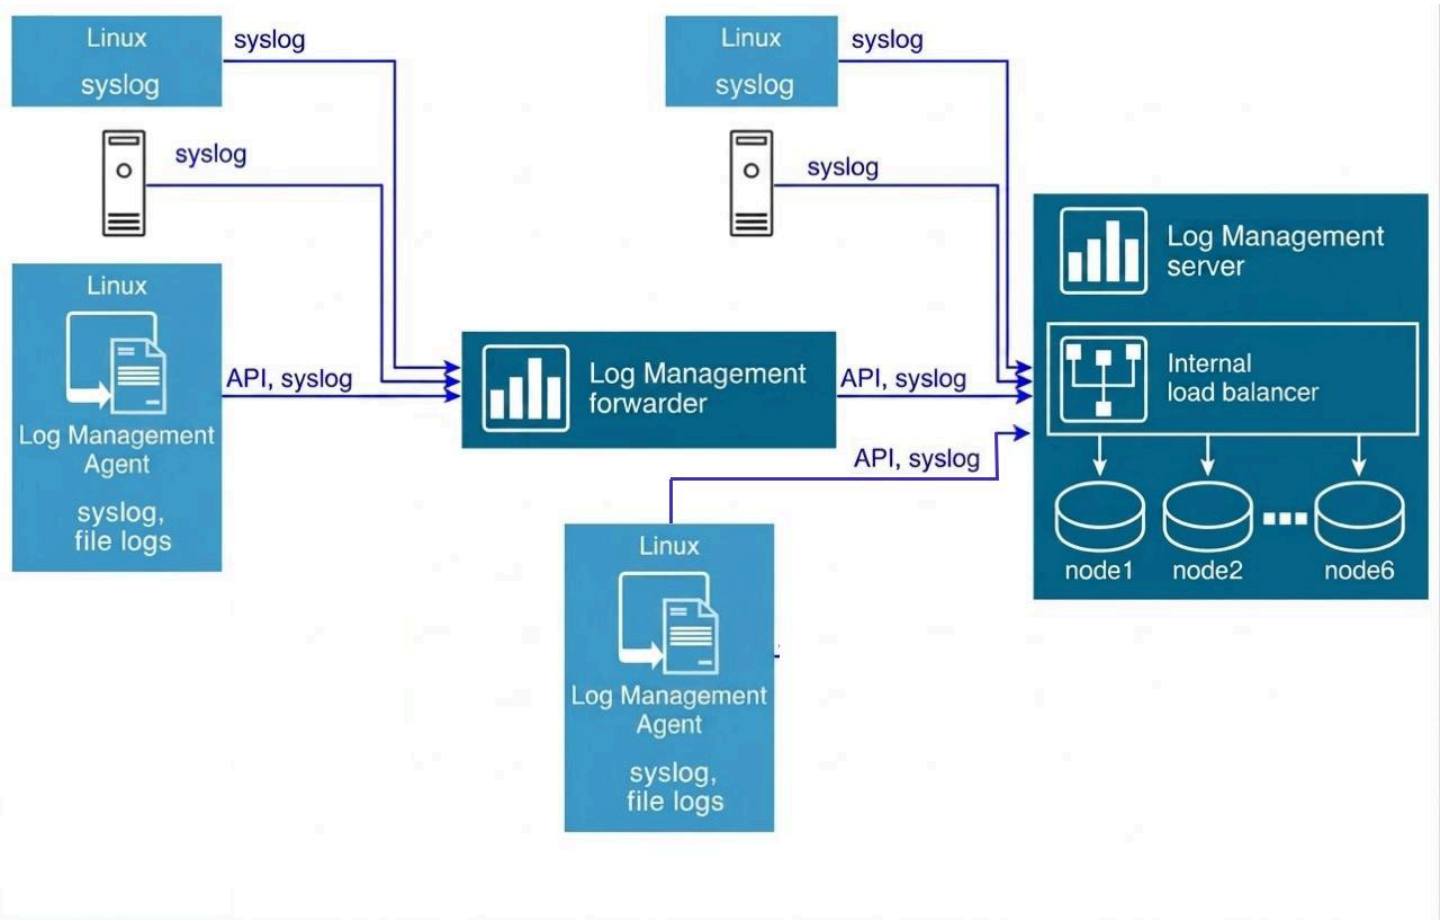
Agents support syslog and the Log Management ingestion API (cfapi protocol) and can be used with Linux. You configure agents through their web interface, through the liagent.ini file on the server and client side, or as part of installation.

Agents include the following features:

- Single or group deployment
- Automatic upgrade
- Parsing that operates on log messages and extracts structured data. You can configure parsers for FileLog and WinLog collectors or both.
- Support for multi-line messages
- Native support for several log rotation schemes
- An extensive ingestion API that includes client-side compression, encryption, and the ability to add metadata to logs

The Log Management server supports centralized configuration management and creation and management of groups of agents.

The following figure shows the elements of an agent deployment configuration.



A Log Management log forwarder is a dedicated instance of a Log Management server whose primary job is to forward logs to a remote destination. Normally, a server instance used as a forwarder is not used for query. The forwarder uses an internal load balancer and is otherwise structured like a Log Management server.

Agents write their own operation logs. For Linux, the path for the operation log is `/var/log/loginsight-agent/liagent_*.log`. Log files are rotated when an agent is restarted or when the file reaches a size of 10 MB. A combined limit of 50 MB of files is kept in rotation. You cannot collect agent logs with the Log Management agent itself.

Agents are used for real-time log collection. Use the Log Management importer to import historic log collections, including support bundles.

On Linux systems, the agent runs as a daemon and starts immediately after installation. The Log Management Linux agent collects logs from log files on Linux machines and forwards them to Log Management servers or syslog destinations. Debian, Red Hat, and Linux binary installation packages are available.

Use the following commands to install the Linux packages:

- For deb:`dpkg -i <deb_package>`
- For RPM: `rpm -i <rpm_package>`

In both cases, you must have appropriate permission to install the packages.

**System and Operating System Requirements**

Log Management Agents support installation on Linux operating systems that satisfy the following core system component dependencies:

- OpenSSL: Version 3.0 or higher
- systemd: Version 235 or higher

**Supported Operating System Versions**

| Operating System | Supported Versions |
|---|---|
| Red Hat Enterprise Linux (RHEL) | RHEL 9, RHEL 10 |
| SUSE Linux Enterprise Server (SLES) | SLES 15 SP7, SLES 16 |
| Ubuntu | Ubuntu 22.04 LTS, 24.04 LTS, 26.04 LTS |
| Debian | Debian 12, Debian 13 |
| VMware Photon OS | Photon 4.0 and higher |

## Configuring Agents

You can configure agents from within VCF Operations. Agents poll the Log Management component regularly to determine if new configurations are available. You can manage log collection agents to forward logs from vCenter instances and other components to VCF Operations. This includes downloading agent media, managing authentication secrets, monitoring agent status, and configuring agent groups.

For more information about secrets and agent authentication, see Agent Authentication for Log Ingestion.

**Note:**

Auto upgrade for the agents that are sending logs through Cloud Proxy Log Forwarder is not supported.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**.
2. Click the **Log Collection** tile and go to the **Agent** tab.
3. Click **DOWNLOAD AGENT**.
4. Download the agent.
   a) Navigate to the Broadcom support portal to download the Log Agent file. The supported formats are RPM and Debian.
   b) Import the file to your appliance and start the installation.
   c) Allow a few minutes for the system to detect the agent after deployment.

   Manage Agent Secrets

   Agents require a shared secret/token to authenticate with VCF Operations. You must generate this secret and copy it immediately, as it is displayed only once.
5. Select the **SECRETS** tab.
6. Click **GENERATE SECRET**.
7. In the **New Secret Creation** dialog, enter a **Secret name** (for example, `IP_FQDN_OF_Agent Appliance`).
8. Click **CREATE**.
9. The system displays a **Secret created successfully!** message. Click **COPY** to save the **Secret Value** immediately.
10. Click the confirmation dialog box to close it.
11. Navigate to the `/etc/liagent.ini` file in the appliance where you installed the agent. In the `server` section, under hostname, add `secret=COPIED_TOKEN` and save the configuration file.

    Revoke a Secret

12. In the **SECRETS** tab, locate the secret that you wish to remove.
13. Click **Revoke** next to the secret name.
14. A confirmation dialog appears. Review the warning indicating when the secret is permanently removed from the system.
15. Click **REVOKE** to confirm. The status updates to **Revoked**, and the revocation date will be displayed.

    Monitor Agent Status

    You can monitor the health and activity of your connected agents.
16. Navigate to the **Agents** tab.
17. After you download and install the agent on a virtual machine, the agents will appear in a centralized list. This list provides detailed information about the virtual machine, the agent, and its current status. Review the agent list, which provides the following details:

    **Note:**

    For VCF agents, agent configuration coming from log management is not applied.

- **IP Address**. IP address of the agent VM.
- **Hostname**. Hostmame of the agent VM.
- **Version**. Version of the agent installed.
- **OS**. OS of the agent VM.
- **Secret Name**. The secret is displayed here. You can revoke this by clicking the vertical ellipses against the row.
- **VCF Component**. All log collection components which contain embedded agent has VCF component =yes value. These agents are not configurable.
- **Last Active**: The time elapsed since the agent last communicated.
- **Events Sent**: Total number of events forwarded.
- **Events Sent/Sec**: Current throughput rate.
- **Events Dropped**. Events dropped by the agent.
- **Uptime**. Agent uptime.
- **Status**: Indicates if the agent is connected or disconnected

## Configuring Agent Group

An Agent Group allows you to apply configurations to a specific subset of agents. For example, you might group all Log Management. You can create a group of agents that are configured with the same parameters.

**Note:**

VCF log agents deployed on VCF components cannot be added to agent groups. If you need to send logs to an external log management solution, use the log forwarding mechanism instead. For more information, see Configuring Log Forwarding.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Then click the **Log Collection** tile.
2. Click the **Agent Group** tab.
3. Click **ADD**.
4. In the **Creation** step of the wizard, provide a unique **Name** and **Description** for the agent group.
5. Select **Auto update for all Agents** if you want to provide the same settings for all the agents. Enabling this allows automatic updates. When enabled, all the agents listed under the configuration can pull updates from the underlying log platform and apply them to their virtual machines.

   **Note:**

   There can be agents that do not belong to any agent group. For such agents, you must decide whether the agents should be auto-updated or not. This behavior is controlled by a global auto-update flag. The flag is a dynamic

configuration, defaults to false, and can be managed from the Agents page using the Auto Upgrade Agents Group toggle.

6. Specify one or more filters for the agent group. To create a filter, click **ADD FILTER** and specify a field name, an operator, and a value. Choose one of the following fields to filter on:
   - **IP address**
   - **Hostname**
   - **Version**
   - **OS**
7. Select an operator from the drop-down menu and specify a value.
   - Contains -
   - Does not Contain
   - Starts with
   - Does not Start with

   a) Multiple filters are treated as AND operands, and multiple values of the same filter are treated as OR operands. Filters can contain wildcards, such as * and ?. For example, you can select the OS filter contains and specify the value windows to identify all your Windows agents for configuration.
8. Use the **Preview** button to preview the Agents that match the filtering criteria.
9. Click **NEXT**.
10. In the Configuration step of the wizard, click the radio button against **Agent Configuration**.
    - New Agent Group
    - Select from Templates. You can add an agent group that was defined as part of a VCF Operations Management pack to your active groups and apply an agent configuration to the group.
11. Click **CONFIGURE** to specify the agent configuration values. Alternatively, select **Code View** to provide configuration in the form of code.

The agent configuration is applied within 5 minutes.

**Note:**

An agent can technically belong to multiple agent groups; however, in such cases, the applied configuration is non-deterministic. No guarantees are provided regarding which group's configuration will be used, so you must avoid adding agents to multiple groups.

## Set up the Windows system to collect logs in VCF Operations

You can install the supported version of Fluent Bit on a Windows Server 2022 and Windows Server 2025 instance to collect Windows Event Logs, including System, Security, and Application logs. Once configured, Fluent Bit forwards these logs to Log Management using nested JSON.

- Verify that you have an instance running Windows Server 2022 or Windows Server 2025 and possess administrative access to the target server.
- Ensure there is outbound network connectivity from the server to the Log Management VIP on TCP port 9543.
- Download the custom 64-bit supported version of Fluent Bit MSI installer from the VCF Solutions Catalog.
- Obtain the required Log Management CA certificate.

1. Install the Fluent Bit binary using the custom MSI installer. You can double-click the downloaded MSI file and follow the interactive wizard prompts, which installs the software to the following directory: `C:\Program Files\fluent-bit\`.

Alternatively, for automated deployments, open PowerShell and run the silent install command: `msiexec /i fluent-bit-4.2.3-win64.msi /quiet /norestart`.

2. Create a dedicated directory for Fluent Bit log output by running the `New-Item -ItemType Directory -Path "C:\Program Files\fluent-bit\logs" -Force` command in PowerShell.
3. Navigate to the configuration folder at `C:\Program Files\fluent-bit\conf\` and rename the default `fluent-bit.conf` file to `fluent-bit.conf.old` to create a backup.
4. Create a new `fluent-bit.conf` file to specifically target Windows Event Logs and the Log Management destination. Insert the following configuration, ensuring you update the placeholder values (`<PATH_TO_LOG_FILE>`, `<PATH_TO_OFFSET_DB_FILE>`, `<YOUR_CUSTOM_FIELD>`, `<YOUR_CUSTOM_VALUE>`, `<LOG_MANAGEMENT_FQDN>`, and `<PATH_TO_CA_CERTIFICATE>`) with your actual environment details:

```
Ini, TOML
[SERVICE]
    Flush 5
    Daemon Off
    Log_Level info
    Log_File <PATH_TO_LOG_FILE>

[INPUT]
    Name winevtlog
    Channels Application, System, Security
    Interval_Sec 1
    DB <PATH_TO_OFFSET_DB_FILE>

[FILTER]
    Name    modify
    Match   *
    Rename  Message text
    Add <YOUR_CUSTOM_FIELD> <YOUR_CUSTOM_VALUE>

[OUTPUT]
    Name http
    Match *
    Host <LOG_MANAGEMENT_FQDN>
    Port 9543
    URI /api/v2/events
    Format json
    Json_date_key timestamp
    Json_date_format epoch_ms
    Header Content-Type application/json
    tls On
    tls.verify On
    tls.ca_file <PATH_TO_CA_CERTIFICATE>
```

   **Note:**

   For testing purposes only, you can temporarily set `tls.verify Off` to disable certificate verification. Do not use this setting in a production environment.

5. Open PowerShell as an administrator and register Fluent Bit as a Windows Service so that it starts automatically after a system reboot. Run the following command:

```
New-Service fluent-bit -BinaryPathName '"C:\Program Files\fluent-bit\bin\fluent-bit.exe" -c "C:\Program
 Files\fluent-bit\conf\fluent-bit.conf"' -StartupType Automatic -Description "This service runs Fluent
 Bit, a log collector that enables real-time processing and delivery of log data to centralized logging
 systems."
```

6. Start the newly registered service and verify its running status by executing the `Start-Service fluent-bit` and `Get-Service fluent-bit` commands.

   ```
   Start-Service fluent-bit
   Get-Service fluent-bit
   ```

   Verify that the Status is `Running`.

7. Verify that your Windows Server can successfully communicate with the Log Management server. In PowerShell, run the `Test-NetConnection ComputerName "FQDN" -Port 9543` command (substituting your actual FQDN) and confirm that the expected result is `TcpTestSucceeded: True`.
8. After confirming network connectivity, log in to the VCF Operations UI and navigate to **Operate** > **Logs**. Add a filter for `hostname contains [Your-Server-Name]` and confirm that new logs appear from the `winevtlog` source.

Upgrade

9. Back up your live config (at a minimum, the `conf\fluent-bit.conf` or `conf\fluent-bit.yaml`, plus `parsers.conf / plugins.conf` if you use them).
10. If Fluent Bit runs as a Windows service, stop it first (`Stop-Service fluent-bit` in PowerShell, or `sc stop fluent-bit`, depending on how it was set up).
11. Run the new installer. In many environments, this replaces the binaries under the same install directory.
12. Restore config files from backup.
13. Start the service again and confirm the logs.

## Agent Authentication for Log Ingestion

Agent authentication secures the HTTP ingestion path for log data by introducing an optional authentication mechanism using secrets and tokens. This feature supports both the Log Management agent and 3rd-party agents such as Fluentd or FluentBit. By default, authentication is enabled but optional. The server accepts both authenticated and unauthenticated logs. However, you can enforce authentication globally, rejecting any log ingestion requests that do not possess a valid token.

### Why Agent Authentication

| | |
|---|---|
| **Enhanced Security** | Prevents unauthorized log injection into the logging infrastructure. |
| **Flexible Integration** | Works with native Log Management agents and standard 3rd-party log shippers. |
| **Granular Control** | Secrets can be managed, revoked, and tracked individually. |

### Prerequisites & Limitations

Before configuring authentication, ensure the following requirements are met:

- Agent Version**:** Log Management agent version 9.1 or higher is required.
- Protocol: Authentication applies only to HTTP/HTTPS ingestion APIs. Legacy Syslog ingestion remains unauthenticated.

> **Note:**
>
> Windows agents are not supported.

### Managing Secrets

Secrets serve as the initial credentials used to authenticate an agent. You must generate a secret before configuring the agent. You can generate a secret in VCF Operations, or using REST API. For large-scale or automated deployments, use the REST API. For information on how to generate a secret using VCF Operations, see Configuring Agents.

### Configuring the Native Log Management Agent

1. Locate the `liagent.ini` agent configuration file on the target machine.
2. Open the file and locate the `[server]` section.
3. Add the `secret` property with the secret value generated from the Agent configuration page:

```
[server]
hostname=log-server-address
proto=cfapi
secret=<your_generated_secret>
```

4. Save the file.

The agent automatically exchanges this secret for a token and handle renewal when the token expires.

### Configuring Third-party Agents

Third-party agents do not have a built-in mechanism to exchange secrets for tokens. This process must be performed manually or using an external script. Refer to the FluentBit or FluentD documentation for more information.

### Enforcing Authentication

By default, authentication is optional. Unauthenticated logs are accepted, but if an agent attempts to authenticate with an invalid key, it is rejected.

To enforce strict authentication and reject all unauthenticated traffic, enable the setting in the Global Settings. Once enabled, any ingestion request without a valid Bearer token is dropped. Ensure that all agents are correctly configured before enabling this setting. For more information, see List of Global Settings.

### Revoking the Secret

If a secret is compromised or an agent is decommissioned, you can revoke the secret to block access. Revoked secrets are retained in the list for approximately 7 days for audit purposes before being permanently deleted. During this time, the name cannot be reused.

## Log Statement Standardization Format

VMware Cloud Foundation comprises various components each of which issue log messages.

In VCF , the following components use the standard format for their application log messages:

- vCenter
- ESX
- NSX
- VCF Operations HCX
- VCF Operations for networks
- VCF Operations
- Identity Broker
- VCF Automation

This standard addresses a long-standing problem of VCF components using component-specific formats, in some cases, multiple formats for the same component. These different formats complicate troubleshooting due to such factors as using different time stamp formats and recording information in different parts of the log message. The different formats also make it more difficult to automatically parse log messages.

Standardizing the log message format addresses both problems. It will make it easier to manually troubleshoot problems using the log statements and process the log statements programmatically. This standard is based on the ESX log formats for application log files that was introduced in ESX 8.0. If automatic parsing of log messages was developed for the earlier versions of the above noted components, this parsing logic may need to be updated to correctly parse the log statements compliant with the standard.

Application log messages are written into files that are maintained by components on their local file systems. The log statement standard applies to log statements issued by software modules authored by the VCF division and not to third-party software modules such as Apache Tomcat. In 9.1, centralized log collection transmits only ESX logs via syslog and these logs are already standardized

## Log Statement Standard

The log statement standard is described below using Augmented Backus-Naur Form (ABNF) notation. The standard describes the format of an application log message. This section summarizes the key elements.

In the standard, an application log message comprises three parts that are separated by spaces and terminated by a newline. The line below lists the format.

```
HEADER <space> STRUCTURED-DATA <space> MSG
```

> **Note:**
>
> HEADER and STRUCTURED-DATA must be in every log statement while the MSG part may be omitted.

The following log message is an example of one that is compliant with the standard:

```
2025-06-05T05:21:29.840Z INFO api 25572 [ops@4413 threadId=”639”
threadName=”127.0.0.1-8010-exec-26”] Completed POST /diagnostics/findings
```

The list below maps this example back to the format of a log message:

- HEADER: `2025-06-05T05:21:29.840Z INFO api 25572`
- STRUCTURED-DATA: `[ops@4413 threadId=”639” threadName=”127.0.0.1-8010-exec-26"]`
- MSG: `Completed POST /diagnostics/findings`

This example illustrates three key principles of the log message format.

First, the first two parts of the log message format (HEADER and STRUCTURED-DATA) contain sub-parts separated by spaces. For example, the header includes four sub-parts (timestamp, severity, app-name (application name), and proc-id (process ID). The meaning and format of the sub-parts are defined in the table below using Augmented Backus-Naur Form (ABNF) notation.

Second, the timestamps comply to the format defined in the RFC 5424 standard and, in addition, always use UTC/GMT. In earlier VCF versions, the lack of a uniform timestamp made it difficult to manually or programmatically order log messages. The log standard addresses this problem by mandating that all timestamps be in this format.

Finally, every log message that is compliant with the standard includes the sub-part `<string>@4413` in the STRUCTURED-DATA part. In the above example, the string is `ops`. This string reports the component that issued the log statement. In the example above, the log message was issued by VCF Operations. It is abbreviated as `ops`. The formal name for this sub-part is SD-ID. Its format is defined in the table below. The standard requires all compliant log messages to contain the SD-ID. This fact can be used in automatic parsing of log messages. Log messages that include the SD-ID are compliant with the standard. Log messages that do not include SD-ID may be partially compliant or not at all compliant. Parsing logic that is written for the standard will correctly parse compliant messages and may not parse non compliant messages.

If automatic parsing of log messages was developed for the earlier versions of the above noted components, this parsing logic may need to be updated to correctly parse the log statements compliant with the standard. Follow this guidance for reviewing existing parsing logic:

- Review existing automation logic
- If the logic is parsing log statements from components other than the three listed in this section, no action is required.
- If the logic is parsing log statements from the components that are mentioned above, search the application log files of the component for examples of the log messages of interest. Generally, the MSG part of the log message did not change. So, start by searching for the message ignoring any timestamps or other parts of the original log line.
- Review the log message examples found in the previous step. If the message includes the SD-ID, review the parsing logic for any changes.

To create a parser that can programmatically process the VCF application log message format, use the ABNF notation given below. Parser generators can be used to generate a parser that understands the format. Finally, as already noted,

the standard is based on the ESX 8.0 standard. There are a few differences between these standards, which can be understood by comparing the VCF log ABNF to the ESX ABNF for log files that the `vmsyslogd` service manages. An existing parser that understands this ESX log format can be modified and applied for parsing log messages compliant to the standard.

### VCF Application Log Message Format

Application logs are written by a component to its local file system.

| Parameter | Value |
|---|---|
| **SP** | `ASCII space %x20` |
| **LOG-MSG** | `HEADER SP STRUCTURED-DATA [SP MSG] %0A` |
| **HEADER** | `TIMESTAMP SP SEVERITY SP APP-NAME SP PROC-IDENTIFIER` |
| **APP-NAME** | `1*48PRINTUSASCII` |
| **PROC-IDENTIFIER** | `NILVALUE / 1*DIGITS` |
| **TIMESTAMP** | `FULL-DATE "T" UTC-TIME`<br>Complies to RFC 5424 with the requirement for UTC/GMT formatting. |
| **FULL-DATE** | `DATE-FULLYEAR "-" DATE-MONTH "-" DATE-MDAY` |
| **DATE-FULLYEAR** | `4DIGIT` |
| **DATE-MONTH** | `2DIGIT ; 01-12` |
| **DATE-MDAY** | `2DIGIT ; 01-28, 01-29, 01-30, 01-31 based on month/year` |
| **UTC-TIME** | `TIME-HOUR ":" TIME-MINUTE ":" TIME-SECOND [TIME-SECFRAC] "Z"` |
| **TIME-HOUR** | `2DIGIT ; 00-23` |
| **TIME-MINUTE** | `2DIGIT ; 00-59` |
| **TIME-SECOND** | `2DIGIT ; 00-59` |
| **TIME-SECFRAC** | `"." 3*6DIGIT`<br>Providing fractional seconds is considered very important. Millisecond resolution is the minimum allowed (3 digits) when they are added. |
| **SEVERITY** | `[ LINE-MARKER ] SEVERITY-STRING` |
| **SEVERITY-STRING** | `"EMERGENCY" / "ALERT" / "CRITICAL" / "ERROR" / "WARNING" / "NOTICE" / "INFO" / "DEBUG"` |
| **LINE-MARKER** | `"-" \| "+"` |
| **NILVALUE** | `"-"` |
| **STRUCTURED-DATA** | `1*SD-ELEMENT` |
| **SD-ELEMENT** | `"[" SD-ID [*(SP SD-PARAM)] "]"` |
| **SD-PARAM** | `PARAM-NAME "=" %d34 PARAM-VALUE %d34` |
| **SD-ID** | `SD-COMP-ID "@4413"` |
| **SD-COMP-ID** | `1*27PRINTUSASCII` |
| **PARAM-NAME** | `1*32PRINTUSASCII ; characters '"', '\' and ']' MUST be escaped.` |
| **PARAM-VALUE** | `UTF-8-STRING; ; except '', SP, ']', %d34 (")` |
| **MSG** | `UTF-8-STRING` |

# Log Based Alerts

You can create alerts in VCF Operations for events triggered by log symptoms. You can create a query directly in the Log Symptom definition, or select a list of saved queries. Alerts are triggered when incoming logs match the defined alert criteria and contain log entries corresponding to the alert's configured object type.

For more information, see Create a Log Based Alert Definition.

# Integrated Load Balancer

Integrated Load Balancer allows you to manage the IP and DNS addresses of their log management deployment. You can add multiple Virtual IP (VIP) addresses and corresponding FQDNs. You can also configure dual-stack (IPv4/IPv6) deployments by including IPv6 addresses (AAAA records). You can attach up to 5 static fields to VIPs. Logs flowing or ingested through that VIP will have those fields attached, making them searchable via those fields.

To ensure full functionality of Virtual IPs (VIPs), updating the certificate to include all VIP and FQDN entries is required, before a VIP can be created. This is necessary not only to prevent SSL host verification issues but also to satisfy system validation during the addition of new entries.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Configurations**. Then click the **Log Collection** tile.
2. Click the Integrated Load Balancer tab.
3. You list a list of Virtual IPs, their FQDN, and configuration status.
4. To add a new virtual IP, click **CREATE NEW VIRTUAL IP**. Optionally, click the vertical ellipsis next to the existing virtual IP and click **Edit**.

   **Note:**

   You cannot edit the default Virtual IP and FQDN. However, you can add field values to tag the default virtual IP.
5. Provide or edit the following information.

   Note: While HTTP-based logs should use the FQDN, syslog messages can be sent directly to the Virtual IP address.

| Option | Description |
|---|---|
| **Virtual IP** | Provide the virtual IP address that will be used by the load balancer to accept log messages. |
| **FQDN** | Provide the FQDN (Fully Qualified Domain Name). |
| **Fields (Optional)** | Provide one more field names and values to tag logs received by this VIP. For (TCP) syslog-based ingestion field tagging is not supported. |

6. Click **CREATE**.

# Log Administration

Log Administration is facilitated by the data set capability, which defines restrictions on which logs a user can access. This involves applying a scope, which can be restricted to specific log data sets (example, logs containing "application name x"), to a user or user group. The roles include log pages and other aspects.

## Defining a Data Set

You can define a data set to provide users access to specific content.

1. After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Control Panel** under **Administration.** Go to **Access Control** and then to the **Scopes** tab. Click the **ADD** or **EDIT** button, and then scroll down to the **Assign Log Data Set** section.
2. Click **Add Filter**.
3. Use the first drop-down menu to select a field defined within VCF Operations, to filter on.

   For example, **hostname**.

   The list contains static fields only and excludes fields that are extracted, user shared, and fields created through event_type filters.
4. Use the second drop-down menu to select the operation to apply to the field selected in the first drop-down menu.

   For example, select **contains**. The **contains** filter matches full tokens: searching for the string `err` does not result in `error` as a match.
5. In the filter box to the right of the filter drop-down menu, enter the value that you want to use as a filter.

   You can use multiple values. The operator between these values is OR.

   **Note:**

   The box is not available if you select the **exists** or **does not exist** operator in the second drop-down menu.
6. Optional: To add more filters, click **Add Filter**.
7. Optional: To verify that the filter behavior is what you want, click **PREVIEW**, which opens a window to check the logs corresponding to filter.
8. Optional: Click **SAVE**.

## User Management and Role-Based Access Control

Role-based access control lets you manage users and the tasks that they can perform.

### What are Roles

Roles are sets of permissions required to perform particular tasks. VCF Operations has a set of predefined roles. Additionally, you can create custom roles as part of defining security policies, and grant the roles to users. To change the permissions and tasks associated with a custom role, you can update the role settings. The updated settings take effect for all users associated with the role.

- To allow a user to perform a task, you grant the role to the user.
- To prevent a user from performing a task, you revoke the role from the user.

Managing roles for each user is based on their user login account. You can assign multiple roles to a user, in which case the role permissions are merged.

Users who cannot view or access certain objects or cannot perform certain operations were not assigned the roles with the permissions to do so.

### Role-Based Access Control

In VCF 9.1, the log management functionality has been converged into the VCF Operations role based access control. As part of this integration, the legacy log-specific access controls have been migrated to the centralized VCF Operations roles.

This unification allows administrators to manage users, groups, roles, and scopes for both infrastructure monitoring and log management from a single control panel.

For more information, see Access Control in VCF Operations.

| | |
|---|---|
| **Users** | You can control the access and actions of each user by granting or revoking roles to or from the login account of the user. |

| | |
|---|---|
| **Permissions** | Specific permissions control access to log features. If a user's role lacks a specific permission, the corresponding feature tile, APIs, or page in the UI will not be visible to them. For example, tiles such as Log Processing, Log Forwarding, Log Collection, and External Storage are controlled by permissions.<br><br>You can manage permissions in the **Access Control** card by clicking **Operate** in the top navigation bar and in the left navigation pane, clicking **Administration** > **Control Panel**. Go to the **Roles** tab and edit a role to select or deselect the permissions appropriately. For more information, go to the topic, Add or Edit Roles and Assign Permissions. |
| **Data Sets** | Data sets consist of a set of filters. You can use data sets to provide users with access to specific content by associating a data set with scopes. The logs that the user sees in the Logs page, log based widgets and saved queries, is dependent on the data set assigned to them. |
| **Roles** | Roles determine what a user can do within the platform. A role is a collection of specific permissions (privileges).<br><br>• Built-in Roles**:** VCF Operations includes built-in roles, such as **Administrator** (full permissions) and **Read-only** (limited permissions).<br>• **Custom Roles:** Administrators can create custom roles by selecting a specific subset of permissions to tailor access for different user personas. |
| **Scopes** | Scopes determine what data a user can see. In VCF Operations 9.1, a Scope is a container that can include two distinct types of visibility configurations:<br><br>• **Object Scope:** Defines which infrastructure objects (example, Clusters, VMs) are visible to the user in the inventory.<br>• **Log Data Set:** Defines filters for the raw log data available to the user (example, Text contains 'error'). |

In VCF Operations 9.1, Object Scopes and Log Data Sets are independent. Selecting a set of objects (example, Cluster A) in the Object Scope does not automatically restrict log visibility to only logs coming from Cluster A.

- Log visibility is determined solely by the filters defined in the **Assign Log Data Set** section of the Scope.
- It is possible to assign a Log Data Set to a user without assigning an Object Scope. In this scenario, the user will see the filtered logs but may not see the related infrastructure resources in the inventory.

## Configuration Workflow

1. Define the Scope (Data Sets)
   a. Navigate to Access Control > Scopes.
   b. Create a new Scope or edit an existing one.
   c. Define Log Filters: Under the **Assign Log Data Set** section, add specific filters to define which logs belong to this scope.
   d. (Optional) Define Object Scope: Select the infrastructure objects (Clusters, VMs) relevant to this scope.

   For more information, see Defining a Data Set.
2. Define the Role (Permissions). Ensure the role assigned to the user has the necessary log-related privileges.
   a. Navigate to Access Control > Roles
   b. Select a built-in role or create a new custom role.
   c. Verify Log Permissions: Ensure permissions such as **Log Processing**, **Log Forwarding**, or **Log Collection** are checked if the user is required to manage those configurations.

   For more information, see, Add or Edit Roles and Assign Permissions.
3. Assign to User or Group
   a. Navigate to Access Control > User Accounts (or User Groups).
   b. Create a new user or select an existing one.
   c. Assign Role by selecting the role that you configured previously.
   d. Assign Scope by selecting the scope that you configured previously.

   When you log in to VCF Operations, from the navigation bar at the top and click **Operate** and in the left navigation pane click **Logs**. You will only see logs that match the criteria defined in the assigned Log Data Set in the Logs page. When you go to **Administration** > **Configurations**, or **Control Panel**, you will only see the tiles for which they have been assigned permissions.

# Converting Content Packs to Management Packs

The Log Content Pack to VCF Management Pack converter is a utility designed to address the change in content packaging following the introduction of Log Management in VCF Operations. This tool allows you to convert any third-party and custom content packs into Management Packs, ensuring they remain usable within VCF Operations, which only supports Management Packs.

### Purpose of the Tool

- Converting any third-party Content Pack into a VCF Operations compatible Management Pack.
- Converting any custom Content Pack created into a Management Pack.

### How to use the Tool

**Note:**

Ensure that you have Java Runtime Environment (JRE) 17 or higher installed on the machine where you intend to run the conversion tool. You can run the following command to verify the version of Jave that is installed on the machine:

```
java -version
```

**Converting the Content Pack**

1. Download the conversion utility, and the README file wich contains the instructions. The utility can be found in the **Drivers and Tools** tab here, after you log in to the support.broadcom.com portal.
2. Log in to the Aria Operations for Logs or VCF Operations for logs and export the content pack you intend convert and install in VCF Operations.
3. Extract the downloaded utility zip file, which contains the JAR file and the README text file.
4. Go to the command line and execute the command provided in the README file to convert the exported content pack into a management pack. A new folder containing the converted pack file is created.

**Post-Conversion**

1. You must enable the setting. `Unsigned Pack File Installation` in VCF Operations. This is to prevent the error message, `No signature found on pack file` which is displayed during installation. Log in to the VMware Cloud Foundation Operations Administration UI and activate the **Allow Unsigned PAK Installation** under Administrator Settings.
2. Log in to VCF Operations and in navigation bar at the top, click **Operate** and in the left navigation pane, click **Administration** > **Integrations**. Click the **Repository** tab.
3. Click **ADD** and then click **BROWSE** to add the newly created management pack file.
4. Install the pack file even if it is already installed and ignore signature checking.
5. Upload the PAK file.
6. Accept the EULA (End-User License Agreement).
7. Proceed with the installation, which will take some time to complete.

**Post-Installation**

1. Once the installation has completed, verify that the management pack is available under the **Repository** tab.
2. The management pack will be a content-only management pack, meaning it will not have any metrics and the source is content pack converter tool.
3. Under the content tab, you can see the dashboards, alerts, and symptom definitions that originated from the original content pack.

# Converting Custom Log Alerts to Management Packs

You can export custom, user-defined alerts from Aria Operations for Logs 8.18, execute the command-line conversion utility, and install the resulting Management Pack within VCF Operations 9.1. Executing this transition preserves legacy monitoring intelligence. To prevent unauthorized modification of platform monitoring files, the custom management pack installation requires administrative privileges and a temporary modification of the security posture of the VCF Operations cluster.

Ensure that the following prerequisites are met before you begin.

- You have the administrator credentials for Aria Operations for Logs 8.18. This is required to access and export custom configurations.
- You have the administrator credentials for the VCF Operations 9.1 Administrator UI. This is required to manage security profiles and install files. For more information, see Accessing Logs when the VCF Operations Console is Inaccessible.
- Java Runtime Environment (JRE) or Java Development Kit (JDK) installed on the local machine, and the permission to run Windows, macOS, or Linux command-line terminal.
- Active registration for the Broadcom Support Portal.

1. Log in to the legacy Aria Operations for Logs 8.18 instance using administrator credentials.
2. Navigate to the **Alerts** section and verify that all custom, user-defined alerts are configured and saved.
3. Click the **Content Pack** tab in the main navigation menu.
4. Select **My Content** from the left-hand pane. Click the **Settings** gear icon located next to **My Content** at the top of the screen.
5. Click **Export**.

   Complete the mandatory fields in the export window. Verify that the custom alerts are selected along with their associated extracted fields (such as the Namespace). Complete the export to download the Content Pack file to the local administrative workstation.
6. Log in to the Broadcom Support Portal and navigate to the **Drivers and Tools** tab, locate the log management section, and download the conversion utility that matches your Java version — `cp-to-mp-convertor-jar-with-dependencies-jdk17.jar` for Java 17 through 24, or `cp-to-mp-convertor-jar-with-dependencies-jdk25.jar` for Java 25 and later. Also, download the **README** file.
7. Open a command prompt or terminal on the administrative workstation containing the downloaded JAR file. Grant permissions to execute the downloaded archive by running one of the following commands:
   a) `chmod +x cp-to-mp-convertor-jar-with-dependencies-jdk17.jar`
   b) `chmod +x cp-to-mp-convertor-jar-with-dependencies-jdk25.jar`
8. Execute the conversion command using Java to generate a .pak file. The examples below use the Java 17 build; substitute cp-to-mp-convertor-jar-with-dependencies-jdk25.jar if you downloaded the Java 25 build. Choose the syntax option that aligns with your migration goals:
   a) Option A: Single Content Pack Conversion. Run this command to convert a specific Content Pack file:

   ```
   java -jar cp-to-mp-convertor-jar-with-dependencies-jdk17.jar -i <path-to-content-pack-file> -o <output-directory>

   The utility creates a new output directory matching the name of the source Content Pack and generates a corresponding .pak file within it.
   ```

   a) Option B: Bulk Content Pack Conversion. Run this command to convert all files within a directory simultaneously:

   ```
   java -jar cp-to-mp-convertor-jar-with-dependencies-jdk17.jar -f <directory-containing-several-content-packs> -o <output-directory>

   The utility processes all Content Packs in the source folder and generates individual output directories for each generated .pak file.
   ```

9. Open a web browser and navigate to the VCF Operations Administrator UI by typing: `https://<VCF-OPS-FQDN>/admin`. Replace `<VCF-OPS-FQDN>` with the correct value and use the local administrator credentials.
10. Navigate to **Administrator Settings** and click **Security Settings**. Click **ENABLE UNSIGNED PAK INSTALLATION** to permit the deployment of custom, unsigned management packs.
11. Navigate to the **Software Install** workspace. Click **Install Software Update**.
12. Upload the custom `.pak` file that you generated. Check the box labeled **Ignore the PAK File Signature Checking** and follow the remaining on-screen prompts to complete the installation wizard.
13. Open a web browser, navigate to the VCF Operations UI, and log in with standard operating credentials. Navigate to **Operate** > **Configuration** > **Alert Definitions**.
14. Search for and verify that the converted custom alerts from Aria Operations for Logs 8.18 are listed and active.

# Log Management Health Overview Dashboard

The Log Management Health Overview dashboard is available to assist you in determining the appropriate course of action when a system alert is triggered. The Log Management Health Overview dashboard is used as a secondary function to assess the overall operation of the system when no alarms are present. The primary intent for this dashboard is to provide additional insights when an alert is raised, helping you understand the underlying condition that triggered the alert.

### Where You Find the Dashboard

After you log in to VCF Operations, from the navigation bar at the top, click **Operate** and in the left navigation pane, click **Dashboards** > **All** and in the **VCF Operations** group, select the **Log Management Health Overview** dashboard.

### Dashboard Structure

The dashboard is structured around four main categories that correspond to four alerts related to logs. The dashboard has a separate section for each of these four key aspects of the system.

| | |
|---|---|
| **Ingestion** | This relates to the process of logs being published to the gateway, sent to the log processor, and then to the log store. |
| **Retention** | This covers the log store indexing the data and then storing it on a disk. |
| **Availability** | This category covers any conditions that could cause the log service to become unavailable. |
| **Operation** | This focuses on asynchronous operations, specifically archiving (writing logs to external storage) and forwarding (configuring the system to send logs to another endpoint). |

### How to Use the Dashboard

The recommended flow for troubleshooting an alert is as follows:

1. Identify the Alert: The dashboard summarizes the number of critical and warning alerts and lists the triggered alerts.
2. Review Symptoms: Multiple conditions can be grouped under a single alert (for example, an ingestion problem). Click on the alert to view the specific symptoms that have been triggered (for example, "ingest queue capacity is greater than 10%" or "dropped events exceed 5%").
3. Find Remediation Steps: Return to the main dashboard and open the corresponding section (for example, the "Ingestion" section for an ingestion alert). This section describes each condition and provides remediation steps for diagnosis.
4. Review Data and Guidance: Within the relevant section, for each condition, data is presented to illustrate the current and recent behavior.
   a. Dial: Shows the current behavior.
   b. Chart: Shows the historical behavior.
5. Read the guidance provided in the text and follow the suggested steps, which may include reviewing other alerts (for example, checking the Availability alert if an ingestion queue capacity issue is observed).
6. Check Knowledge Base (KB): If the suggested remediation actions do not seem to apply, review the Knowledge Base article that is linked or mentioned.

The dashboard can be used to assess the overall operation of the system even when no alarms are present. In a healthy state, you would expect to see no red indicators. By reviewing the widgets, a user can gain comfort that the system is operating as expected.

The dashboard provides information such as:

- The current ingestion rate.
- The response time of the network.
- The status of retention problems.
- Confirmation that services and pods are up and running, and the log store health is green.

**Advanced Troubleshooting**

For advanced troubleshooting, there is a drill down dashboard that can be activated. The drill down dashboard is disabled by default. To activate it, go to Manage, search for *log*,and enable the disabled dashboard. This dashboard is laid out in the same style as the Log Management Health Overview dashboard, but it allows access to metrics about each individual component of the solution.

The log system architecture has three primary components: the gateway, the log processor, and the log store. The drill down dashboard is structured around these components (referred to as ingestion and retention services). Users can click on a component, see the listed instances, and then view the related metrics for a specific instance.

| | |
|---|---|
| **VCF management services Cluster Health** | If troubleshooting based on the logs dashboard suggests the VCF management services VMs may be overloaded, you can review the separate companion dashboard for the VCF management services itself. This page is an overview of the health of the VCF management services and the services running on it. |
| **Information** | This dashboard presents utilization metrics and a table listing the availability and memory usage of all services in the VCF management services cluster, including ops logs. It also details storage usage, backup, gateway information, and node details. |

You should start with the application health perspective (the logs dashboard) and then drill down to lower layers of the system, such as the VCF management services health page, to investigate potential issues like overloaded VCF management services VMs. For example, if CPU utilization is high but all applications are behaving well, it does not necessarily indicate a problem.

## Accessing Logs when the VCF Operations Console is Inaccessible

Log Management is integrated as a built-in, containerized core service running natively within the VCF Management Services Platform (VMSP). The VCF Operations console serves as the primary administrative interface for searching logs, running queries, analyzing trends, and configuring forwarding destinations. If the primary VCF Operations console is offline, unreachable, or undergoing maintenance, you can access local logs directly using the standalone Log Management emergency UI.

- The standalone Log Management FQDN or IP address that is configured during deployment is known and reachable.
- The local system administrator password that is created during VMSP runtime deployment is retrieved.

> **Note:**
>
> The standalone emergency interface uses the local **admin@vsp.local** system-level account. Bypassing the VCF Operations identity broker must be restricted to emergency troubleshooting and avoided in standard production workflows.

1. Open a web browser and navigate to the standalone Log Management FQDN: `https://<Log-Management-FQDN>`
2. At the login screen loads, enter the following administrative credentials:
   a) Username: `admin@vsp.local`
   b) **Password**: The password that is assigned to the **vmware-system-user** during VMSP platform deployment.
3. After you sign in, you can see the standalone interface, where you can click the **Analyze Logs** tab to perform direct diagnostic searches and verify platform status.

# Network Operations

Network Inventory provides you with an overview of your VCF Operations network resources and quick access to the VCF Operations for networks console.

You can access the **Network Inventory** page from VCF Operations by navigating to **Operate** > **Overview** > **Network**. The page includes several useful widgets that provide information on your deployments networking status and resources.

> **Note:**
>
> The scope of information that is provided in**Network Inventory** is limited to inventory, alert, and NSX health information if you have not deployed the VCF Operations for networks appliance. To deploy the appliance, click **Install VCF Operations for Networks** on the top right of the page. For more information, see Deploying VCF Operations for networks. For information on upgrading the VCF Operations for networks, see Upgrading Management Components.

| Widget | Description |
|---|---|
| Networking Inventory | Includes the networking objects in your inventory such as NSX instances, transport nodes, edge clusters, and others. You can use the provided links to navigate to the objects.<br><br>**Note:**<br><br>The count of NSX instances that are shown on the NSX inventory includes both NSX Adapter instances under NSX and VMware Cloud Foundation accounts. |
| Network Alerts | Includes a metric overview of the alerts in your environment. |
| NSX Managers and VPCs | Includes information on the NSX Managers and, if applicable, the Virtual Private Clouds (VPCs) associated with them. For more information on NSX Projects and VPCs, go to NSX Projects and VPCs. |
| NSX Health | Includes information any NSX Managers, transport nodes, or edge nodes experiencing issues. |
| Business Applications with Flows | Includes information that is sourced from VCF Operations for networks used for flow analysis your applications. By selecting the links included in the widget, you navigate to VCF Operations for networks where you can provided flow data to analyze and troubleshoot your applications. For more information on application discovery based on flows, go to Working with Application Discovery. |
| Traffic Summary | Includes an overview of the flow traffic in your environment for the last 24 hours. |

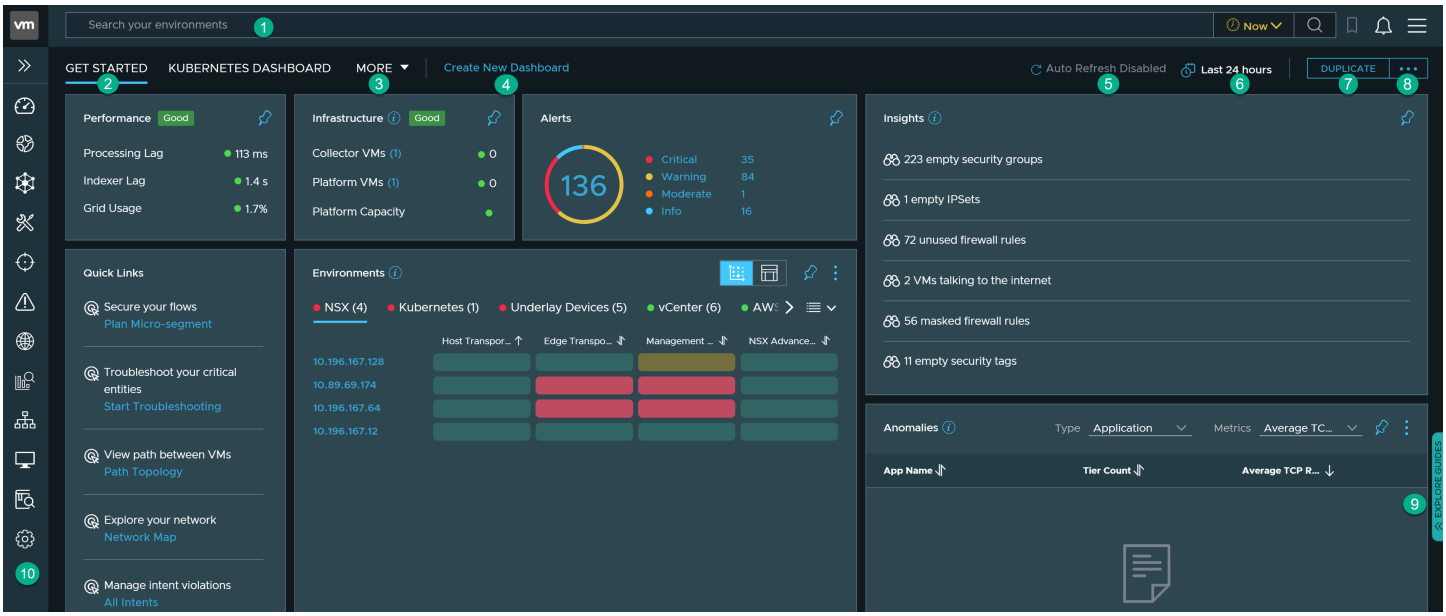
## About VCF Operations for networks

VCF Operations for networks delivers intelligent operations for software-defined networking and security. It helps customers build an optimized, highly-available, and secure network infrastructure across multi-cloud environments.

VCF Operations for networks accelerates micro-segmentation planning and deployment, enables visibility across virtual and physical networks, and provides operational views to manage and scale the VMware NSX deployments.

# VCF Operations for networks Homepage

The homepage enables you to create, view, and manage dashboards in VCF Operations for networks.



The homepage contains several elements:

| Elements | Description |
|---|---|
| Search bar (1) | Enables you to search across your entire data center network and its corresponding entities. Based on your requirement, you can perform search as per the following time line options:<br>• **Presets**: Using this option, you can narrow down your search results for presets such as last week, last 3 days, and last 24 hours.<br>• **At**: Using this option, you can narrow down your search results for a particular date and time.<br>• **Custom**: Using this option, you can search for data between a particular time interval. |
| Get Started (2) | Provides a high-level overview of your entire data center. The **Get Started** dashboard is available by default on the VCF Operations for networks homepage. |
| More (3) | If you have more than one dashboard, the **More** drop-down menu is displayed. This drop-down menu enables you to manage dashboards and arrange the order in which the dashboards are displayed on the homepage.<br>**Note:**<br>You can display a minimum of one dashboard and a maximum of five dashboards on the homepage. |
| Create New Dashboard (4) | Enables you to create a new dashboard and access it from the homepage. |
| Auto Refresh (5) | Enables you to change the auto refresh time frame at a global level. |

| Elements | Description |
|---|---|
| Last 24 hours (6) | Displays the dashboard data for the last 24 hours from the current time. Based on your requirement, you can view the dashboard data as per the following time line options:<br>• **Presets**: View the dashboard data for the last week, last 3 days, and last 24 hours.<br>• **At**: View the dashboard data at a particular date and time.<br>• **Custom**: View the dashboard data between a particular time interval. |
| Duplicate (7) | Enables you to duplicate the selected dashboard.<br>**Note:**<br>You cannot duplicate dashboards such as Kubernetes. |
| More options (8) | Enables you to edit, share, delete, and download the selected dashboard as PDF.<br>**Note:**<br>The options differ based on the dashboard you are accessing. For example, you cannot share or delete the **Get Started** and Kubernetes dashboards. |
| Explore Guides (9) | Shows guided workflows to perform some of the most important tasks in VCF Operations for networks. |
| Navigation pane (10) | Enables you to access key product features such as **Plan & Assess**, **Intent**, and **Entities** without having to type a search query. |

## The Get Started Dashboard

The **Get Started** dashboard is a system-defined dashboard that provides a high-level overview of what is happening in your entire data center. It also provides quick access to the important components of your data center.

The dashboard contains several widgets such as:

| Widgets | Description |
|---|---|
| Performance | Indicates the health of platform VMs, collector VMs, and the platform capacity.<br>**Note:**<br>If metric usage exceeds platform capacity, you will receive an alert with a recommended resolution to increase capacity. |
| Infrastructure | Displays the platform capacity. |
| Alerts | Displays the alerts sorted by the severity. |
| Insights | Highlights critical or behavioral changes in the network at the current time. This section also highlights entities such as applications, firewall rules, and VMs that need immediate attention. |
| Quick Links | Shows useful quick links. |
| Environments | Shows a heat map view indicating the health of entities associated with each environment type. |
| Anomalies | Shows error metrics for applications, VMs, and VMware NSX-T Edge Transport nodes. |

**Note:**
You cannot share, edit, or delete the **Get Started** dashboard. However, you can duplicate the dashboard and save the dashboard as a PDF file.

### VCF Operations for networks Security Compliance

VCF Operations for networks is a pre-hardened and secured appliance. VCF Operations for networks is hardened against well-established and industry-accepted security benchmarks, for example: CIS. Additionally, VMware security team has put internal controls to minimize the security footprint.

VCF Operations for networks also follows all security and privacy best practices defined by VMware Security Engineering, Communications, and Response (vSECR) team.

For any critical known vulnerabilities that require immediate action, VMware releases security advisories for those vulnerabilities with step-by-step instructions on how to keep the appliance secure. In general, all known vulnerabilities are fixed in every release. Use the latest version of the appliance to take advantage of these security fixes.

## Working with Data Sources

VCF Operations for networks allows you to add various data sources to gather information about your data center.

### Adding a Data Source in VCF Operations for networks

You must add data sources into VCF Operations for networks to gather data of your data center.

To add a data source, go to **Settings** > **Accounts and Data Sources** > **Add Source**.

After adding a data source, you see the **Accounts and Data Sources** page where data sources are categorized based on the following options:

- All: Displays all the available data sources.
- With Problems: Displays the data sources where VCF Operations for networks has found one or more problems.
- With Recommendations: Displays auto generated recommendations from VCF Operations for networks for the data sources that require additional information.

Each data source displays the following details

| Properties | Description |
|---|---|
| Type | Displays the type of data source. |
| Name | Displays the name of the data source. |
| Identifier | Displays IP address or FQDN details of data source. |
| Last Metric Collection | Displays the time stamp of the last metric data collection. |
| Last Configuration Collection | Displays the time stamp of the last configuration data collection. |
| Local Tags | Displays all the Working with Local Tags associated with the data source. |
| Polling Interval | Displays the polling interval that is defined for the data source. |
| Discovered Entities | Displays the number of VMs that are discovered for that data source.<br>**Note:**<br>The Discovered Entities column is populated only if the data source is VMware vCenter or AWS. |
| Flows | Displays the count of flows for the data source. |
| Data Collection | Indicates if the date collection on the data source is enabled or not. |

**Important:**
While adding a data source, do not add the same data source more than once using different IP addresses or FQDNs.

To select the columns that you want to view in the table, you can click the **Manage Table Columns** icon on the table header. You can view the details of maximum five columns at a time.

To edit or delete a data source, you can click the **More Options** icon next to the data source. For the data sources that support customizable polling interval, you can also use the **Collect Now** option to run the configuration data collection process.

VCF Operations for networks provides the following functions to enable easy access to the information of data sources.

- You can search a data source by name, IP address, or by the collector VM name by using the search bar located above the column headers.
- You can filter information by different data sources in the **Type** column. You can also filter data sources based on data collection in the **Data Collection** column.
- You can sort information by clicking the **sort** icon on any column.

VCF Operations for networks enables you to add different types of VMware products and other third party data sources ranging from public cloud, containers, firewalls, routers and switches, and load balancers.

## Supported Products and Versions

VCF Operations for networks supports several VMware and third party products and their different versions.

For the list of all VMware products and its supported versions in VCF Operations for networks, see the VMware Product Interoperability Matrix.

The following table lists all the third party devices and its associated operating systems supported in VCF Operations for networks.

| Data Source Version/Model | Supported Operating System (OS) and Versions | Supports Network Assurance and Verification feature (Network Map and Intents) |
|---|---|---|
| Amazon Web Services (Enterprise License Only) | Not Applicable | No |
| Arista 7050QX-32S, 7280TR | Arista EOS 4.26.*, 4.27* | Yes |
| Azure Subscription | Not Applicable | No |
| Brocade VDX 6740, VDX 6940, MLX, MLXe | NetIron 6.0.*, 6.2.* | Yes<br>Only on Brocade MLX |
| Check Point Firewall | Check Point GAiA R80.40, R81.10 | Yes |
| Cisco ACI | Fabric OS and iNXOS 3.2, 4.2.3, 4.2(7f), 5.2 (4d), 6.0(1g) | Yes<br>Only on Cisco ACI 4.2 (7f), 5.2 (4d) and 6.0(1g). |
| Cisco ASA X Series | ASA OS 9.8.1, 9.8(4), 9.12(4), 9.16(4) | Yes |
| Cisco Catalyst 3000, 4500, 6500, 9300, 9500 | IOS-XE 17.03 and IOS 12.1, 12.2, 12.4, 15.2.<br>• Cisco Catalyst 9500 is supported on IOS XE 17.6.4(MD) only.<br>• Cisco Catalyst 6500 is supported on IOS 15 only. | Yes |
| Cisco Nexus 2000***, 3000, 5000, 6000, 7000, 9000 | NX-OS 7.3, 8.2, 8.4, 9.2, 9.3, 10.3(1) | Yes<br>Only on Nexus 2000 (N2K-C2348UPQ-10GE), 5000, 7000, 9000 |

| Data Source Version/Model | Supported Operating System (OS) and Versions | Supports Network Assurance and Verification feature (Network Map and Intents) |
|---|---|---|
| Cisco UCS (Unified Computing System) Series B blade servers, Chassis, Fabric Interconnect, FEX | Cisco UCS Manager and NX-OS 3.2, 4.1, 4.2, 4.2(2a). | Yes<br>Only on Cisco UCS 4.1 and 4.2. |
| Cisco ASR 1K | Cisco IOS XE 15.5(3)S8, 15.5(3)S10, 16.06.05, 16.12.5, 17.9.4(MD). | Yes |
| Cisco ISR 4K | Cisco IOS XE 15.5(3)S9, 16.06.05, 17.4.1a, 17.9.4(MD) | Yes |
| Cisco ASR 9901 and 9910 | Cisco IOS XR 6.1.3, 6.5.1 | Yes |
| Dell S5248F-ON, FORCE10 MXL 10, FORCE10 S6000, S4048, PowerConnect 8024, Z9100, Dell S5200 | Dell Networking Operating System (DNOS) 10. | Yes<br>Only on Dell S5200 (OS10). |
| Fortinet FortiManager | FortiOS 6.4, 7.0 | No |
| F5 BIG - IP LTM | TMOS 13.1, 14.1, 15.1.4, 16.1 | Yes |
| HP Virtual Connect Manager 4.41, HP OneView 3.0 | | No |
| HPE 10508 | Comware | No |
| Huawei Cloud Engine 6800, 7800, 8800 | VRP 8.18 | No |
| Infoblox | Network Identity Operating System (NIOS) 8.0, 8.1, 8.2 | No |
| Juniper EX3300, QFX 51xx Series, 5K1, 10K | Junos 20.2 without QFabric | Yes<br>Only on Juniper QFX |
| Mellanox SN2010, SN2100, SN2410, SN2700, SN3420, SN3700c, and SN4600c. | Onyx 3.8.1304, 3.8.2306 | No |
| OpenShift 3.11 and 4.10.<br>**Note:**<br>You must add OpenShift version 4.x as individual kubernetes cluster using kube-config file. | Redhat Enterprise Linux | No |
| Palo Alto Networks Panorama | PanOS 9.1, 10.1, 10.2, 11.0 | Yes |

**Note:**

- *** VCF Operations for networks does not support Active-Active FEX (VPC) configuration for Cisco Nexus 2000 in Network Assurance and Verification.
- In addition to the mentioned supported OS versions, VCF Operations for networks supports the minor releases associated with major releases. For example, as Cisco IOS 15.2 is supported, all minor releases of this major release, such as 15.2(1), 15.2(2), etc., are also supported. However, newer major releases, such as 15.9, are not supported.
- In addition to the devices mentioned in the table, the following VMware products also supports Network Assurance and Verification feature (Network Map and Intents) in the latest version of VCF Operations for networks:
  - VMware NSX Manager
    - Distributed and Edge firewall
    - Multiple VTEPs
  - VMware vCenter
    - VMware vSphere Distributed Switch (VDS)
- You can get information about the required ports for all data sources supported in VCF Operations for networks at VMware Ports and Protocols.
- For third-party devices such as switches, routers, and firewalls, VCF Operations for networks uses SSH connections for fetching the configuration data. To learn about supported algorithms for such SSH connections, see Encryption Algorithms and Ciphers.

**Encryption Algorithms and Ciphers**

VCF Operations for networks supports several encryption algorithms and ciphers for data sources.

The following table lists the encryption algorithms and ciphers that are supported for data sources in Supported Products and Versions.

| Data sources | Encryption Algorithms and Ciphers |
|---|---|
| Arista switches<br>Brocade VDX switches<br>Check Point Firewall<br>Cisco ASA V Series<br>Cisco ASR and ISR<br>Cisco Catalyst 3000, 4500, 6500, 9300<br>Cisco Nexus N5000, N7000, N9000<br>Cisco UCS Fabric interconnect<br>Dell Force 10 S6000, PowerConnect 8024, S4048, S4810<br>Dell OS 10<br>HPE 5940, 10500<br>HP Virtual Connect Manager<br>Huawei Cloud Engine<br>Juniper switches<br>Mellanox | Key exchange algorithms:<br>• curve25519-sha256<br>• curve25519-sha256@libssh.org<br>• ecdh-sha2-nistp256<br>• ecdh-sha2-nistp384<br>• ecdh-sha2-nistp521<br>• diffie-hellman-group-exchange-sha256<br>• diffie-hellman-group16-sha512<br>• diffie-hellman-group18-sha512<br>• diffie-hellman-group14-sha256<br>Ciphers:<br>• aes128-ctr<br>• aes192-ctr<br>• aes256-ctr<br>• aes128-gcm@openssh.com<br>• aes256-gcm@openssh.com<br>MACs:<br>• hmac-sha2-256-etm@openssh.com<br>• hmac-sha2-512-etm@openssh.com<br>• hmac-sha1-etm@openssh.com<br>• hmac-sha2-256<br>• hmac-sha2-512<br>• hmac-sha1<br>Host key algorithms:<br>• ecdsa-sha2-nistp256<br>• ecdsa-sha2-nistp384<br>• ecdsa-sha2-nistp521<br>• rsa-sha2-512<br>• rsa-sha2-256<br>• rsa-sha2-512<br>• ssh-rsa |

| | **Note:**<br>VCF Operations for networks only supports ssh-rsa algorithms with 1024 bit keys. ssh-rsa algorithms with 2048 bit keys are not supported. |

## Supported VMware Managers

You can add VMware Managers into VCF Operations for networks and collect the details.

**Note:**

If a data source is deleted and then added again, allow for a five-hour buffer period.

### Add VMware vCenter

You can add VMware vCenter servers as data source in VCF Operations for networks.

- Your predefined roles in the VMware vCenter must have the **Global.Settings** privilege assigned at the root level. Also, you must propagate this privilege to the children roles.

  **Note:**
  When you add a role in the VMware vCenter, by default the role is created with three system-defined privileges: **System.Anonymous**, **System.Read**, and **System.View**. These privileges are not visible in the vSphere Client but are used to read certain properties of some managed objects. See the *vSphere Web Services API documentation* for more information.
- To configure and use IPFIX, you must have following VMware vCenter privileges:
  - **Distributed switch:** Modify, Port configuration operation and IPFIX Operation.
  - **dvPort group:** Modify, Policy operation and IPFIX Operation.

  **Note:**
  IPFIX is supported on the following VMware ESX versions:

  - 5.5 Update 2 (Build 2068190) and later.
  - 6.0 Update 1b (Build 3380124) and later.
  - VMware VDS 5.5 and later.
- To identify the VM to VM path, you must install VMware tools on all the VMs in the data center.

To know more about roles in VMware vCenter, see the *vSphere Security* guide.

Multiple VMware vCenter instances can be added to VCF Operations for networks to start monitoring data.

You can also add VMware vCenter data sources directly from VCF Operations by navigating to **Administration** > **Integrations**. To activate data sync between the VMware vCenter data source and VCF Operations for networks, select the data source, activate the **Network and Flow** option under **Network Operations**, and select a data collector. You can also enable NetFlow collection with the **Enable NetFlow (IPFIX) on this vCenter** option.

**Note:**

To enable Antrea IPFIX for collection of Supervisor, namespace, and VKS cluster flows, select **Enable Antrea (IPFIX) on this vCenter**.

Migration, editing, activating, deactivating data sources managed in VCF Operations is restricted.. If you are upgrading to VCF 9 from a previous version, the data source sync from VCF Operations for networks to VCF Operations does not happen automatically and must done explicitly by the user to see the data correctly on the **Network Inventory** dashboard.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under VMware Managers, select **VMware vCenter**.
4. Provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu.<br>**Note:**<br>You can add maximum 10 VMware vCenter Server per collector. |
| **IP Address/FQDN** | Enter the IP address ( IPv4 address or IPv6 address) or fully qualified domain name of the VMware vCenter. |

| Option | Action |
|---|---|
| | **Note:**<br>You must add the data source using either IP address or FQDN. Do not add the data source using both IP address and FQDN. |
| **Username** | Enter the user name with the following privileges:<br>• **Distributed Switch**: Modify<br>• **dvPort group**: Modify |
| **Password** | Enter the password for VCF Operations for networks software to access the VMware vCenter system. |

5. Click **Validate**.

   If the number of VMs discovered exceeds the capacity of the platform or a collector node or both, the validation fails. You will not be allowed to add a data source until you increase the brick size of the platform or create a cluster.

   The specified capacity for each brick size with and without flows is as follows:

| Brick Size | VMs | State of Flows |
|---|---|---|
| Large | 6k | Enabled |
| Large | 10k | Deactivated |
| Medium | 3k | Enabled |
| Medium | 6k | Deactivated |

6. Select **Enable Netflow (IPFIX) on this vCenter** to activate IPFIX.

   For more information on IPFIX, see IPFIX Configuration on VDS and DVPG.

   **Note:**

   - You cannot enable IPFIX on DVPGs with connected NSX-T Edges. After NSX-T is added to VCF Operations for networks, the system automatically detects and excludes these DVPGs.
   - vCenter IPFIX cannot be enabled for DVPGs managed by NSX
   - Overriding the **Switch IP address option** is not supported in VCF Operations for networks. VCF Operations for networks uses the host IP in flow records to configure flow enrichment.
   - Enabling uplink DVPGs is not supported.

7. Add advanced data collection sources to your VMware vCenter system.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

     If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

The VMware vCenter system appear on the homepage.

### Add VMware NSX Manager

NSX is designed to address the emerging application frameworks and architectures that have heterogeneous endpoints and technology stacks. In addition to vSphere, these environments may also include other hypervisors, containers, bare metal, and public clouds.

VCF Operations for networks supports NSX deployments where the VMs are managed by VMware vCenter.

#### Considerations

- VCF Operations for networks supports only the NSX setups in which VMware vCenter manages the ESX hosts.
- VCF Operations for networks supports NSGroups, NSX-T Firewall Rules, IPSets, NSX-T Logical Ports, NSX-T Logical Switches, NSX-T distributed firewall IPFIX flows, Segment, Group, and Policy Based VPN.
- VCF Operations for networks supports only NSX-T deployments. Support for NSX-V is removed starting with 9.0. If NSX-T is used instead of NSX, then only those entities are displayed. The same logic applies to the entities such as firewall rules, IPSets, and logical switches.
- With NSX-T 2.4 release, VCF Operations for networks supports NSX Declarative Policy Management which simplifies and automate network and security configurations through outcome-driven policy statements.

  **Note:**

  Micro-segmentation for Security Group is done based on NSX Policy data. But in case there is no corresponding NSX Policy Group, the standalone NS Group is included in the Micro-segmentation analysis.
- Ensure to add only local users in an NSX-T Federation setup.
- Verify that the user has both **Auditor** and **Network/Security Admin roles** are added for use with the data source.

#### Prerequisites

Here are the prerequisites for adding an NSX-T Manager as a data source:

- You must have at least the **Read only** privilege.
- You must add all the VMware vCenter associated with the NSX-T Manager as data sources in VCF Operations for networks.

  **Note:**
  If you add the NSX-T Manager before adding VMware vCenter, then VCF Operations for networks takes around four hours to stabilize.
- Ensure that there are no logical switches in the exclusion list in the Distributed Firewall (DFW). If there are any logical switches in this list, then the flows are not reported for any VMs attached to these logical switches.

#### Adding NSX-T Manager directly in VCF Operations

You can also add NSX-T data sources directly from VCF Operations by navigating to **Administration** > **Integrations**. To enable data sync between the NSX data source and VCF Operations for networks, select the data source, activate the **Network and Flow** option under **Network Operations**, and select a data collector. You can further expand data collection by enabling the **Enable IPFIX** and **Enable latency metric collection** options.

#### Procedure

1. Go to **Settings** > **Accounts and Data Sources** > **Add Source**.
2. Under **VMware Manager**, select **VMware NSX-T Manager**.
3. Provide the user credentials.

| Option | Action |
|---|---|
| Collector VM | Select a collector VM from the drop-down menu. |
| IP Address/FQDN | Enter the IPv4 management address or the FQDN details.<br>**Note:**<br>Currently, VCF Operations for networks does not support IPv6 NSX-T management addresses. |

<table>
<tr><th>Option</th><th>Action</th></tr>
<tr><td>Authentication Method</td><td>Select the authentication method from the drop-down menu.
<table>
<tr><td>Username/Password</td><td>Enter the user name and the password.</td></tr>
<tr><td>Certificate (Principal Identity)</td><td>• Certificate: Click Browse and upload the principal identity certificate.<br>• Private Key: Click Browse and upload the principal identity private key.<br>Note:<br>VCF Operations for networks does not support encrypted principal identity private key.</td></tr>
</table></td></tr>
</table>

**Note:**

- If you have more than one management node in a single NSX-T deployment, you must add only one node as a data source in VCF Operations for networks or use Virtual IP (VIP) (of those nodes). If you add more than one management node, then VCF Operations for networks might not function properly.
- Ensure that you use VIP when you add NSX-T as a data source. If you add a management node IP instead of a VIP, and later if you want to add a VIP or another management node IP, then you have to delete the existing data source to add the new VIP or the Management IP.
- Ensure that each management node in the cluster is reachable from the collector.
- If IPFIX is not required, the user must be a local user with audit level permissions. But if IPFIX is required, the user must have one of the following permissions: **enterprise_admin**, **network_engineer**, or **security_engineer**.

**Note:**
You must add the data source using either IP address or FQDN. Do not add the data source using both IP address and FQDN.

4. Click **Validate**.
5. Select **Enable IPFIX**to update the IPFIX settings on NSX-T. By selecting this option, VCF Operations for networks receives DFW IPFIX flows from NSX-T. For more information on enabling IPFIX, see Enable NSX-T IPFIX.

   **Note:**

   - DFW IPFIX is not supported in the Standard Edition of NSX-T.
   - From VMware Cloud Foundation 9.0 or later, if the DFW license is missing or if DFW is deactivated, VCF Operations for networks receives Switch IPFIX flows from NSX-T.

6. If you want to collect latency metrics data, select **Enable latency metric collection** check box. If you select this option, VCF Operations for networks receives latency metrics such as VTEP - VTEP, vNIC - pNIC, pNIC - vNIC, vNIC - vNIC from NSX-T.

   **Note:**

   - This option is available only for NSX-T 2.5 and later.
     - VTEP - VTEP is available from NSX-T 2.5 and later.
     - vNIC - pNIC, pNIC - vNIC, vNIC - vNIC are available from NSX-T 3.0.2 and later.
   - To enable latency metric collection, you must have **enterprise_admin** permission.
   - Ensure that the port 1991 is open on the collector to receive the latency data from the ESX node.

7. In the **Tags (Optional)** key-value pair text box, enter a key and a value.

Key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

- To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. For more details about the associated entities, see Working with Local Tags.

  If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

8. In the Nickname text box, enter a nickname.
9. In the Notes (Optional) text box, add a note if necessary.
10. Click **Submit**.

**Note:**

For NSX-T version 4.x and later, VCF Operations for networks doesn't support VM-VM path for federation deployment and VCF Operations for networks,Assurance and Verification.

## Examples for Queries

Here are some examples for queries related to NSX-T:

**Table 1305: Queries for NSX-T**

| Queries | Search Results |
|---|---|
| `NSX-T Manager where VC Manager=10.197.53.214` | NSX-T Manager where this particular VC Manager has been added as the compute manager. |
| `NSX-T Logical Switch` | Lists all the NSX-T Logical switches present in the instance of VCF Operations for networks. including the details on whether it is a system-created or a user-created switch. |
| `NSX-T Logical Ports where NSX-T Logical Switch = 'DB-Switch'` | Lists the NSX-T logical ports belonging to that particular NSX-T logical switch, DB-Switch. |
| `VMs where NSX-T Security Group = 'Application-Group'`<br>Or<br>`VMs where NSGroup = 'Application-Group'` | Lists all the VMs in that particular security group, Application-Group. |
| `NSX-T Firewall Rule where Action='ALLOW'` | Lists all the NSX-T Firewall Rules which have their action set as ALLOW. |
| `NSX-T Firewall Rule where Destination Security Group = 'CRM-Group'` | Lists the firewall rules where the CRM-Group is the Destination Security Group. The results include both Direct Destination Security Groups and Indirect Destination Security Groups. |
| `NSX-T Firewall Rule where Direct Destination Security Group = 'CRM-Group'` | Lists the firewall rules where the CRM-Group is the Destination Security Group. The results include only the Direct Destination Security Groups. |
| `VMs where NSX-T Logical Port = 'App_Port-Id-1'` | Lists all the VMs which have that particular NSX-T Logical Port. |
| `NSX-T Transport Zone` | Lists the VLAN and the overlay transport zone and the respective details associated with it including the type of the transport node.<br>**Note:**<br>VCF Operations for networks does not support KVM as a data source. |
| `NSX-T Router` | Lists the TIER 1 and TIER 0 routers. Click the router shown in the results to view more details associated with it including the NSX-T Edge Cluster and the HA mode. |

**Table 1306: Queries for NSX Policy**

| | |
|---|---|
| `NSX Policy Segment` | Lists all the NSX Policy Segments present in the instance of VCF Operations for networks. |
| `NSX Policy Manager` | Lists all the NSX Policy Manages present in the instance of VCF Operations for networks. |
| `NSX Policy Group` | Lists all the NSX Policy Groups present in the instance of VCF Operations for networks. |
| `NSX Policy Firewall` | Lists all the NSX Policy Firewalls present in the instance of VCF Operations for networks. |
| `NSX Policy Firewall Rule` | Lists all the NSX Policy Firewall Rules present in the instance of VCF Operations for networks. |
| `NSX Policy Firewall Rule where Action = 'ALLOW'` | Lists all the NSX Policy Firewall Rules which have their action set as ALLOW. |
| `NSX Policy Based VPN` | Lists all the NSX Policy Based VPNs present in the instance of VCF Operations for networks. |

**Note:**
If NSX-T 2.4 and VMware Cloud on AWS are added as data sources in your VCF Operations for networks, then to get the NSX entities, you must add `SDDC type = ONPREM` filter in your query. For example, `NSX Policy Based VPN where Tier0 = ‘’ and SDDC Type = ‘ONPREM’.`

## Support for NSX-T Metrics

The following table displays the VCF Operations for networks entities that support the NSX-T metrics currently and the widgets that display these metrics on the corresponding entity dashboards.

| Entities | Widgets on the Entity Dashboard | Supported NSX-T Metrics |
|---|---|---|
| Logical Switch | Logical Switch Packet Metrics<br>Logical Switch Byte Metrics | `Multicast and Broadcast Rx`<br>`Multicast and Broadcast Tx`<br>`Unicast Rx`<br>`Unicast Tx`<br>`Dropped Rx`<br>`Dropped Tx`<br>`Rx Packets (Total)`<br>`Tx Packets (Total)` |
| Logical Port | Logical Port Packet Metrics<br>Logical Port Byte Metrics | `Multicast and Broadcast Rx`<br>`Multicast and Broadcast Tx`<br>`Unicast Rx`<br>`Unicast Tx`<br>`Rx Packets (Total)`<br>`Tx Packets (Total)` |
| Router Interface | Router Interface Metrics | `Rx Packets`<br>`Tx Packets`<br>`Dropped Rx Packets`<br>`Dropped Tx Packets`<br>`Rx Bytes`<br>`Tx Bytes` |
| Firewall Rule | Firewall Rule Metrics | `Hit Count`<br>`Flow Bytes`<br>`Flow Packets` |

Here are some sample queries for NSX Metrics:

- `nsx-t logical switch where Rx Packet Drops > 0`
  This query lists all the logical switches where the count of the dropped received packets is greater than 0.
- `nsx-t logical port where Tx Packet Drops > 0`
  This query lists all the logical ports where the count of the dropped transmitted packets is greater than 0.
- `top 10 nsx-t firewall rules order by Connection count`
  This query lists the top 10 firewall rules based on the connection count(`Hit Count`).

  **Note:**

  Metric data from the real-time metrics component will continue to be collected even if the associated vCenter license of the NSX data source expires.

### Security Planning for NSX-T

To plan security for the NSX-T network, you can select the scope as **NSXT Layer2 Network** and use the following query:

```
plan NSX-T Layer2 Network '<NAME_OF_NSX_T_LOGICAL_SEGMENT>'
```

You can also obtain the same result by performing the following steps:

1. Select **Plan & Assess** > **Security Planning** from the left navigation from.
2. Select either **NSX-T L2 Network** or **NSX Policy Segment** as the scope from the drop-down menu.

   **Note:**
   NSX related entities such as **NSX-T L2 Network** and **NSX Policy Segment** are available in the scope. You can use these NSX related entities for security planning.

## NSX Projects and VPCs

VCF Operations for networks provides Enterprise administrators with complete visibility to NSX Projects and VPCs included in data sources.

### What are NSX Projects and VPCs

An NSX Project enables multi-tenancy for NSX network and security objects where each project is analogous to a tenant. A NSX VPC is an additional layer of tenancy that you can configure within an existing project. Both NSX Projects and VPCs are primarily configured and managed in NSX Manager by an administrator. For more information on NSX Projects and VPCs and how to add them in your NSX Manager environment, go to NSX Multi-tenancy.

**Note:**

VCF Operations for networks supports the discovery of Projects and VPCs created in NSX 9.0 and later

### NSX Projects and VPCs in VCF Operations for networks

VCF Operations for networks can now identify and extract data associated with Projects and VPCs included in the NSX-T Manager data source added to your environment. New entities, flow analytics, metrics, and network map topology options are added to VCF Operations for networks and used in Project and VPC specific dashboards and updated data included in existing NSX dashboards. You can receive a general overview of the Projects and VPCs from the **NSX Managers and VPCs** widget on the **Network Operations** page in the VCF Operations Console. By selecting **View Details** and expanding the entry for a given data source, you can view the Projects and VPCs associated with it. Clicking on the entry for a Project or VPC opens the dashboard page for that resource.

**Note:**

You can also view these dashboards from VCF Operations for networks.

You can use the data provided from Projects and VPCs to perform more granular analysis and troubleshooting of your NSX data sources. For example, you can use the uplink and downlink data on the VPC dashboard to troubleshooting connectivity issues.

Current limitations and specifics for VCF Operations for networks VPC usage include:

- Network map path search does not take into account the uplink named teaming policy associated with VLAN backed segments.
- VPC external IP NAT metrics are not captured or displayed in VCF Operations for networks, as these metrics are not exposed by NSX.
- In the Transit Gateway (TGW) dashboard, under router interface metrics, both TGW uplink and VPC uplink router interfaces are displayed. The metrics for the VPC uplink router interface correspond to the TGW downlink metrics.
- Only one service interface to NAT rule association is utilized and displayed in VCF Operations for networks,.

**Note:**

For VCF Operations for networks 9.0. network map path search does not take into account the uplink named teaming policy associated with VLAN backed segments.

**Disk Requirement for Projects and VPCs in VCF Operations for networks**

To support the efficient use of this feature, customers are recommended to increase the disk capacity of their VCF Operations for networks appliance by at least 500 GB if they are running at full capacity.

### Add VMware HCX

You can add VCF Operation HCX as a data source in VCF Operations for networks.

- You must have **Enterprise Administrator** access.
- You must add all the VCF Operations HCX Managers, including both source sites and destination sites, as data sources in VCF Operations for networks. You must also add the corresponding vCenter and NSX instances,

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **VMware Managers**, click **VMware HCX**.
4. In the **Add a New VMware HCX Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. Optional: In the **Nickname** text box, enter a nickname.
7. Optional: In the **Notes** text box, add a note if necessary.
8. Click **Submit**.

## Supported VMware Cloud Accounts

You can add VMware Cloud on AWS - vCenter account and NSX Manager account in VCF Operations for networks to monitor your VMware Cloud on AWS network.

**Note:**
VCF Operations for networks supports many types of NSX Manager accounts such as VMC on AWS NSX Manager, Azure VMware Solution NSX Manager, and Oracle Cloud VMware Solution NSX Manager.

To add VMware Cloud on AWS - vCenter account and NSX Manager account in VCF Operations for networks as data source, you must Manually Configure Data Sources for VMware Cloud on AWS.

### Manually Configure Data Sources for VMware Cloud on AWS

To monitor your VMware Cloud on AWS environment, you must set up the VCF Operations for networks collector to collect data from VMware Cloud on AWS, and add VMware Cloud on AWS -vCenter and VMware Cloud on AWS - NSX Manager as data sources.

### Preparing VCF Operations for networks to add VMware Cloud on AWS

You must setup VCF Operations for networks collector and configure firewall rules in VMware Cloud on AWS for communication and data collection.

### Set up VCF Operations for networks Collector for VMware Cloud on AWS

You must set up the VCF Operations for networks collector to collect data from VMware Cloud on AWS.

Deploy a VCF Operations for networks collector within every SDDC that needs to be added as a data source.

**Important:**

- Using a VCF Operations for networks collector deployed in one VMware Cloud on AWS SDDC to collect data from another VMware Cloud on AWS SDDC is not supported.
- You must deploy the VCF Operations for networks collector on a native VMware Cloud on AWS segment. Deploying a collector on extended segments is not supported.

1. Log in to VCF Operations for networks.
2. Navigate to **Settings** > **Infrastructure and Support** > **Add Collector VM**.
3. Copy the contents of the shared secret.

   You will require this during the deployment of VCF Operations for networks Collector OVA.
4. Deploy the VCF Operations for networks Collector OVA in the Compute Resource Pool of the VMware Cloud on AWS vCenter.

   Use the shared secret that you have generated.

   **Note:**
   For a single node SDDC in VMware Cloud on AWS, CPU resource reservation for the collector VM must be at least 1251 MHz.
5. Start the collector VM and follow the wizard to pair the collector with the VCF Operations for networks platform.

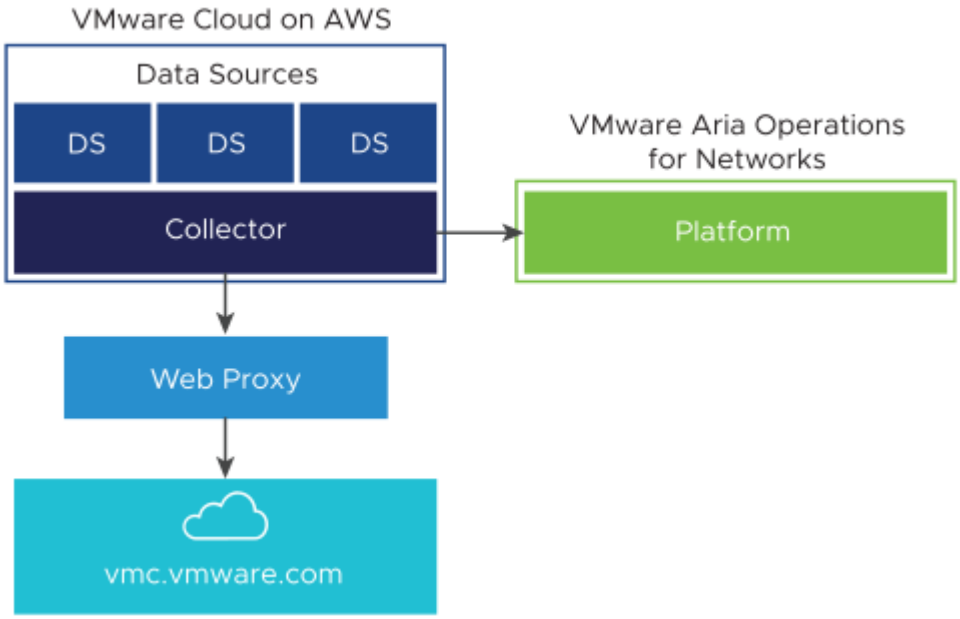
   **Note:**
   During this step, you must configure Web proxies and Firewall rules for VMware Cloud on AWS.
6. Validate that the collector pairs successfully with the platform.

### Configuring Web Proxies for VMware Cloud on AWS

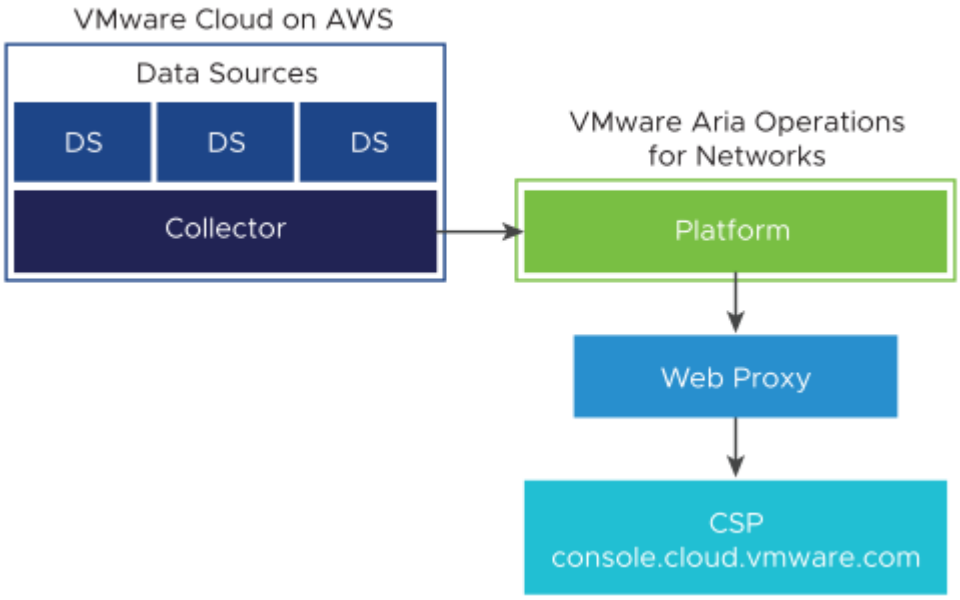
Depending on the scenario you are using, you must configure web proxies to connect to other entities (data sources, cloud service platforms, and so on) when the connection is made over the Internet.

#### Web Proxy Configuration Scenarios

- Scenario 1: Web Proxy not configured.
  You do not need any web proxy configuration.
- Scenario 2: When the Collector is in VMware Cloud on AWS and the Collector is using the web proxy to connect to `vmc.vmware.com`.
  You must enable the web proxy through the user interface (UI). To know how to configure web proxy, see Configuring Web Proxies.



- Scenario 3: When the Platform is on-premises and the Platform is using a web proxy to connect to CSP.
  You must use CLI to enable web proxy (HTTP anonymous and basic authentication web proxy only) in the Platform. To know about enabling web proxy using CLI, see set-web-proxy.



Create VMware Cloud on AWS Firewall Rules for VCF Operations for networks

You must create VMware Cloud on AWS groups and firewall rules to build communication with VCF Operations for networks.

**Prerequisites:**

- Deploy VCF Operations for networks platform and collector (for on-premise) or get the valid subscription (for cloud service).
- You must have required privileges. See Add VMware Cloud on AWS - vCenter and Add VMware Cloud on AWS NSX Manager.
- Deploy a VMware Cloud on AWS software-defined data center (SDDC) 1.8 and later with NSX-T networking.
- For the port requirements of incoming traffic, see VMware Ports and Protocols.
- Ensure you allow the HTTPS port 443 in the firewall to communicate between the Collector and the following domain:

  - `*.vmc.vmware.com`
- Ensure you allow the HTTPS port 443 in the firewall to communicate between the Platforms and the following domain:
  - `console.cloud.vmware.com`

**Configure Firewall Rules for communication between VCF Operations for networks platform and collector**

Configuring firewall rules in VMware Cloud on AWS includes:

- Creating a VMware Cloud on AWS group for VCF Operations for networks collector.
  a. Log in to VMware Cloud on AWS at https://vmc.vmware.com.
  b. On the **Networking & Security** tab, click **Inventory > Groups**.
  c. On the **Groups** card, click **COMPUTE GROUPS**, then click **ADD GROUP** and give the group a **Name** and an optional **Description**.
  d. Click **Set Members** to open the **Select Members** page.
  e. Provide the VCF Operations for networks collector VM details.
  You use this group in the firewall rules that you create later to allow communication between VMware Cloud on AWS NSX Manager and VCF Operations for networks.
- Create a firewall rule.
  a. Log in to the VMC Console at https://vmc.vmware.com.
  b. On the **Networking & Security** tab, click **Gateway Firewall**.
  c. On the **Gateway Firewall** card, click **Compute Gateway**, then click **ADD RULE** and give the new rule a **Name**.
  d. Enter the parameters for the new rule.
    - **Sources**: Enter the name of the VMware Cloud on AWS group containing the VCF Operations for networks collector IP address.
    - **Destinations**: Select **Any**.
    - **Services**: Select **HTTPS**, **DNS**, **DNS-UDP**, **NTP**, **ICMP**.
    - **Action**: Select **Allow**.
    - **Applied To**: Select **Internet Interface**.
    - **Logging**: Enable logging if required. Else this field is unchanged.
    The new rule is enabled by default. Slide the toggle to the left to deactivate it.
  e. Click **Publish**.

**Configure Firewall Rules for communication between collector and NSX Manager, and collector and vCenter**

1. Log in to the VMC Console at https://vmc.vmware.com.
2. On the **Networking & Security** tab, click **Gateway Firewall**.
3. On the **Gateway Firewall** card, click **Management Gateway**, then click **ADD RULE** and give the new rule a **Name**.
4. Enter the parameters for the new rule.
   - **Sources**: Enter the name of the VMware Cloud on AWS group containing the VCF Operations for networks collector IP address.
   - **Destinations**: Select **System Defined Groups**, search for NSX Manager, and then select the NSX Manager entry.
   - **Services**: Select **HTTPS (443)**.
   - **Action**: Select **Allow**.
   - **Logging**: Enable logging if required.
   By default, the new rule is enabled. Slide the toggle to deactivate it.
5. Click **Publish**.
6. Perform the same steps to configure a rule for the VMware vCenter Server.

   **Note:**
   Ensure to select VMware vCenter for the **Destinations** field in Step 4.

## Add VMware Cloud on AWS - vCenter

You can add VMware Cloud on AWS - vCenter as a data source in VCF Operations for networks.

- Obtain the credentials to add VMware Cloud on AWS - vCenter as a data source.
  - To obtain credentials for VMware Cloud on AWS, VMware Cloud on AWS Outposts, and VMware Cloud On Dell EMC, do the following steps:
    a. Log in to your VMware Cloud Services console, do one of the following depending on the service you are using:
       - For VMware Cloud on AWS, under **My Services**, click **VMware Cloud on AWS**.
       - For VMware Cloud on AWS Outposts, under **My Services**, click **VMware Cloud on AWS Outposts**.
       - For VMware Cloud On Dell EMC, under **My Services**, click **VMware Cloud On Dell EMC**.
    b. Click the name of the desired SDDC.
    c. Select the **Settings** tab, perform the following tasks:
       - Expand the **vCenter FQDN** panel and copy or note down the **vCenter FQDN**.
       - Expand the **Default vCenter User Account** panel and copy or note down the default user name (cloudadmin@vmc.local) and the default password.
  - To obtain credentials for Azure VMware Solution, Google Cloud VMware Engine, and Oracle Cloud VMware Solution, access the respective cloud consoles.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **VMware Cloud (VMC)**, select **VMC - vCenter**.
4. On the **Add a VMware Cloud (VMC) - VMware vCenter** page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter vCenter FQDN that you have retrieved from VMware Cloud Services. |
| **Username** | Enter the user name that you retrieved from the VMware Cloud Services. |
| **Password** | Enter the password that you retrieved from the VMware Cloud Services. |

5. Click **Validate**.
6. Optional: In the **Nickname** text box, enter a nickname.
7. Optional: In the **Notes** text box, add a note if necessary.
8. Click **Submit**.

### Add VMware Cloud on AWS NSX Manager

You can add VMware Cloud on AWS NSX Manager as a data source in VCF Operations for networks.

- Add VMware Cloud on AWS - vCenter
- Generate API tokens.
  To generate API tokens, you must have **Administrator** and **NSX Cloud Admin** service roles.
- Ensure that the platform node has direct internet access. Also, the firewall rules must allow the platform to connect to the internet. To know about firewall rules, see Create VMware Cloud on AWS Firewall Rules for VCF Operations for networks.
  If you are using a web proxy to access internet, you must configure the web proxy correctly. To know about web proxy configuration, see Configuring Web Proxies for VMware Cloud on AWS.
- To use all the available VCF Operations for networks features and to enable the DFW IPFIX on VMware Cloud on AWS NSX Manager, you must have the following privileges:

| Service | Organization Role | Service Role | Allowed Actions |
|---|---|---|---|
| vCenter on AWS | Org Member | **Administrator** and **NSX Cloud Admin** | Add Data Source, Enable IPFIX. |

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **VMware Cloud (VMC)**, click **VMC on AWS NSX Manager**.
4. In the **Add a VMware Cloud (VMC) on AWS NSX Manager** page, do the following:

| Option | Action |
|---|---|
| **VMC vCenter** | Select the corresponding VMware Cloud on AWS vCenter. |
| **Collector VM** | The System selects the collector automatically based on the selection of the VMware vCenter.<br>**Note:**<br>You must add the NSX Manager to the same collector VM as of the corresponding VMware Cloud on AWS vCenter. |
| **IP Address/FQDN** | Provide the IP address or the FQDN details.<br>**Note:**<br>You get the IP address from **Support** tab of vCenter on AWS SDDC Console. |
| **CSP Refresh Token** | Enter the API token that you have generated. |
| **Web Proxy (Optional)** | Select a web proxy from the **Web Proxy (Optional)** drop-down menu.<br>**Note:**<br>The **Web Proxy (Optional)** is visible only if you have configured a web proxy in VCF Operations for networks. |

5. Click **Validate**.
6. To collect IPFIX flows for DFW, select **Enable DFW IPFIX** check-box.

   **Note:**
   If you get error messages while enabling DFW IPFIX, see Unable to Enable DFW IPFIX troubleshooting topic.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

Add VMC on Dell EMC NSX Manager

You can add VMware Cloud on AWS on Dell EMC NSX Manager as a data source in VCF Operations for networks.

- Add VMware Cloud on AWS - vCenter
- Generate API tokens.
  To generate API tokens, you must have **Administrator** and **NSX Cloud Admin** service roles.
- Ensure that the platform node has direct internet access. Also, the firewall rules must allow the platform to connect to the internet. To know about firewall rules, see Create VMware Cloud on AWS Firewall Rules for VCF Operations for networks.
  If you are using a web proxy to access internet, you must configure the web proxy correctly. To know about web proxy configuration, see Configuring Web Proxies for VMware Cloud on AWS.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. In the **VMware Cloud (VMC)** category, select **VMC on Dell EMC NSX Manager**.
4. On the **Add Account or Source** page, do the following:

| Option | Action |
|---|---|
| **VMC vCenter** | Select the corresponding VMC vCenter. |
| **Collector VM** | The System selects the collector automatically based on the selection of the VMware vCenter.<br>**Note:**<br>You must add the NSX Manager to the same collector VM as of the corresponding VMware vCenter. |
| **IP Address/FQDN** | Provide the IP address or the FQDN details.<br>**Note:**<br>To get the IP address, you must contact VMC on Dell EMC Support. |
| **CSP Refresh Token** | Enter the API token that you have generated. |
| **Web Proxy (Optional)** | Select a web proxy from the **Web Proxy (Optional)** drop-down menu.<br>**Note:**<br>The **Web Proxy (Optional)** is visible only if you have configured a web proxy in VCF Operations for networks. |

5. Click **Validate**.
6. To collect IPFIX flows for DFW, select **Enable DFW IPFIX** check box.

   **Note:**
   If you get error messages while enabling DFW IPFIX, see Unable to Enable DFW IPFIX troubleshooting topic.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

### Add VMC on AWS Outposts NSX Manager

You can add VMC on AWS Outposts NSX Manager as a data source in VCF Operations for networks.

- Add VMware Cloud on AWS - vCenter.
- Generate API tokens.
  For vCenter, you must have **Administrator** and **NSX Cloud Admin** service roles assigned to you.
- Ensure that the platform node has a direct internet access. Also, the firewall rules must allow the platform to connect to the internet. To know about firewall rules, see Create VMware Cloud on AWS Firewall Rules for VCF Operations for networks.
  If you are using a web proxy to access internet, you must configure the web proxy correctly. To know about web proxy configuration, see Configuring Web Proxies for VMware Cloud on AWS.
- To use all the available VCF Operations for networks features and to enable the DFW IPFIX on VMware Cloud on AWS Policy Manager, you must have the following privileges:

| Service | Organization Role | Service Role | Allowed Actions |
|---|---|---|---|
| vCenter on AWS | Org Member | **Administrator** and **NSX Cloud Admin** | Add data source and enable IPFIX. |

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **VMware Cloud (VMC)**, click **VMC - AWS Outposts NSX Manager**.
4. In the **Add Accounts or Source** page, do the following:

| Option | Action |
|---|---|
| **VMC vCenter** | Select the corresponding VMware Cloud on AWS vCenter. |
| **Collector VM** | The System selects the collector automatically based on your selection of the VMware vCenter.<br>**Note:**<br>You must add the NSX Manager to the same collector VM as of the corresponding VMware vCenter. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details.<br>**Note:**<br>You get the IP address from **Support** tab of vCenter on AWS SDDC Console. |
| **CSP Refresh Token** | Enter the API token that you have generated. |
| **Web Proxy (Optional)** | Select a web proxy from the **Web Proxy (Optional)** drop-down menu.<br>**Note:**<br>The **Web Proxy (Optional)** is visible only if you have configured a web proxy in VCF Operations for networks. |

5. Click **Validate**.
6. To enable the distributed firewall to send IPFIX flow records to the collector, select the **Enable DFW IPFIX** check box.

   **Note:**
   If you get error messages while enabling DFW IPFIX, see Unable to Enable DFW IPFIX troubleshooting topic.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

Once the data collection starts, you can gain insight into VMC SDDCs on AWS Outposts. To learn more, see Viewing VMC on AWS Outposts SDDC Details.

### Add Azure VMware Solution NSX Manager

You can add Azure VMware Solution NSX Manager as a data source in VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. In the **VMware Cloud (VMC)** category, select **Azure VMware Solution NSX Manager**.
4. In the **Add Accounts or Source** page, do the following:

| Option | Action |
|---|---|
| **Collector VM** | The System selects the collector automatically based on your selection of the VMware vCenter.<br>**Note:**<br>You must add the NSX Manager to the same collector VM as of the corresponding VMware vCenter. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |

| Option | Action |
|---|---|
| **Password** | Enter the password. |

5. Click **Validate**.
6. To collect IPFIX flows for DFW, select **Enable DFW IPFIX** check box from the **Additional Information** section.

   **Note:**

   - If you get error messages while enabling DFW IPFIX, see Unable to Enable DFW IPFIX troubleshooting topic.
   - If you don't need IPFIX, you must be a local user with audit level permissions. But if you need IPFIX, you must have one of the following permissions: **enterprise_admin**, **network_engineer**, **security_engineer**, or **cloudadmin**.
   - The **cloudadmin** role does not have write access to NSX IPFIX MP API: `/api/v1/ipfix/collectorconfigs/<id>`
   - As this API is not allowed for **cloudadmin**, VCF Operations for networks will no longer support IPFIX flow collection for logical switches created using **Advanced Networking** tab in NSX.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

### Add Google Cloud VMware Engine NSX Manager

You can add Google Cloud VMware Engine NSX Manager as a data source in VCF Operations for networks.

Add VMware Cloud on AWS - vCenter.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. In the **VMware Cloud (VMC)** category, select **Google Cloud VMware Engine NSX Manager**.
4. On the **Add Accounts or Source** page, do the following:

| Option | Action |
|---|---|
| **Collector VM** | The System selects the collector automatically based on your selection of the VMware vCenter.<br>**Note:**<br>You must add the NSX Manager to the same collector VM as of the corresponding VMware vCenter. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To collect IPFIX flows for DFW, select **Enable DFW IPFIX** check box from the **Additional Information** section.

   **Note:**

   - If you get error messages while enabling DFW IPFIX, see Unable to Enable DFW IPFIX troubleshooting topic.
   - If you don't need IPFIX, you must be a local user with audit level permissions. But if you need IPFIX, you must have one of the following permissions: **enterprise_admin**, **network_engineer**, **security_engineer**, or **cloudadmin**.
   - The **cloudadmin** role does not have write access to NSX IPFIX MP API: `/api/v1/ipfix/collectorconfigs/<id>`
   - As this API is not allowed for **cloudadmin**, VCF Operations for networks will no longer support IPFIX flow collection for logical switches created using **Advanced Networking** tab in NSX.

7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

Add Oracle Cloud VMware Solution NSX Manager

You can add Oracle Cloud VMware Solution NSX Manager as a data source in VCF Operations for networks.

Add VMware Cloud on AWS - vCenter.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. In the **VMware Cloud (VMC)** category, select **Oracle Cloud VMware Solution NSX Manager**.
4. On the **Add Accounts or Source** page, do the following:

| Option | Action |
|---|---|
| **Collector VM** | The System selects the collector automatically based on your selection of the VMware vCenter.<br><br>**Note:**<br>You must add the NSX Manager to the same collector VM as of the corresponding VMware vCenter. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To collect IPFIX flows for DFW, select **Enable DFW IPFIX** check box from the **Additional Information** section.

   **Note:**

   - If you get error messages while enabling DFW IPFIX, see Unable to Enable DFW IPFIX troubleshooting topic.
   - If you don't need IPFIX, you must be a local user with audit level permissions. But if you need IPFIX, you must have one of the following permissions: **enterprise_admin**, **network_engineer**, **security_engineer**, or **cloudadmin**.
   - The **cloudadmin** role does not have write access to NSX IPFIX MP API: `/api/v1/ipfix/collectorconfigs/<id>`
   - As this API is not allowed for **cloudadmin**, VCF Operations for networks will no longer support IPFIX flow collection for logical switches created using **Advanced Networking** tab in NSX.

7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

## Supported AWS Outposts VMware Solution

In VCF Operations for networks, you can add your data sources that are deployed in the VMware Cloud on AWS on AWS Outposts Solution.

To gain insights about your data sources that are deployed in the VMware Cloud on AWS on AWS Outposts Solution, you must add the following data sources in VCF Operations for networks:

**Note:**
VCF Operations for networks does not support native AWS Outposts components that are attached to your VMware Cloud on AWS on AWS Outposts Solution SDDC.

1. Add VMware Cloud on AWS - vCenter
2. Add VMC on AWS Outposts NSX Manager
3. Add VMware HCX

**What to do Next**

Once the data collection starts, you can view the data source related information in VCF Operations for networks. To know about entity details, see Viewing Entity Details.

## Supported Azure VMware Solution

In VCF Operations for networks, you can add your data sources that are deployed in Azure VMware Solution (AVS).

> **Note:**
> VCF Operations for networks does not support native Azure components that are attached to your AVS SDDC.

To gain insights about your data sources that are deployed in Azure VMware Solution (AVS), you must add the following data sources in VCF Operations for networks:

1. Add VMware Cloud on AWS - vCenter
2. Add Azure VMware Solution NSX Manager
3. Add VMware HCX

**What to do Next**

Once the data collection starts, you can view the data source related information in VCF Operations for networks. To know about entity details, see Viewing Entity Details.

## Supported Oracle Cloud VMware Solution

In VCF Operations for networks you can add your data sources that are deployed in the Oracle Cloud VMware Solution.

> **Note:**
> VCF Operations for networks does not support native Oracle Cloud components that are attached to your Oracle Cloud VMware Solution SDDC.

To gain insights about your data sources deployed in the Oracle Cloud VMware Solution, you must add the following data sources in VCF Operations for networks:

1. Add VMware Cloud on AWS - vCenter
2. Add Oracle Cloud VMware Solution NSX Manager
3. Add VMware HCX

**What to Do Next**

Once the data collection starts, you can view the data source related information in VCF Operations for networks. To know about entity details, see the Viewing Entity Details.

## Supported Google Cloud VMware Engine

In VCF Operations for networks, you can add your data sources that are deployed in the Google Cloud VMware Engine.

> **Note:**
> VCF Operations for networks does not support native Google Cloud components that are attached to your Google Cloud VMware Engine SDDC.

To gain insights about your data sources deployed in Google Cloud VMware engine, you must add the following data sources in VCF Operations for networks .

1. Add VMware Cloud on AWS - vCenter
2. Add Google Cloud VMware Engine NSX Manager
3. Add VMware HCX

### What to Do Next

Once the data collection starts, you can view the data source related information in VCF Operations for networks. To know about entity details, see Viewing Entity Details.

## Supported VMware Cloud on Dell EMC Solution

In VCF Operations for networks, you can add your data sources that are deployed in vCenter on Dell EMC.

### Configuring VMware Cloud on Dell EMC in VCF Operations for networks

To get insights about data sources deployed in vCenter on Dell EMC, you must add the following data sources in VCF Operations for networks:

1. VMware vCenter
2. VMC on Dell EMC NSX Manager
3. VCF Operation HCX

| Sl. No. | Action | Procedure |
|---|---|---|
| 1 | Generate a shared secret for adding a collector. | Generate a Shared Secret |
| 2 | Deploy VCF Operations for networks collector in vCenter on Dell EMC. | Setting up Network Insight Collector (OVA)<br>Make sure to deploy a VCF Operations for networks collector within every SDDC that is added as a data source.<br>Also, for a single node SDDC in VMware Cloud on AWS, make sure the CPU resource reservation for the collector VM must be at least 1251 MHz.<br>**Important:**<br>During this step, you must configure Web proxies and Firewall rules for VMware Cloud on AWS.<br>When you deploy a VCF Operations for networks collector in vCenter on Dell EMC, the following scenarios are not supported:<br>• Using a VCF Operations for networks collector deployed in a VMware Cloud on AWS SDDC to collect data from another VMware Cloud on AWS SDDC.<br>• Deploying a collector on extended segments. You must deploy the VCF Operations for networks collector on a native VMware Cloud on AWS segment. |
| 3 | Add the VMware vCenter server deployed in VMware Cloud on Dell EMC in VCF Operations for networks. | Add VMware Cloud (VMC) - vCenter |
| 4 | Generate an API token from vCenter services. | To generate API tokens, you must have **VMC on Dell EMC Administrator** and **VMC on Dell EMC Cloud Admin role for NSX** service roles. |
| 5 | Add vCenter on Dell EMC NSX Manager in VCF Operations for networks. | Add VMC on DELL EMC NSX Manager |
| 6 | (Optional) Add VMware HCX in VCF Operations for networks. | Add VMware HCX |

### Viewing Entity Details

Once the data collection starts, you can view the data source related information in VCF Operations for networks.

### Generate a Shared Secret

You can generate and import the VCF Operations for networks collector virtual appliance.

Generate a shared secret and import the VCF Operations for networks collector virtual appliance:

1. Log into the VCF Operations for networks UI.
2. Select **Infrastructure and Support**. **Settings** > **Infrastructure and Support**.
3. Scroll down and click **Add Collector VM**.
4. Copy the shared secret and click **Done**.

## Supported Containers

You can add containers into VCF Operations for networks.

### Add Tanzu Kubernetes Grid Integrated Edition

You can add Tanzu Kubernetes Grid Integrated Edition as a data source and fetch your cluster details in VCF Operations for networks.

- You must ensure that:
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- You must have the **pks.clusters.admin** privilege.
- You must add the corresponding NSX-T Manager.

> **Note:**
> VCF Operations for networks supports only VMware Tanzu Kubernetes Grid Integrated Edition out of all the VMware Tanzu Kubernetes Grid offerings.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under Containers, select **TKGI**.
4. On the Add a new TKGI Account or Source page, provide the following details:

| Field Name | Description |
|---|---|
| NSX-T Manager | Select the NSX-T Manager that supports the underlying networking for the Tanzu Kubernetes Grid Integrated Edition deployment. |
| Collector VM | VCF Operations for networks automatically selects the corresponding collector VM associated with the chosen NSX-T Manager.<br>**Note:**<br>The collector VMs that are added as a NetFlow collector are not available in the list. |
| API Hostname (FQDN) | Enter the FQDN details of the Tanzu Kubernetes Grid Integrated Edition API server. |
| Username | Enter the Tanzu Kubernetes Grid Integrated Edition user name that has access to the clusters.<br>**Note:**<br>The user must have the `pks.clusters.admin` privileges. |

| Field Name | Description |
|---|---|
| Password | Enter the password.<br><br>**Note:**<br>Currently passwords having special characters like `&, (, ), |, <, >, ` are not supported. |

5. Click **Validate**.

   You see the `Validation Successful` message.

6. Optional: In the **Nickname** text box, enter a nickname.

7. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

     If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

8. Optional: In the **Notes** text box, add a note if necessary.

9. Click **Submit**.

   If you see the `One or more Kubernetes Cluster Master hosts are not reachable from Collector VM` error message, run the following commands on the collector VM:

   a) `tkgi login -a` *`TKGI_API_Server`* `- u` *`username`* `-p` *`password`* `-k`
   b) `tkgi clusters`

      Ensure that the cluster status is `succeeded`.

   c) `tkgi cluster` *`Kubernetes_Cluster_Name`*
   d) `telnet` *`Kubernetes_Master_HostKubernetes_Master_port`*

      Verify the primary host is able to connect.

   e) Repeat step c and step d for all Kubernetes cluster that were discovered from step b.

**Add Kubernetes**

You can add Kubernetes as a data source and fetch your Kubernetes Cluster details into VCF Operations for networks.

- You must ensure that:
  – The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
  – The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- You have cluster admin role with read permissions.
- You have added NSX-T Manager in VCF Operations for networks.

**Note:**
The Kubernetes Cluster and the corresponding NSX-T Manager must be added to the same collector VM.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under Containers, select **Kubernetes**.
4. In the Add a new Kubernetes Account or Source page, provide the following details:

| Field Name | Description |
|---|---|
| NSX-T Manager | Select the NSX-T Manager that supports the underlying networking for Kubernetes. |
| Collector VM | VCF Operations for networks automatically selects the corresponding collector VM associated with the chosen NSX-T Manager.<br>**Note:**<br>The collector VMs that are added as a NetFlow collector are not available in the list. |
| Kubeconfig | Click **Browse** and upload the Kubernetes configuration file that has Kubernetes cluster details. For more information about the format of the Kubeconfig configuration file, refer to the Kubernetes documentation.<br>**Note:**<br>The user configured in the Kubeconfig file must have the **List** and **Watch** privileges. |

5. Click **Validate**.
   You see the `Validation Successful` message.
6. Optional: In the **Nickname** text box, enter a nickname.
7. Optional: In the **Notes** text box, add a note if necessary.
8. Click **Submit**.

VCF Operations for networks can now fetch the Kubernetes cluster details.

Go to the Kubernetes Dashboard and view the details, see Viewing Kubernetes Details.

**Add OpenShift**
You can add OpenShift as a data source and fetch your OpenShift details into VCF Operations for networks.

You must ensure that:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You have added NSX-T Manager in VCF Operations for networks.

**Note:**
OpenShift and the corresponding NSX-T Manager must be added to the same collector VM.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under Containers, select **OpenShift**.
4. On the Add a new OpenShift Account or Source page, provide the following details:

| Field Name | Description |
|---|---|
| NSX-T Manager | Select the NSX-T Manager that supports the underlying networking for OpenShift. |
| Collector VM | VCF Operations for networks automatically selects the corresponding collector VM associated with the chosen NSX-T Manager.<br>**Note:**<br>The collector VMs that are added as a NetFlow collector are not available in the list. |
| Kubeconfig | Click **Browse** and upload the Kubernetes configuration file that has Kubernetes cluster details. For more information about the format of the Kubeconfig configuration file, refer to the Kubernetes documentation.<br>**Note:**<br>The user configured in the Kubeconfig file must have the **List** and **Watch** privileges. |

5. Click **Validate**.
6. Optional: In the **Nickname** text box, enter a nickname.
7. Optional: In the **Notes** text box, add a note if necessary.
8. Click **Submit**.

VCF Operations for networks can now fetch the OpenShift details.

See the details on the Viewing Kubernetes Details.

## Supported Firewalls

VCF Operations for networks supports the following firewalls.

### Add Palo Alto Networks Panorama

You can add Palo Alto Networks Panorama as a data source in VCF Operations for networks.

You must ensure that:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You have **admin role** with XML API access. For more details, see Palo Alto Firewall.

In the **Panorama** UI, perform the following steps to add an admin role for XML API.

1. Select **Panorama** > **Admin Roles**.
2. Click **Add** to add a new admin role.
3. In the **The Admin Role Profile** window, enter the name to the role and select **Panorama**.
4. Click the **Web UI** tab and deactivate all entries.
5. Click the **XML API** tab and deactivate all entries, except **Configuration** and **Operational Requests**.
6. Click **OK** to close the window.
   The new admin role appears in the list.

7. Click **Commit**.
8. Assign this role to an administrator account or create a new user and assign this role to the new user.

**Note:**
VCF Operations for networks does not currently fetch local Palo Alto Network policies that are directly defined in the devices.

**Note:**
VCF Operations for networks does not support the Palo Alto Panorama integration with multiple NSX managers.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Firewalls**, click **Palo Alto Networks Panorama**.
4. In the **Add a New Palo Alto Networks Panorama Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

VCF Operations for networks supports the following features of Palo Alto firewall:

- Neighbor Discovery (LLDP)
- Layer 3 Routing (IPv4)
- Virtual Router
- Virtual Wire (Supported only in network assurance and verification)
- Security Policy
- Security Zone
- Virtual System (Not supported in network assurance and verification)

  **Note:**
  VCF Operations for networks does not support inter-vsys routing of Palo Alto firewalls.
- High Availablility. This feature has limited support and is not supported in network assurance and verification.

  **Note:**
  VIP interfaces are not supported.

### Add Check Point Management Server

VCF Operations for networks supports Check Point Security Manager (SmartCenter) and the Check Point Multi-Domain Security (MDS) Management Servers.

- You must ensure that:
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- VCF Operations for networks requires read-only privileges for the Web-API access for fetching most of the Check Point data. There are few exceptions as follows:
  - If a non-VSX physical gateway is attached to the management server, the user should have read-write access privileges for the Web API. This is required to fetch the gateway routes for using the `run script` Web API for the VM-VM path computation.
  - If a VSX gateway is attached to the management server, the user should have the SSH access with the same password. In addition, the user should have access to the CLI command `vsx_util view_vs_conf`. This command is used to fetch the VSX gateway routes for the VM-VM path computation.
  - For MDS server IP as data-source, the user should have the Web API access to all domains including the MDS domain and the global domain. It is required to fetch rules, policy packages and other data from all the domains.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under the **Firewall** group, click **Check Point Management Server**.
4. In the **Add a New Check Point Management Server Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details.<br>**Note:**<br>If you are adding the Check Point MDS Management server, you must provide the IP of the MDS server. You cannot add the domain management server IP of an MDS server as an individual data source. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   - To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

     If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

VCF Operations for networks supports the following features of Check Point firewall:

- VLAN
- Layer 3 Routing (IPv4)
- Virtual Wire (in network assurance and verification)
- Security Policy
- Security Zone (in network assurance and verification)
- NAT (Network Address Translation). This feature is not supported in network assurance and verification.
- Cluster (Not supported in network assurance and verification)
- Virtual System (Not supported in network assurance and verification)

**Note:**
VCF Operations for networks does not support Check Point Virtual Switch and Virtual Router.

**Configuring and Managing Dropped Flow Alerts for Palo Alto and Check Point Firewalls in VCF Operations**
You can use VCF Operations to handle any dropped flow alerts that you receive from your Palo Alto or Check Point firewalls.

- Verify that log management is added as a data source in VCF Operations for networks.
- Verify that log management is configured as Syslog server for the firewalls. For more information, see Update Syslog server for Check Point and Palo Alto firewalls.
- Verify that port 514 and port 1514 are open. These ports are used to communicate with log management.

When log management reports a dropped flow that is received from a Check Point or a Palo Alto firewall device VCF Operations sends an alert.

1. Download and install the VMware Cloud Foundation Content Pack for VCF Operations for networks from the VCF Solutions Catalog.
2. To check for received dropped flow alerts, navigate to **Operate** > **Alerts** and expand **Log Fallback Object**.
3. To identify the cause for the dropped flow, select the alert, and select **analyze logs** from the **Recommendations** section.

   The **Analyze Logs** tab of the **Logs** page opens. The **Stream** tab contains the details of the dropped flow alert, which you can use to troubleshoot the issue.

**Add Cisco ASA**
You can add Cisco ASA as a data source in VCF Operations for networks.

- You must ensure that:
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The user account has the privilege to enter the enable mode by using enable mode password. The user password must be same as the password used for the enable mode of Cisco ASA.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Firewall** group, click **Cisco ASA**.
4. In the **Add a New Cisco ASA Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |

| Option | Action |
|---|---|
| | **Note:**<br>The user should have the enable mode privilege to set terminal length to `0`, and for switching security context. |
| **Password** | Enter the password.<br>**Note:**<br>Ensure that you enter the same password as the one that you used for the enable mode of Cisco ASA. |

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

VCF Operations for networks supports the following features of Cisco ASA:

- VLAN
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- Security Policy
- Security Zone
- Global Policy
- Multiple Context (Not supported in network assurance and verification)

**Add a Fortinet FortiManager**
In VCF Operations for networks, you can add Fortinet FortiManager as a data source.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You have at least the **Restricted User** role with access to all ADOMs and policy packages.
- You have the **rpc-permit read-write** access enabled from Command Line Interface (CLI).
  To configure the **rpc** permission, use the following command in FortiManager CLI:

```
config system admin user
edit "<administrator name>"
set rpc-permit [none | read | read-write ]
end
```

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Firewalls**, select **Fortinet FortiManager**.
4. On the **Add a New Fortinet FortiManager Account or Source** page, enter the required information:

| Option | Action |
|---|---|
| **Collector VM** | Select the collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP Address or the FQDN details. |
| **Username** | Enter the user name you want to use for this data source. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

VCF Operations for networks supports the following features of Fortinet FortiGate firewall:

- Layer 3 Routing (IPv4)
- Security Policy
- Security Zone
- NAT (Network Address Translation)
- Virtual Domain

## Supported Converged Infrastructures

VCF Operations for networks supports adding a few third party converged infrastructures.

### Add Cisco UCS Manager

You can add Cisco UCS Manager as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

**Note:**

Cisco Virtual Machine Fabric Extender (VM-FEX) is not supported in VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Converged Infrastructures**, select **Cisco UCS Manager**.
4. In the Add a Cisco UCS Account or Source page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To enable a richer data collection, click the **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on the version of SNMP that you selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

VCF Operations for networks supports the following features of Cisco UCS Manager:

- Neighbor Discovery (CDP and LLDP). This feature is supported only in network assurance and verification.
- Layer 2 Switching
- VLAN
- Fabric Extender (FEX)
- End Host Mode
- Blade Server
- Rack Server (Not supported in network assurance and verification)

**Add HP Virtual Connect Manager**

You can add HP Virtual Connect Manager as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Converged Infrastructures**, click **HP Virtual Connect Manager** and provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

4. Click **Validate**.
5. Optional: In the **Nickname** text box, enter a nickname.
6. Optional: In the **Notes** text box, add a note if necessary.
7. Click **Submit**.

VCF Operations for networks supports the following features of HP Virtual Connect Manager:

- Enclosure / Chassis
- Blade Server
- Interconnect
- Uplink Port
- VLAN

**Add HP One View Manager**

You can add HP One View Manager as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Converged Infrastructures**, click **HP One View Manager** and provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

4. Click **Validate**.
5. Optional: In the **Nickname** text box, enter a nickname.
6. Optional: In the **Notes** text box, add a note if necessary.
7. Click **Submit**.

VCF Operations for networks supports the following features of HP One View Manager:

- Enclosure / Chassis
- Blade Server
- Interconnect
- Network Set

## Supported Routers and Switches

VCF Operations for networks supports several third party routers and switches.

**Add Arista Switch SSH**
You can add Arista Switch SSH as a data source in VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, select **Arista Switch SSH** .
4. In the **Add a New Arista Switch SSH Account or Source** page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details.<br>**Note:**<br>You must enter the same IP/FQDN that you have used in VMware NSX Manager to configure this switch. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

VCF Operations for networks supports the following features of Arista Switch:

- Neighbor Discovery (LLDP)
- Layer 2 Switching
- VLAN
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- Redundancy (VARP and VRRP)
- Access Control List (in network assurance and verification)
- EVPN-VXLAN
- NSX Controller Hardware VTEP (Not supported in network assurance and verification)

**Add a Brocade Switch**
You can add Brocade switches as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

You must have the following permissions:

- **Read-only user**: VCF Operations for networks requires read-only third-party device credentials (passwords) to access the SSH data. This user needs to have the **Network Operator** role. These passwords are added when configuring the third-party data provider in VCF Operations for networks user interface.

- **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click the Brocade switch that you want to add and provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

**Note:**
To know about the supported products and versions, see Supported Products and Versions.

4. Click **Validate**.
5. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

VCF Operations for networks supports the following features of Brocade switches:

- Brocade MLX
  - Neighbor Discovery (LLDP)
  - Layer 2 Switching
  - VLAN
  - Layer 3 Routing (IPv4)
  - VRF (Virtual routing and forwarding)
  - Access Control List (in network assurance and verification)
- Brocade VDX 6740 and VDX 6940
  - Neighbor Discovery (LLDP)
  - Layer 2 Switching
  - VLAN
  - Layer 3 Routing (IPv4)
  - VRF
  - Redundancy (VRRP)

### Add a Cisco ASR 9901/9910 Router

You can add Cisco ASR 9901/9910 routers as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

You must have the following permissions:

- **Read-only user**: VCF Operations for networks requires read-only third-party device credentials (passwords) to access the SSH data. This user needs to have the **Network Operator** role. These passwords are added when configuring the third-party data provider in VCF Operations for networks user interface.
- **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click **Cisco ASR 9901/9910**.
4. In the **Add a New Cisco ASR 9901/9910 Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

   **Note:**
   Ensure you are using the correct supported versions. To know about the supported products and versions, see Supported Products and Versions.

5. Click **Validate**.
6. Optional: To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

- To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

  If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

VCF Operations for networks supports the following features of the Cisco ASR 9901/9910 Router:

- Neighbor Discovery (CDP and LLDP)
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- Access Control List (in network assurance and verification)
- MPLS - BGP VPNv4

**Add a Cisco ASR 1000 Series Router**

You can add a Cisco ASR 1000 series router as a data source in VCF Operations for networks.

- You must verify the following information:
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You must have the following permissions:
  - **SSH user**: VCF Operations for networks requires an SSH account with a privilege level 15 to get the CLI data. You can have a privilege level lower than 15 but the SSH account must be able to execute all show commands that VCF Operations for networks needs like `show running-config view full`.

    For the privilege levels less than 15, you must configure the following command to run the show command `show running-config view full`:

    ```
    privilege exec level <privilege_level> show running-config view full
    ```

    For example: `privilege exec level 10 show running-config view full`.
  - **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click the **Cisco ASR 1000**
4. In the **Add a New Cisco ASR 1000 Account or Source** page provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

**Note:**

Ensure you are using the correct supported versions. To know about the supported products and versions, see Supported Products and Versions.

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

VCF Operations for networks supports the following features of the Cisco ASR 1000 Series Router:

- Neighbor Discovery (CDP and LLDP)
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- Redundancy (HSRP and VRRP)
- Access Control List (in network assurance and verification)

**Add a Cisco Catalyst Switch**

You can add Cisco Catalyst switches as a data source in VCF Operations for networks.

- You must verify the following information:
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You must have the following permissions:
  - **SSH user**: VCF Operations for networks requires an SSH account with a privilege level 15 to get the CLI data. You can have a privilege level lower than 15 but the SSH account must be able to execute all show commands that VCF Operations for networks needs like `show running-config view full`.

    For the privilege levels less than 15, you must configure the following command to run the show command `show running-config view full`:

    ```
    privilege exec level <privilege_level> show running-config view full
    ```

    For example: `privilege exec level 10 show running-config view full`.
  - **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click the Catalyst switch you want to add and provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

   **Note:**
   Cisco Catalyst 9300 Series switches that are part of the StackWise virtual environment must be added as a single switch in VCF Operations for networks.

4. Click **Validate**.
5. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) Form the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

VCF Operations for networks supports the following features of Cisco Catalyst Switch:

- Neighbor Discovery (CDP and LLDP)
- Layer 2 Switching
- VLAN
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)

- Redundancy (HSRP and VRRP)
- Access Control List (in network assurance and verification)
- MPLS - BGP VPNv4

**Add a Cisco ISR 4000 Series Router**

You can add a Cisco ISR 4000 series router as a data source in VCF Operations for networks.

- You must verify the following information:
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You must have the following permissions:
  - **SSH user**: VCF Operations for networks requires an SSH account with a privilege level 15 to get the CLI data. You can have a privilege level lower than 15 but the SSH account must be able to execute all show commands that VCF Operations for networks needs like `show running-config view full`.

    For the privilege levels less than 15, you must configure the following command to run the show command `show running-config view full`:

    ```
    privilege exec level <privilege_level> show running-config view full
    ```

    For example: `privilege exec level 10 show running-config view full`.
  - **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click the **Cisco ISR 4000**.
4. In the **Add a New Cisco ISR 4000 Account or Source** page provide the required information.

| Option | Action |
|---|---|
| **Collector (Proxy) VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |
| **Web Proxy (Optional)** | Select a web proxy from the drop-down menu.<br>**Note:**<br>The **Web Proxy (Optional)** is visible only if you have configured a web proxy in VCF Operations for networks. |

**Note:**

Ensure you are using the correct supported versions. To know about the supported products and versions, see Supported Products and Versions.

5. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
7. Click **Validate**.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

VCF Operations for networks supports the following features of the Cisco ISR 4000 Series Router:

- Neighbor Discovery (CDP and LLDP)
- Layer 2 Switching
- VLAN
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- Redundancy (HSRP and VRRP)
- Access Control List (in network assurance and verification)

**Add a Cisco Nexus Switch**

You can add Cisco Nexus switches as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

You must have the following permissions:

- **Read-only user**: VCF Operations for networks requires read-only third-party device credentials (passwords) to access the SSH data. This user needs to have the **Network Operator** role. These passwords are added when configuring the third-party data provider in VCF Operations for networks user interface.
- **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

  **Note:**
  If you have a Nexus device configured with multiple Virtual Device Contexts (VDC) then you need to individually specify VDC associated IP address as separate data sources.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click the Cisco Nexus switch that you want to add.
4. In the Add a new Cisco N5K Account or Source page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

**Note:**
To know about the supported products and versions, see Supported Products and Versions.

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

VCF Operations for networks supports the following features of the Cisco Nexus Switch:

- Neighbor Discovery (CDP and LLDP)
- Layer 2 Switching
- VLAN
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)

- Redundancy (HSRP and VRRP)
- Access Control List (in network assurance and verification)
- Fabric Extender (FEX)
- BGP-EVPN (not supported in network assurance and verification)
- Gateway Load-Balancing protocol (GLBP). This feature is not supported in network assurance and verification.

**Add a Dell Switch**

You can add Dell switches as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

You must have the following permissions:

- **Read-only user**: VCF Operations for networks requires read-only third-party device credentials (passwords) to access the SSH data. This user needs to have the **Network Operator** role. These passwords are added when configuring the third-party data provider in VCF Operations for networks user interface.
- **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click the Dell devices that you want to add and provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

   **Note:**
   If you want to add Dell S4048, Z9100, or S6000 devices in VCF Operations for networks as a data source and if that Dell device is running on OS 10, then you must select **Dell OS10** as an account or a source type while adding that Dell device as a data source in VCF Operations for networks.

4. Click **Validate**.
5. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.

- **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
- **Fixed Schedule** - Select the days and set the time to schedule the interval.

7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

     If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

For Dell OS10 Switches, Enable telemetry on Dell OS10 switches.

VCF Operations for networks supports the following features of the following Dell switches:

- Dell Froce10 MXL 10
  – Neighbor Discovery (LLDP)
  – Layer 2 Switching
  – VLAN
  – Layer 3 Routing (IPv4)
  – Redundancy (VRRP)
- Dell OS10 (S4048, S5200)
  – Neighbor Discovery (LLDP)
  – Layer 2 Switching
  – VLAN
  – Layer 3 Routing (IPv4)
  – VRF (Virtual routing and forwarding)
  – Redundancy (VRRP)
- Dell PowerConnect 8024
  – Neighbor Discovery (LLDP)
  – Layer 2 Switching
  – VLAN
  – Layer 3 Routing (IPv4)
- Dell S4048 (OS9)
  – Neighbor Discovery (LLDP)
  – Layer 2 Switching
  – VLAN
  – Layer 3 Routing (IPv4)
  – Redundancy (VRRP)
- Dell S6000 and Dell Z9100
  – Neighbor Discovery (LLDP)
  – Layer 2 Switching
  – VLAN
  – Layer 3 Routing (IPv4)
  – VRF
  – Redundancy (VRRP)

### Enabling Telemetry on Dell OS10 Switches

You can enable streaming telemetry on the Dell OS10 switches to integrate buffer statistics and tracking on Dell switches.

After adding Dell OS10 switches as a data source in VCF Operations for networks , you can enable streaming telemetry on the switches to send buffer related information to the VCF Operations for networks collector.

The VCF Operations for networks collector ingests this telemetry information and extracts the `per-port egress buffer peak utilization` metric. This metric can be used to diagnose network congestion at a particular switchport in the network, and to identify application performance issues.

If the peak buffer utilization exceeds a threshold of 10 MB, VCF Operations for networks raises the `Switchport Buffer Threshold Exceeded Event` alert.

Here is an example on how to configure streaming telemetry on a Dell OS10 switch:

```
telemetry
enable
!
destination-group dg03
 destination Aria-Ops-for-Networks Collector IP 50000
!
subscription-profile sp03
 sensor-group buffer 15000
 destination-group dg03
 encoding gpb
 transport grpc no-tls
 source-interface ethernet1/1/1
end
```

For more information about configuring telemetry, see the Dell EMC User Guide.

**Add a Huawei 6800/7800/8800 Series Switch**

VCF Operations for networks supports multiple series of Huawei Cloud Engine switches.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

You must have at least Read-Only permissions.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, select **Huawei 6800/7800/8800 Series** and provide the required details.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

4. Click **Validate**.
5. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

6. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

You can use the following features of VCF Operations for networks with Huawei devices or routers.

- VM-VM path
- VM Underlay topology
- Huawei Router or Switch dashboard
- Metrics: Switch port and router interface metrics
- Dashboards
  – Huawei Router or Switch
  – Router Interfaces
  – Port Channels
  – Switch Ports
  – Routes
- High availability: supports M-LAG (Multi-Chassis Link Aggregation) and VRRP (Virtual Router Redundancy Protocol)
- Searches
  – VRF (Virtual routing and forwarding) of Huawei
  – Router Interface of Huawei
  – Switch port of Huawei
  – Port Channel of Huawei
  – Routes in Huawei
- Huawei NetStream data monitoring

VCF Operations for networks supports the following features of Huawei routers:

- Neighbor Discovery (LLDP)
- Layer 2 Switching
- VLAN
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- Redundancy (VRRP)

**Add an HPE 5940/10508 Switch**

You can add HPE 5940/10508 switches as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

You must have the following permissions:

- **Read-only user**: VCF Operations for networks requires read-only third-party device credentials (passwords) to access the SSH data. This user needs to have the **Network Operator** role. These passwords are added when configuring the third-party data provider in VCF Operations for networks user interface.
- **Read-only SNMP user**: VCF Operations for networks uses SNMP to collect metrics information from third-party devices (switches, routers, firewalls, and so on). The third-party devices must have SNMP enabled and be accessible from VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click **HPE 5940/10508**.
4. In the **Add a New HPE 5940/10508 Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.

- **Fixed Schedule** - Select the days and set the time to schedule the interval.

8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

VCF Operations for networks supports the following features of the HPE 5940/10508 switch:

- Neighbor Discovery (LLDP)
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)

**Add a Juniper Switch**

You can add Juniper switches as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under the Routers & Switches, select **Juniper EX/QFX**.
4. In the Add a new Juniper EX/QFX Account or Source page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:

   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

VCF Operations for networks supports the following features of Juniper switch:

- Neighbor Discovery (LLDP)
- Layer 2 Switching
- VLAN
- STP (Spanning Tree Protocol ). This feature is supported only in network assurance and verification.
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- Redundancy (VRRP). This feature is supported only in network assurance and verification.
- Access Control List (in network assurance and verification)
- EVPN (Ethernet VPN). This feature is not supported in network assurance and verification.

**Add a Mellanox Switch**

You can add SN2010, SN2100, SN2410, SN2700, SN3420, SN3700c, and SN4600c Mellanox switches as a data source in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Routers & Switches**, click **Mellanox SN2100/SN2410** .
4. In the **Add a New Mellanox Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

VCF Operations for networks supports the following features of Mellanox switch:

- Neighbor Discovery (LLDP)
- Layer 2 Switching
- VLAN
- Layer 3 Routing (IPv4)
- VRF (Virtual routing and forwarding)
- M-LAG (Multi-Chassis Link Aggregation), where the Peer IP is shown
- MAGP (Multi-active Gateway Protocol)

**Add a New Generic Router or Switch**
You can add a generic router or switch to VCF Operations for networks by uploading its device configuration file. VCF Operations for networks uses the information in the device configuration file to provide insight for the router or switch and show the router or switch in the VM-VM path.

- You must verify that the data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You must create the device configuration file in `.zip` format using the SDK provided by the VCF Operations for networks. To create a device configuration file, see https://github.com/vmware/network-insight-sdk-generic-datasources.
  The device configuration file contains information about entities, such as router interfaces, routes, switch ports, VRFs, switch device information, and so on.

**Note:**
You must upload a new configuration file whenever there is a configuration change. VCF Operations for networks does not automatically collect data from the generic router or switches.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under Routers & Switches, click **Generic Routers & Switches**.
4. On the **Add a New Generic Router/Switch** page, modify the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a Collector VM from the drop-down menu. |
| **Device Configuration File** | Select and upload the configuration file `(.zip)` created using the SDK.<br>**Note:**<br>After you upload a device configuration file in VCF Operations for networks, you cannot modify the information of the uploaded device configuration file. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |

5. Click **Validate**.
6. Optional: In the **Nickname** text box, enter a nickname.
7. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

### Edit a Generic Router or Switch

In VCF Operations for networks, you can modify the configuration of an existing generic router or switch by uploading new configuration file.

Create a device configuration file in `.zip` format using the SDK provided by the VCF Operations for networks. A device configuration file contains information about entities like Router Interfaces, Routes, Switch Ports, VRFs, Switch Device Information, and so on. To create a device configuration file, see https://github.com/vmware/network-insight-sdk-generic-datasources.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click the three dots icon next to the generic router or the generic switch data source you want to edit and click **Edit**.
3. Click **Replace File** and upload the new device configuration file.
4. Optional: To view your uploaded device configuration file, click **Upload History**.

   You can view, download, and delete the last five uploaded device configuration files.

5. Click **Validate**.
6. Optional: In the **Nickname** text box, change the nickname.
7. Click **Submit**.

## Supported Other Data Sources

VCF Operations for networks supports other data sources like Cisco ACI.

### Add Cisco ACI

You can add Cisco ACI (Application Centric Infrestructure) as a data source in VCF Operations for networks. This feature is available only for the enterprise license users.

- You must verify the following information:
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- To connect to the APIC controller REST API over HTTPS, you must have access to all the tenants and have the read-only privilege.
- For SNMP, you must have the read-only permission.
- To authenticate Cisco ACI, you must have a local user role with the following privileges:
  - Security Domain: all
  - Role: admin
  - Access: read

  For details on how to create a local user in Cisco ACI, see the Access, Authentication, and Accounting section in the *Cisco APIC Security Configuration Guide*.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Others**, select **Cisco ACI**.
4. In the **Add a new Cisco ACI Account or Source** page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Provide the IP address of an APIC controller in the cluster.<br>**Note:**<br>You do not have to add the individual switches in the ACI fabric. |
| **Username** | Enter the user name.<br>**Note:**<br>• If the user is a domain user, then you must add `apic:` before the user name. For example, if the user name is **user1** and if the user belongs to the domain **domain1** then specify the user name as `apic:domain1\\user1`. The domain name is case-sensitive.<br>• If you want to use a local user account when default authentication method is set to TACACS, then you must add `apic#fallback\\` before the user name. For example, if the local user name is user2, then specify the user name as `apic#fallback\\user2`. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. To enable a richer data collection, click **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

7. Define the polling interval for the configuration data collection. You can set the polling interval from 10 minutes to 7 days.
   - **Preset** - Select the interval time from the predefined time set.
   - **Custom Interval** - Set a value and select **Minutes**, **Hours**, and **Days**.
   - **Fixed Schedule** - Select the days and set the time to schedule the interval.
8. Optional: In the **Nickname** text box, enter a nickname.
9. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.
   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.
   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.
   If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
10. Optional: In the **Notes** text box, add a note if necessary.
11. Click **Submit**.

Cisco ACI is added as a data source in VCF Operations for networks.

**Note:**

VCF Operations for networks supports the following features of Cisco ACI:

- Neighbor discovery (CDP and LLDP)
- Endpoint group (EPG)
- L3Out EPG
- EPG gateway
- Bridge domain
- VRF
- IPv4 routing
- Contract (in network assurance and verification)

The following features are not supported:

- Fabric extender (FEX)
- IPv6
- Layer 3 EVPN
- Multi-pod
- Multi-site

### Supported Cisco ACI Contracts

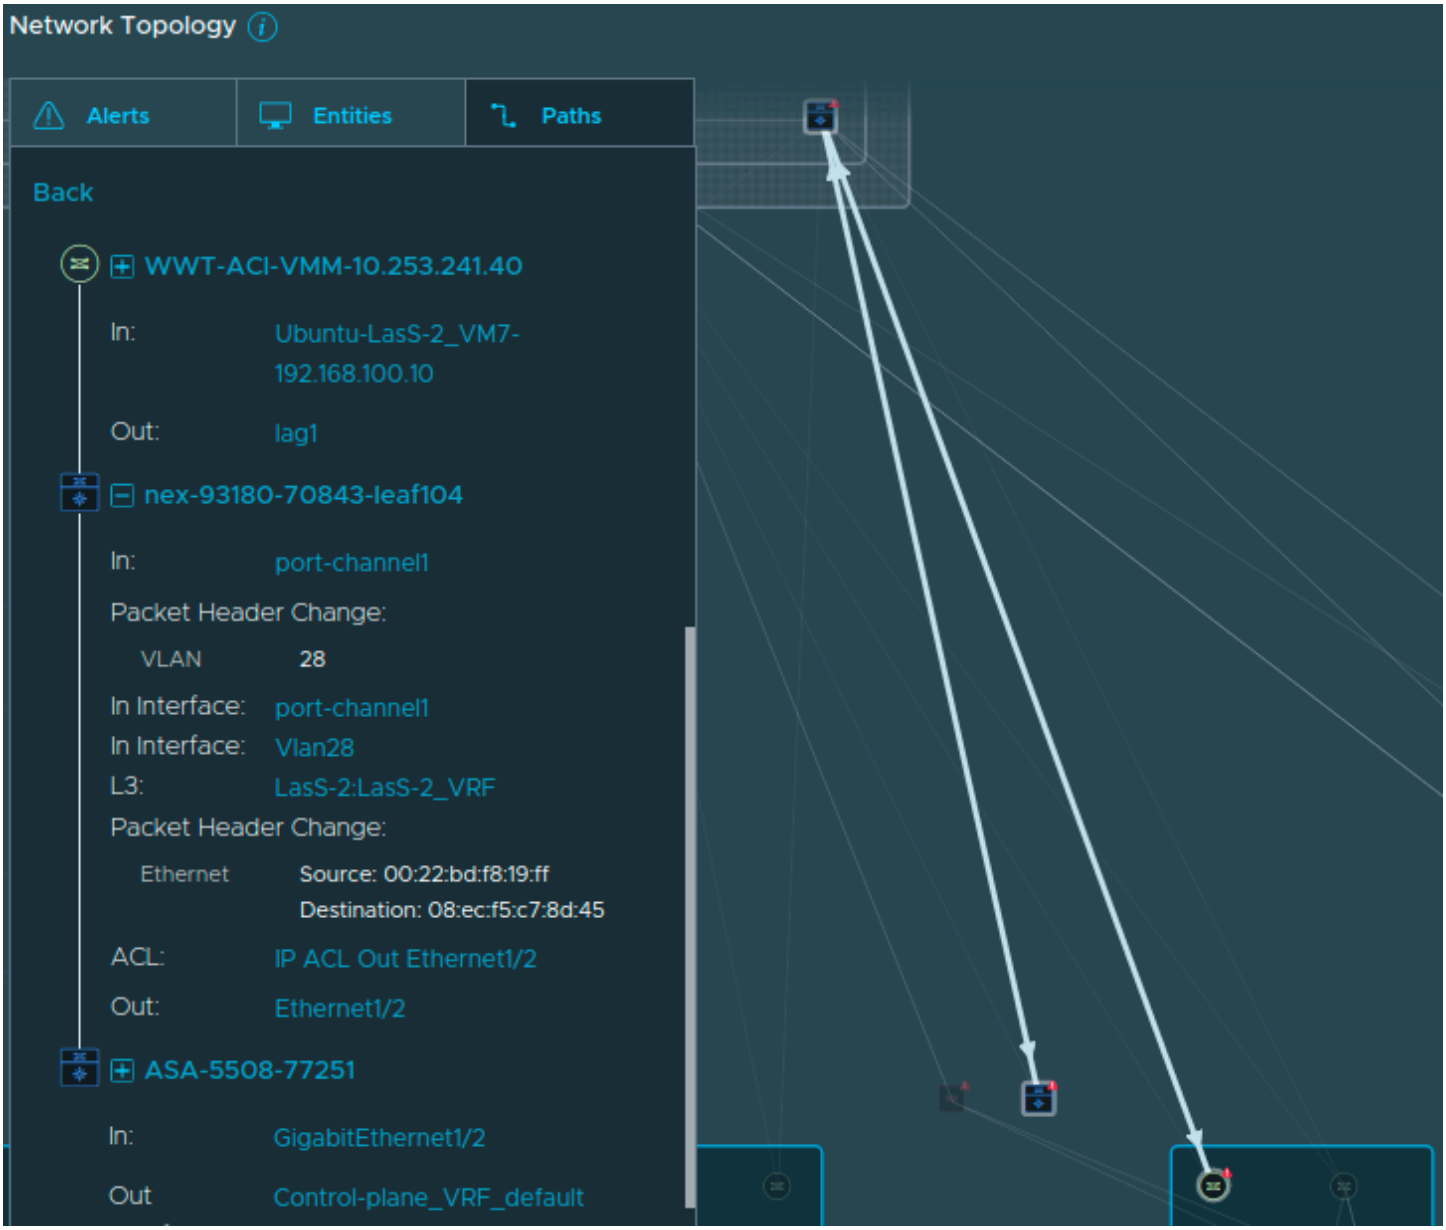
You use Cisco ACI contracts to control traffic flow within the Cisco ACI fabric between EPGs. These contracts are configured between EPGs, or between EPGs and L3out.

When you add a Cisco ACI setup as a data source, VCF Operations for networks supports the following Cisco ACI contracts:

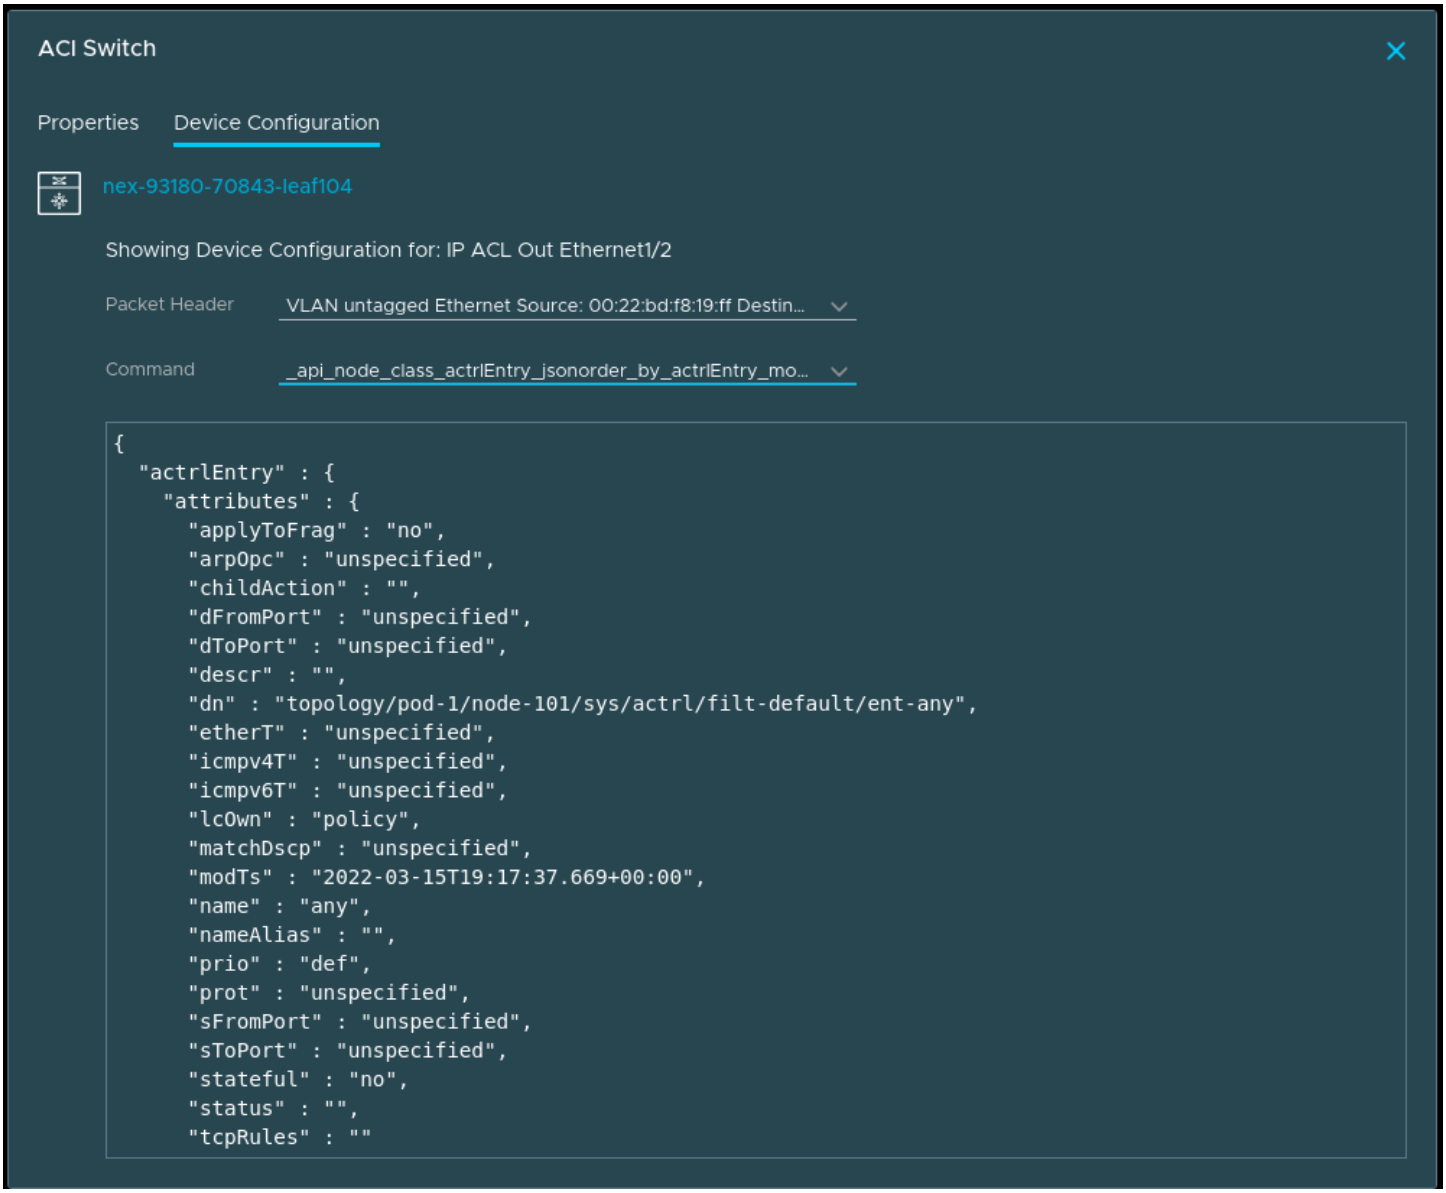
- Intra-EPG Contract
- Intra-EPG Isolation
- VRF Unenforced Mode
- Intra-VRF Contract
- Inter-VRF Contract (Scope - Global)
- Inter-VRF Contract (Scope - Tenant)
- Intra-App Profile Contract
- Inter-App Profile Contract
- Contract Inheritance
- Taboo Contract
- vzAny Contract
- East-West Traffic via Common Tenant
- Preferred Group
- Application EPG to L3Out EPG Contract in VRF
- Application EPG to L3Out EPG Contract between VRF
- Intra Ext-EPG Contract
- Intra Ext-EPG Isolation
- L3Out to L3Out Contract
- Contract between L3Out in common tenant and another VM in different tenant

You see these contracts applied on the Network Map when you search for the traffic traversing Cisco ACI switches.

An example of an access control contract on Cisco ACI:



An example of the device configuration of Cisco ACI:



The following contracts are not supported in VCF Operations for networks:

- Out-of-Band Contract
- Policy Based Redirect
- Stateful Filter in Contract

To learn more about Cisco ACI contracts, see the Cisco ACI Contract Guide.

## Supported Physical Flow Collectors

VCF Operations for networks supports addition of physical flow collectors and enables configuration of switches to push sFlows and NetFlows records to the collector.

### Add a Physical Flow Collector for NetFlow and sFlow

You can add a physical flow collector and configure the switches to send sFlow and NetFlow records to the collector.

The collector VM that is used for NetFlow or sFlow is a dedicated collector. It cannot be used for any other data source.

**Note:**

- Do not use a physical flow collector to collect VeloCloud Edge flow records.

- VCF Operations for networks listens to sFlow records on port 6343 of the collector appliance. Therefore, make sure to send sFlow records to port 6343 of the collector.

If any other data source is added to the collector, it is not available as a Physical Flow Collector for sFlow and NetFlow.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Flows**, select **Physical Flow Collector (Netflow, sFlow)**.
   sFlows are accepted only on a physical collector.
4. On **Add a new Physical Account or Source** page, click **Add Collector VM**.
5. The **Add a new Operations for Networks Data Collector virtual appliance** window is displayed. Click **Copy** to copy the shared secret to import the collector service ova in your VMware vCenter.
6. Click **Done**.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

**Note:**
VCF Operations for networks collects the packet samples for sFlow and therefore cannot show the complete metrics for the flows.

Configure the switches to push the flows to the Physical Flow Collector. For more information, see Flow Support for Physical Servers topic.

- Define the destination (Collector IP address that you added in VCF Operations for networks).
- Set the port for the flow collector.
- Assign poll interval.

**Note:**
The procedure to configure the switch depends on the type of switch that you want to configure. For more information, see the respective switch documentation.

## Supported Log Servers

VCF Operations for networks supports addition of VCF Operations for logs. This feature is available only for the enterprise license users.

**Configure VCF Operations for logs**
You must add the VCF Operations for logs data source in VCF Operations for networks to get the dropped flow notifications for the Check Point and Palo Alto firewalls.

To configure the VCF Operations for logs dat source, you must do the following:

- Add the VCF Operations for logs data source
- Install Content Pack and Enable Alerts
- Configure Webhook
- Update Syslog server for Check Point and Palo Alto firewalls

### Add VCF Operations for logs

VCF Operations for logs collects syslog messages from Check Point and Palo Alto firewalls. After you add the VCF Operations for logs data source in VCF Operations for networks, the dropped flow notifications for these firewall devices are shown in VCF Operations for networks.

Ensure that you have the API user permissions to install, configure, and manage the content pack.

Install the content pack and enable alerts.

**Note:**

VCF Operations for networks supports addition of VCF Operations for logs 8.0 to 9.0. Make sure you add the supported version of VCF Operations for logs as a data source in VCF Operations for networks. For VCF Operations for logs 9.1 support, please see Viewing Dropped Flow Alert for Check Point and Palo Alto.

When the firewall devices are configured to send syslog messages to VCF Operations for logs and when any policy is affected on these devices, VCF Operations for logs filters deny/drop action messages and sends notification to VCF Operations for networks. VCF Operations for networks consumes these notifications and creates dropped flow events with firewall and flow details.

1. Create or reuse a VCF Operations for logs user with access to the APIs of VCF Operations for logs.
2. Go to **Settings** > **Accounts and Data Sources**.
3. Click **Add Source**.
4. Click **Operations for Logs** under **Log Servers**.
5. On the **Add a New Operations for Logs Server Account or Source** page, click **Instructions** next to the page title. A pop-up window appears providing the prerequisites for adding the VCF Operations for logs data source and the instructions to enable the Webhook URL on VCF Operations for logs.
6. Enter the required details.

| Name | Description |
|---|---|
| Collector VM | Select the IP address of the data collector that you have deployed for the data collection process. |
| IP Address / FQDN | Enter the IP address or the FQDN of the data source. |
| User Name | Enter the user name you want to use for a particular data source. |
| Password | Enter the password for the data source. |
| Authentication Provider | Select the respective authentication provider for the credentials that you have provided. |

7. After the data source is created, a pop-up window is displayed providing the webhook URL and the steps that have to be performed to enable this URL on VCF Operations for logs. Copy the Webhook URL.

   **Note:**
   The Webhook URL, which is generated after the addition of the data source, is used in VCF Operations for logs.
8. Log in to VCF Operations for logs with the credentials that were used for adding this data source. Enable alerts in the VCF Operations for logs application and select the preconfigured Webhook. To ensure that the integration is successful, click **Send Test Alert**.

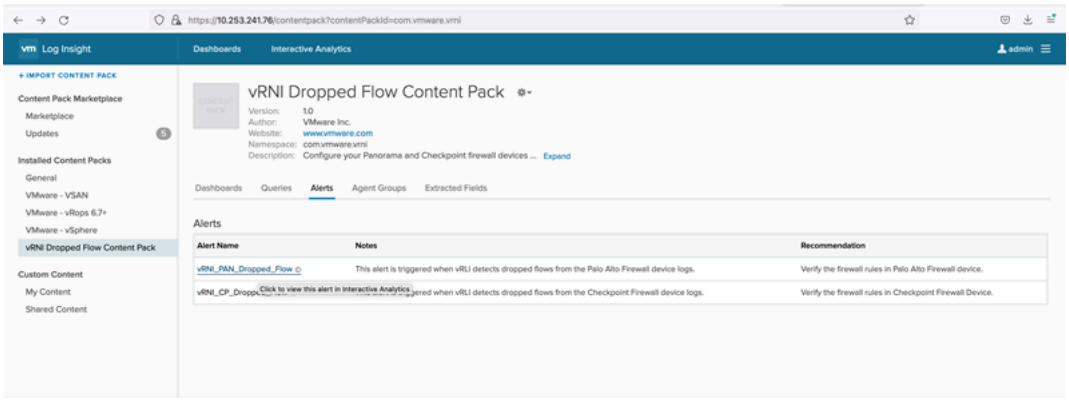
### Install Content Pack and Enable Alerts

Install the content pack before you add VCF Operations for logs data source in VCF Operations for networks.

1. Log in to VCF Operations for logs and from the left pane, click **Content Packs** > **Import Content Pack**.
2. On the **Import Content Pack** page, browse for **Operations for Networks Dropped Flow Content Pack** and click **Import**.

   **Note:**
   VCF Operations for networks supports VCF Operations for logs version 8.0 to 8.8. Make sure you add the supported version of VCF Operations for logs as a data source in VCF Operations for networks.

- After you have installed the content pack and have added the VCF Operations for logs data source in VCF Operations for networks, you can enable the alerts to send information.
- If you have installed the content pack for the first time, view and enable alerts in the **Operations for Networks Dropped Flow Content Pack** page. Click **Send Test Alert** to ensure that the integration is successful.



Configure Webhook

You can configure the Webhook serve in VCF Operations for logs.

1. Log in to VCF Operations for logs and from the left pane, select **Webhook** under **Alerts**.
2. On the **Webhook** page, click **New Webhook** to add a new webhook.
3. Enter the required details.

| Name | VCF Operations for networks Dropped Flow Alert |
|---|---|
| Endpoint | Custom |
| Webhook URL | Copied from Operations for Networks add source page. For example, `https://webhook_user:**********@vrni-appliance/webhooks/loginsight/alert` |
| Content Type | JSON |
| Action | Post |
| Webhook Payload | `{`<br>`"AlertType": 1,`<br>`"AlertName": "${AlertName}",`<br>`"SearchPeriod": ${SearchPeriod},`<br>`"HitOperator": ${NumHits},`<br>`"messages": ${messages}`<br>`}`<br>**Note:**<br>Ensure to add the Webhook payload exactly as given above. |

4. Update the `/etc/hosts` file to connect VCF Operations for networks with the Webhook server.

   **Note:**
   You must have the `sudo/root` permission to update the `/etc/hosts` file.

   For example,

```
ssh root@10.253.241.105
VMware Cloud Foundation Operations for Logs
root@10.253.241.105's password:
Last login: Tue Jun 14 03:31:14 UTC 2022 from 172.31.1.73 on pts/0
Last login: Tue Jun 14 09:15:08 2022 from 172.31.1.46
root@vRLI-8 [ ~ ]# cat /etc/hosts
# Begin /etc/hosts (network card version)
# End /etc/hosts (network card version)
# VAMI_EDIT_BEGIN
# Generated by Studio VAMI service. Do not modify manually.
127.0.0.1   vRLI-8 localhost
```

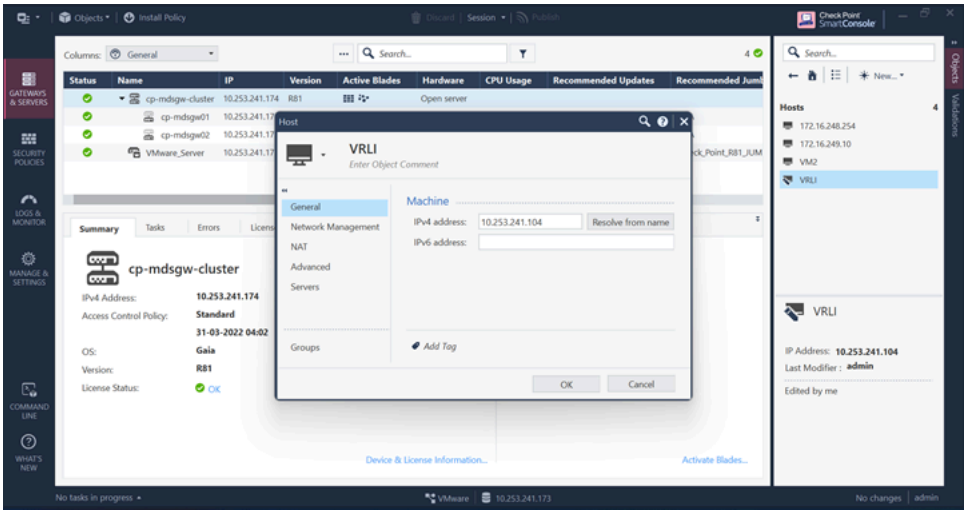
```
10.253.241.206 vrni-appliance
::1    vRLI-8 localhost ipv6-localhost ipv6-loopback
# VAMI_EDIT_END
root@vRLI-8 [ ~ ]#
```

Update Syslog server for Check Point and Palo Alto firewalls

To configure new syslog server for a Check Point firewall, refer to the Check Point page for Working with Syslog Servers.

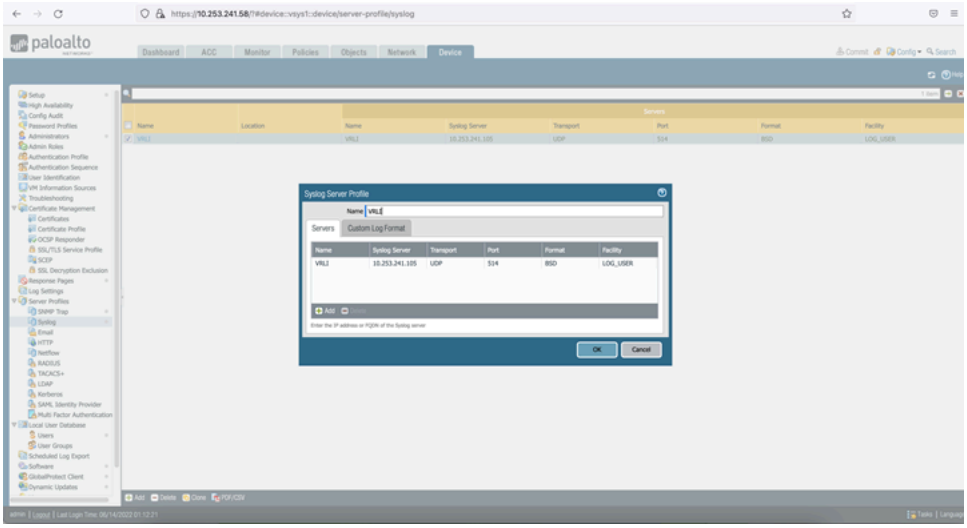
To update the existing syslog server:

1. Open **Smart Console** and click **Object Categories** > **Network Object** > **Hosts**.
2. Select and update the appropriate host.



To configure VCF Operations for logs as the syslog server for a Palo Alto firewall:

1. Login to the Palo Alto web user interface and click **Device** > **Server Profile** > **Syslog**.
2. Update the existing server or click **Add** to add a new server.
3. After adding or updating the server, save the changes.



## Supported DNS Data Providers

VCF Operations for networks supports DNS providers like Infoblox.

### Add Infoblox

VCF Operations for networks allows you to add Infoblox Grid as a DNS data provider in VCF Operations for networks.

You must verify the following information:

- The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
- The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.

Infoblox DNS offers an advanced solution to manage and control DNS. It uses Infoblox Grid to ensure that the DNS is highly available throughout the network. The DNS data from Infoblox is used only for enriching the flows where either the source or the destination IP addresses are associated with the physical devices.

The Infoblox DNS data co-exists with the DNS data that is imported by using CSV.

Infoblox does not need a dedicated collector. If you have configured an Infoblox DNS data source on a collector, you can use the same collector to configure other data sources on it.

**Considerations**

- VCF Operations for networks supports only single-grid mode for Infoblox in the current release.
- Only A Records are supported in the current release. Shared A Records are not supported currently.
- The DNS enrichment is supported only for the IP addresses that are marked as physical in the current release.
- If there are multiple FQDNs for a single physical IP address, all FQDNs are returned.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **DNS**, click **Infoblox**.
4. On the Add a new Infoblox Account or Source page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.

   **Note:**
   Ensure that you have the `API Privilege` to access the Infloblox APIs.

6. Optional: In the **Nickname** text box, enter a nickname.
7. Optional: In the **Notes** text box, add a note if necessary.
8. Click **Submit**.

The Infoblox DNS data source is added to the environment.

## Supported Load Balancers

VCF Operations for networks supports addition of load balancers as data source.

**Add F5 BIG-IP**

VCF Operations for networks supports the router and load balancer functionalities of F5 BIG-IP. The features like VM-VM path, high availability, VRFs, Routes, Router Interfaces, Switch Ports, Port Channels, Switch Port metrics, VRF Dashboard, Switch Dashboard, Router dashboard, and Assurance and Verification (Load Balancing and Source Network Address Translation in path search, and intents) are supported. For search on the F5 BIG IP entities, use the query string `F5 BIG-IP Data Source`. VCF Operations for networks does not support LLDP neighbors or the neighboring devices in the VM-VM path.

- You must verify the following information:
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.

  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You must have the following permissions:
  - The **Guest** role or **Read Only** permissions with **access to all partitions**.
  - Access to F5 BIG-IP REST API.

    **Note:**

    - VCF Operations for networks does not require **root** user privilege.

    **Note:**
    VCF Operations for networks supports only Local Traffic Module (LTM). Enabling other modules can prevent VCF Operations for networks to collect data from the device.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Load Balancers**, click **F5 BIG-IP**.
4. In the **Add a New F5 BIG-IP Account or Source** page, provide the required information.

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. Optional: To enable a richer data collection, click the **Use SNMP (recommended for richer data collection)** check box, and do the following:
   a) From the **SNMP Version** drop-down menu, select an SNMP version. Depending on which version of SNMP you have selected, do the following:

| Option | Action |
|---|---|
| 2c | In the **Community String** text box, enter a community string. |
| 3 | 1. Enter **Username**, Context Name.<br>2. From the **Authentication Type** drop-down, select an authentication type and enter the **Authentication Password**.<br>3. From the **Privacy Type** drop-down, select a privacy type and enter the **Privacy Password**. |

**Note:**
Ensure that you configure SNMP on the F5 BIG-IP UI console.

1. Log in to F5.
2. Navigate to **System** > **SNMP**.
3. Go to **SNMP** > **Agent** > **Access (v1, v2c)**.
4. Enter the community string.
5. Enter the source IP address.
6. Select the **Read Only** access.
7. Click **Finished**.

7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

  - To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

    If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.

9. Optional: In the **Notes** text box, add a note if necessary.
10. Click **Submit**.

Send flow records from F5 to VCF Operations for networks

**Note:**
To send sFLow data to VCF Operations for networks, you must follow the recommendations mentioned in https://support.f5.com/csp/article/K15193.

VCF Operations for networks supports the following features of F5 BIG-IP:

- Neighbor Discovery (LLDP)
- VLAN
- STP (Spanning Tree Protocol ). This feature is supported only in network assurance and verification.
- Layer 3 Routing (IPv4)
- Route Domain
- Virtual Server
- Load Balance Pool
- NAT (Network Address Translation). This feature is supported only in network assurance and verification.
- Partition

**Add VMware Avi Load Balancer**
If you are an enterprise license user, you can add Avi Load Balancer as a data source in VCF Operations for networks.

- You must verify the following information:
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You must have access to Avi Load Balancer APIs.
- You must you must have at least **Read** access to the following groups and resources:

| Group | Resource |
|---|---|
| Application | • Virtual Service<br>• Pool<br>• Pool Group |
| Operations | • Alert Config<br>• Alert |
| Infrastructure | • Cloud<br>• Service Engine<br>• Service Engine Group<br>• Virtual Routing Framework (VRF) Context |
| Administration | • System Settings<br>• Controller |
| Accounts | • Users<br>• Roles<br>• Tenant |
| Profiles | Analytics Profiles |

In Avi Load Balancer, the authorization of a user account is decided based the combination of roles and tenants. For more information, see the Avi Load Balancer documentation.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under **Load Balancers**, select **Avi Load Balancer**.
4. On the Add a new Avi Load Balancer Account or Source page, provide the following details:

| Option | Action |
|---|---|
| **Collector VM** | Select a collector VM from the drop-down menu. |
| **IP Address/FQDN** | Enter the IP address or the FQDN details of the Avi Load Balancer Cluster or Controller. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |

5. Click **Validate**.
6. Optional: In the **Nickname** text box, enter a nickname.
7. Optional: In the **Tags (Optional)** key-value pair text box, enter a key and a value.

   A key-value pair could be any text. For example, you can use `Layer Access` as key-value pair where `layer` is the `key` and access is the value.

   – To apply the tag in all the associated entities, click the **Apply above tag operations to all associated entities** check box. When you select this option, the tag gets applied to all associated entities. For more details about the associated entities, see Working with Local Tags.

     If you clear the **Apply above tag operations to all associated entities** check box, the assigned tag is removed from all the associated entities.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

After adding the data source, it takes some time to display the Avi Load Balancer details such as the integration with NSX.

To perform a search on Avi Load Balancer entities, use the query string `NSX-ALB Data Source`.

VCF Operations for networks supports the following features of Avi Load Balancer:

- Cluster
- Controller
- Tenant
- Cloud
- Service Engine
- Service Engine Group
- Virtual Service
- Pool
- Pool Member
- Pool Group
- Analytics Profile
- VRF (Virtual routing and forwarding)
- Alert

## Supported CMDBs

VCF Operations for networks supports addition of CMDBs like ServiceNow.

## CMDB Concepts

Basically, a CMDB consists of:

- Configuration item: An entity or a component in a system. Example, a computer, a switch, a service, an application, a server, or a VM.
- Relationship: a link or a type of communication between configuration items. Example: depends on, runs on, exchanges data.

Each configuration item has a defined schema.

- Configuration Item Class: Each configuration item must be associated with a class, which defines its properties.
- Relationship class: Defines the type of relation between configuration items.

You can extend both the classes to add additional properties or customize the properties.

ServiceNow supports application service, which is a set of interconnected applications and hosts that offer a service. ServiceNow allows you to create an application service manually, by using an API, or can automatically discover by Service Mapping. All these applications are stored in ServiceNow CMDB.

When you add a ServiceNow datasource into VCF Operations for networks, VCF Operations for networks fetches the configurations items and the relationships from the ServiceNow CMDB configuration file.

VCF Operations for networks fetches data in regular intervals, by default.

- The complete data fetch happens every 12 hours, which fetches all the records of the classes defined the CMDB configuration. Also, the complete fetch happens when you add or update the datasource.
- The delta fetch happens every 2 minutes, which fetches all new, modified, and deleted records of the classes defined in the CMDB configuration. Approximately, VCF Operations for networks takes around 12 minutes to reflect these details on the user interface.

VCF Operations for networks fetches the class hierarchy and the relationship types during complete fetch only.

Default values for Limitations

| Limit Name | Description | Default Value | Impact for Exceeding the Limit |
|---|---|---|---|
| `maxAppsPerDataSource` | Maximum applications per datasource. | 5000 | The data source stops fetching data with an error on datasource and alerts page and the applications are not updated. |
| `maxTiersPerApp` | Maximum tiers that can be stored per application. | 150 | The applications are not updated until number of tiers are reduced to fit in limit. |
| `maxMembersPerApp` | Maximum members that can be stored per application. | 5000 | The applications are not updated until number of members are reduced to fit in limit. |
| `maxGraphTraversalStackSize` | Maximum size of stack used in graph traversal. | 10000 | The application will not get created and throws `SizeLimitExceededException`. |
| `maxResponseAppCount` | Maximum apps that can be returned in API response. | 5000 | Only the number of applications that fits the limit are returned and UI shows error. |

### Add a ServiceNow Account

You can add ServiceNow as a data source in VCF Operations for networks and fetch your application and tier details. The ServiceNow Configuration Management Database (CMDB) provides you with full visibility of software and hardware infrastructure and the relation between them in your data center. This visibility helps you in managing your inventory.

- You must verify the following information:
  - The data source and its version is supported in VCF Operations for networks. For more information, see Supported Products and Versions.
  - The data source follows VMware Ports and Protocols supported in VCF Operations for networks. For more information, see VMware Ports and Protocols.
- You must have one of the following privileges to your role:

- **Read only admin role** for all the privileges
- **Read only itil role** for the minimum necessary privileges
- Access to the following tables/APIs:

| APIs | Table | Permission Type |
|---|---|---|
| /stats.do | -- | Required |
| /api/now/v1/cimodel/cmdb_ci/fullclasshierarchy | -- | Required |
| /api/now/v2/table/cmdb_rel_type | cmdb_rel_type | Required |
| /api/now/v2/table/cmdb_ci | cmdb_ci | Required |
| /api/now/v2/table/cmdb_ci_service_discovered | cmdb_ci_service_discovered | Required |
| /api/now/v2/table/cmdb_rel_ci | cmdb_rel_ci | Required |
| /api/now/v2/table/cmdb_ci_translation_rule | cmdb_ci_translation_rule | Required |
| /api/now/v2/table/cmdb_ci_cluster_node | cmdb_ci_cluster_node | Required |
| /api/now/v2/table/cmdb_ci_vm_instance | cmdb_ci_vm_instance | Required |
| /api/now/v2/table/cmdb_ci_cluster | cmdb_ci_cluster | Required |
| /api/now/v2/table/cmdb_ci_lb_service | cmdb_ci_lb_service | Required |
| /api/now/v2/table/cmdb_ci_vmware_instance | cmdb_ci_vmware_instance | Required |
| /api/now/v2/table/cmdb_ci_network_adapter | cmdb_ci_network_adapter | Required |
| /api/now/v2/table/cmdb_ci_appl | cmdb_ci_appl | Required |
| /api/now/v2/table/cmdb_ci_spkg | cmdb_ci_spkg | Required |
| /api/now/v2/table/cmdb_ci_computer | cmdb_ci_computer | Required |
| /api/now/v2/table/cmdb_ci_database | cmdb_ci_database | Required |
| /api/now/v2/table/cmdb_ci_qualifier_manual_connection | cmdb_ci_qualifier_manual_connection | Required |
| /api/now/v2/table/cmdb_ci_endpoint | cmdb_ci_endpoint | Required |
| /api/now/v2/table/sys_audit_delete | sys_audit_delete | Optional |
| /api/now/v2/table/sys_user | sys_user | Optional |
| /api/now/v2/table/sys_properties | sys_properties | Optional |

**Note:**
If you do not have access to tables/APIs marked as **Optional**, then VCF Operations for networks runs the application discovery at every 12 hours. And if you have access to tables/APIs marked as **Optional**, VCF Operations for networks runs application discovery at every 30 minutes.

With ServiceNow integration, VCF Operations for networks can discover applications available in ServiceNow CMDB to enable you to directly add them into VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click **Add Source**.
3. Under CMDBs, select **ServiceNow**.
4. On the Add a new ServiceNow Account or Source page, provide the following details:

| Option | Action |
|---|---|
| **Collector (Proxy) VM** | Select a collector VM from the drop-down menu. |

| Option | Action |
|---|---|
| **IP Address/FQDN** | Enter the IP address or the FQDN details. |
| **Username** | Enter the user name. |
| **Password** | Enter the password. |
| **Web Proxy (Optional)** | Select a web proxy from the drop-down menu.<br>**Note:**<br>The **Web Proxy (Optional)** is visible only if you have configured a web proxy in VCF Operations for networks. |

5. Click **Validate**.
6. To add a customized CMDB configuration, do the following:
   a) Select **Customize CMDB configuration**.
   b) Click **download** to download the default configuration file.
   c) Update the file properties. See, Customizing the CMDB Configuration.
   d) On the Add Data Source page, browse to select the updated JSON file.

   **Note:**
   If you add customize CMDB configuration, then VCF Operations for networks validates all the newly added entries for **Required** privileges.
7. Optional: In the **Nickname** text box, enter a nickname.
8. Optional: In the **Notes** text box, add a note if necessary.
9. Click **Submit**.

After you add a ServiceNow data source, VCF Operations for networks discovers the applications available in the ServiceNow CMDB, which you add into VCF Operations for networks. For more information, see Discover Applications.

Default CMDB Configuration File

VCF Operations for networks supports ServiceNow customizations using the configuration file in the JSON format.

```
{
  "fetchOnlyApprovedApplications": false,

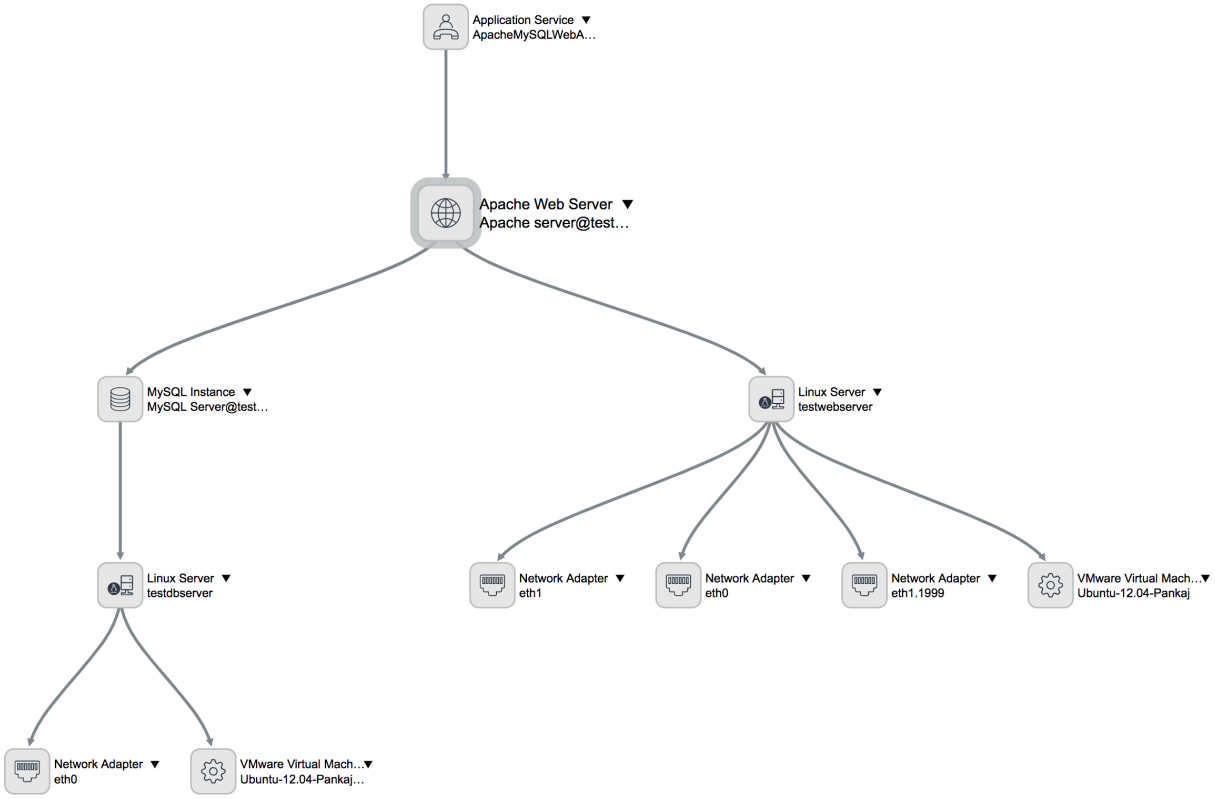
    ]
  }
```

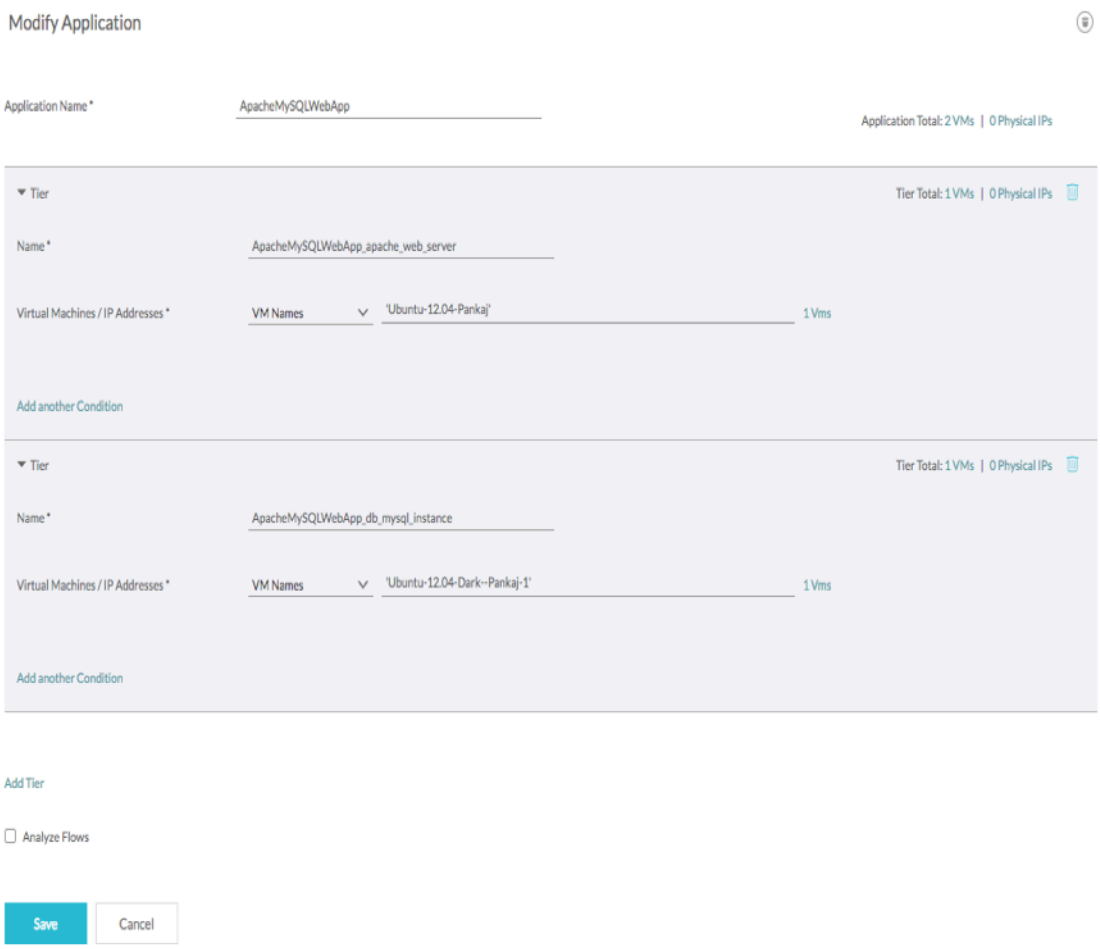
VCF Operations for networks When the configuration change occurs, might take 30 minutes for full data fetch and for recomputation of all applications.

**An example of a ServiceMap and discovered application using default CMDB configuration**

**The updated page on VCF Operations for networks for adding an application**

Using a default CMBU configuration enables VCF Operations for networks to discover the applications in ServiceNow.





## Customizing the CMDB Configuration

To support various customizations, the ServiceNow and VCF Operations for networks integration supports a generic configuration. The CMDB configuration must be in the JSON format.

The configuration includes:

- the configuration items
- the relation between the configuration items
- the rules for the dependency graph traversal.

You can customize the CMDB configuration based on your implementations.

**Note:**
When you change the configuration, a complete fetch happens and all the applications are recomputed. So, this process might take at least 30 minutes to appear on the Discovered Application Dashboard.

| Field Name | Description |
|---|---|
| `fetchOnlyApprovedApplications` | Allows the boolean value to fetch only approved applications from ServiceNow. By default, the value is set to `False`. |
| `nameBasedSearchForVm` | Allows the boolean value to indicate whether to create a custom VM search criteria with the VM name if the ServiceNow VM is not present in VCF Operations for networks. If the value is set to `True`, then a custom VM name criteria is created and count will be reflected when corresponding VM is detected in VCF Operations for networks without recomputing the application. This can be used when you create the dependency graphs or the service map manually, without using Service Mapping. By default, the value is set to `False`. |
| `ignoreWorkloadCheck` | Allows a boolean value to indicate whether to add an entity to the tier even when an associated workload entity does not exist. This can be used when you create the dependency graphs or the service map manually, without using Service Mapping and when relationships are not defined till the workload layer. By default, the value is set to `False`. |
| `ciGroup` | Defines configuration items and relationships to fetch from ServiceNow. This field allows the following properties:<br>• `Name`: Name for the configuration item group<br>• `Value`: List of ServiceNow class names that are part of this group.<br>• `ValueType`: Allows `CI_CLASS` (the class name to fetch) and `CI_VALUE`.<br>— `CI_CLASS` - to fetch the class.<br>— `CI_VALUE`<br>**Note:**<br>VCF Operations for networks always fetches `applicationClasses`, `workloadCIClasses`, `trackedCIClasses`, `workloadCIClasses`, and `relationClasses`.<br>• `systemGenerated`: Allows the boolean value to indicate whether the class is a user-defined class or a default class.<br>• `expandCIClass` - Allows the boolean field to indicate whether to fetch the subclasses of the configuration item class listed in `Value`. |

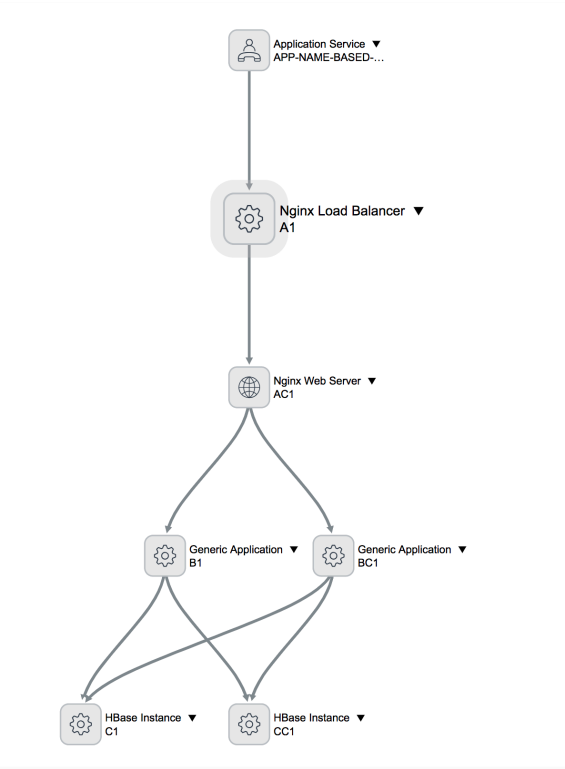
| Field Name | Description |
|---|---|
| `Rules for graph traversal` | Supports three types of traversal rules:<br>• `traversalRule`: All allowed or valid traversals.<br>• `traversalStopRule`: Traversals that are not allowed.<br>**Note:**<br>The rules in `traversalStopRule` have higher priority than the rules in `traversalRule`.<br>• `associationRule`: Traversals that are allowed for the associated workload with entity.<br>Properties of a rule:<br>• `fromNode`: List of `ciGroup` that are the source of the traversal.<br>• `toNode`: List of `ciGroup` that are the destination of traversal.<br>• `relationship`: List of `ciGroup` that have a relationship in a type of traversal.<br>• `priority`: If a `ciGroup` matches two rules, then the rule for the `ciGroup` is set based on the `priority`. Greater the priority number higher the priority value. |
| `applicationClasses` | Lists all entry point configuration item classes for the graph traversal. These classes represent the configuration item types which are used as application classes in the CMDB.<br>The default configuration uses `cmdb_ci_service_discovered` class. This class represents applications created by the ServiceMapping feature of ServiceNow. |
| `workloadCIClasses` | Lists all the configuration items that host either a software-based service or an operating system like Linux Server, Windows Server. Example, VMs, AWS instances, Physical Servers.<br>Typically, workload configuration items are placed towards the end of the dependency graph. Tiers are not created for the configuration item classes that are mentioned in this group.<br>The default configuration contains the following configuration item classes:<br>• `cmdb_ci_computer`: Represents all compute related configuration items. This is a super class for all Linux and Windows Servers.<br>• `cmdb_ci_vm_instance`: Represents virtual compute entities like VMs and AWS instances.<br>• `cmdb_ci_vmware_instance`: Represents VMware VMs. |
| `trackedCIClasses` | Lists all configuration items that can be part of the dependency graphs, but are not `applicationClass` or `workloadCIClass`. The configuration items in this group are required for the graph to complete from `applicationClasses` to `workloadCIClasses`. VCF Operations for networks creates tiers for all the classes mentioned in `trackedCIClasses`, unless the class is mentioned under `ignoredTierCiClasses`. |
| `relationshipTypeClasses` | Lists all related configuration items represented by relation configuration items classes or relation types.<br>The default configuration uses * to fetch all relation types. |
| `workloadRelationshipTypeClasses`: | lists relation types which typically represent the relations with workload entities. Following are the relations supported by default in ServiceNow:<br>• `Hosted on::Hosts`<br>• `Instantiates::Instantiated by`<br>• `Runs on::Runs`<br>• `Virtualized by::Virtualizes` |

| Field Name | Description |
|---|---|
| `ignoredCiClasses` | Lists all the configuration items that VCF Operations for networks must ignore to fetch from ServiceNow CMDB.<br>This is useful while fetching a super class, to ignore the unnecessary subclasses.<br>By default, `cmdb_ci_vcenter_server_obj` is listed under `ignoredCiClasses` as vCenter are not required for the application discovery. |
| `ignoredTierCiClasses` | Lists all the configuration items for which tiers must not be created. |

An Example of Discovering Applications Without Workload Relations

Here is a customized CMDB configuration file in which `nameBasedSearchForVm` is defined to discover the applications, where `cmdb_ci_service_discovered` class is the entry point and the workload relations are not defined.

## Topology



## Customized CMDB Configuration File

```
{
  "fetchOnlyApprovedApplications": false,
  "nameBasedSearchForVm": true,
  "ignoreWorkloadCheck": true,
  "ciGroup": [
    {
      "name": "applicationClasses",
      "value": [
        "cmdb_ci_service_discovered"
      ],
      "valueType": "CI_CLASS",
      "systemGenerated": true,
```

```
      "expandCIClass": true
    },
    {
      "name": "relationshipTypeClasses",
      "value": [
        "*"
      ],
      "valueType": "CI_VALUE",
      "systemGenerated": true,
      "expandCIClass": false
    },
    {
      "name": "workloadRelationshipTypeClasses",
      "value": [
        "Hosted on::Hosts",
        "Instantiates::Instantiated by",
        "Runs on::Runs",
        "Virtualized by::Virtualizes"
      ],
      "valueType": "CI_VALUE",
      "systemGenerated": true,
      "expandCIClass": false
    },
    {
      "name": "workloadCIClasses",
      "value": [
        "cmdb_ci_computer",
        "cmdb_ci_vm_instance",
        "cmdb_ci_vmware_instance"
      ],
      "valueType": "CI_CLASS",
      "systemGenerated": true,
      "expandCIClass": true
    },
    {
      "name": "relationClasses",
      "value": [
        "cmdb_rel_ci"
      ],
      "valueType": "CI_CLASS",
      "systemGenerated": true,
      "expandCIClass": true
    },
    {
      "name": "ignoredCIClasses",
      "value": [
        "cmdb_ci_vcenter_server_obj"

        "workloadCIClasses"
      ],
      "relationship": [
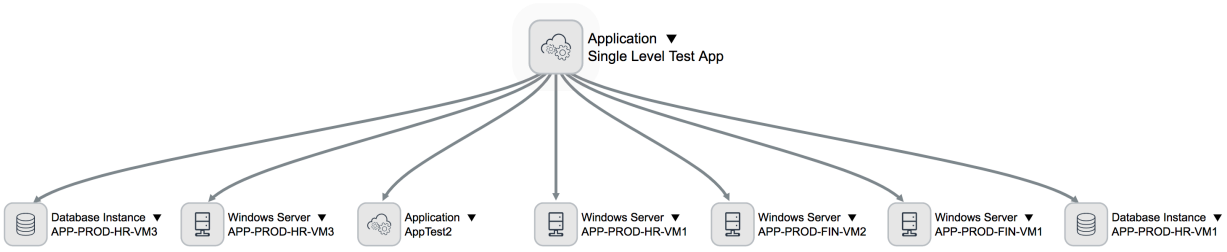
        "workloadRelationshipTypeClasses"
      ],
      "priority": 5
    }
  ]
}
```

An Example of Discovering Single Level Applications

Here is a customized CMDB configuration file in which `nameBasedSearchForVm` is defined to discover the single level applications, where `cmdb_ci_service_discovered` class is the entry point and the workload relations are not defined.

## Topology



## Customized CMDB Configuration File

```
{
  "fetchOnlyApprovedApplications": false,
  "nameBasedSearchForVm": true,
  "ignoreWorkloadCheck": true,
  "ciGroup": [
    {
      "name": "applicationClasses",
      "value": [
        "cmdb_ci_appl"
      ],
```

```
      "valueType": "CI_CLASS",
      "systemGenerated": true,
      "expandCIClass": false
    },
    {
      "name": "relationshipTypeClasses",
      "value": [
        "*"
      ],
      "valueType": "CI_VALUE",
      "systemGenerated": true,
      "expandCIClass": false
    },
    {
      "name": "workloadRelationshipTypeClasses",
      "value": [
        "Hosted on::Hosts",
        "Instantiates::Instantiated by",
        "Runs on::Runs",
        "Virtualized by::Virtualizes"
      ],
      "valueType": "CI_VALUE",
      "systemGenerated": true,
      "expandCIClass": false
    },
    {
      "name": "workloadCIClasses",
      "value": [
        "cmdb_ci_computer",
        "cmdb_ci_vm_instance",
        "cmdb_ci_vmware_instance"
      ],
      "valueType": "CI_CLASS",
      "systemGenerated": true,
      "expandCIClass": true
    },
    {
      "name": "relationClasses",
      "value": [
        "cmdb_rel_ci"
      ],
      "valueType": "CI_CLASS",
      "systemGenerated": true,
      "expandCIClass": true
    },
    {
      "name": "ignoredCIClasses",

```

### FAQs on Add ServiceNow as a Data Source

You find all the common frequently asked questions related to adding ServiceNow as a data source in this topic.

#### How to Assign Privileges to a Role in ServiceNow for adding in VCF Operations for networks?

1. Create a Role in ServiceNow UI.
2. Click **System Administrator** > **Elevate Roles** > **security_admin** > **OK**.
3. Go to **Access Control (ACL)**, and click **New**.
4. For API access, do the following:

| Option | Action |
|---|---|
| **Type** | Select **REST_Endpoint** from the drop-down menu. |
| **Operation** | Select **execute** from the drop-down menu. |
| **Name** | From the drop-down menu select the API entry that you want to add. For list of APIs, see Add a ServiceNow Account topic. |

5. For tables, do the following:

| Option | Action |
|---|---|
| **Type** | Select **record** from the drop-down menu. |
| **Operation** | Select **read** from the drop-down menu. |
| **Name** | From the first drop-down menu, select the table entry that you want to add. From the second drop-down menu, select **None**. For list of tables, see Add a ServiceNow Account topic. |

6. In the **Requires role** table, select the role you want to add the access control.
7. Click **Submit**.

**Do I need to Add all the APIs/Tables Mentioned in the Add a ServiceNow Account Topic?**

To run application discovery every 30 minutes, you must provide all the required privileges. However, if you have access to the following table, you can add the data source in VCF Operations for networks and **VALIDATE**:

| APIs | Table | Permission Type |
|---|---|---|
| /stats.do | -- | Required |
| /api/now/v1/cimodel/cmdb_ci/fullclasshierarchy | -- | Required |
| /api/now/v2/table/cmdb_rel_type | cmdb_rel_type | Required |
| /api/now/v2/table/cmdb_ci | cmdb_ci | Required |
| /api/now/v2/table/cmdb_ci_service_discovered | cmdb_ci_service_discovered | Required |
| /api/now/v2/table/cmdb_rel_ci | cmdb_rel_ci | Required |

VCF Operations for networks validates the required privileges and shows any missing privileges as an error. You can check the missing privileges, and then get access to the missing privileges and **VALIDATE** again.

**Not able to find `/api/now/v1/cimodel/cmdb_ci/fullclasshierarchy` in ServiceNow Access Control (ACL), How to add the API in ServiceNow ACL?**

1. Create a Role in ServiceNow UI.
2. Click **System Administrator** > **Elevate Roles** > **Security Admin** > **OK**.
3. Go to **Access Control (ACL)**, and click **New**.
4. For API access, do the following:

| Option | Action |
|---|---|
| **Type** | Select **REST_Endpoint** from the drop-down menu. |
| **Operation** | Select **execute** from the drop-down menu. |
| **Name** | In the first drop-down menu enter `CMBD Model API Read`. From the second drop-down menu, select **None**. |

5. In the **Requires role** table, select the role you want to add the access control.
6. Click **Submit**.

**How to make any role read-only in ServiceNow?**

To make a role read-only, you must assign **snc_read_only** to the role. For details, see Read-only role topic in ServiceNow Documentation.

**I have all the necessary privileges, still I am getting `Missing privileges` message, what to do?**

In some of the tables you must add another ACL with the same table to provide access to all the attributes by selecting `*` form the second **Name** drop-down menu. Also, ensure you have both the ACLs in the system to get the necessary privileges.

## Bulk Add Devices as Data Sources

You can bulk upload network devices, such as routers, switches, load balancers, and firewalls in VCF Operations for networks and add those uploaded devices as data sources.

To add multiple network devices at once, you need to add the necessary information related to the network devices in a CSV file and upload the file in VCF Operations for networks.

Download the sample `.csv` file from VCF Operations for networks and add the details mentioned in the `.csv` file. The sample `.csv` file contains all the fields that you need to use to bulk upload your network devices, along with examples for each field.

The `.CSV` file must have information in the following fields:

**Table 1307: CSV Fields**

| Field Name | Description | Importance |
|---|---|---|
| **datasource_type** | The type or category of the data source.<br>**Note:**<br>See the sample `.csv` for accepted values. | Mandatory |
| **ip** | IP address of the data source.<br>You need to add either IP address or FQDN. | Mandatory |
| **fqdn** | FQDN of the data source.<br>You need to add either IP address or FQDN. | Mandatory |
| **usersname** | User name of the device. | Mandatory |
| **password** | Password of the device. | Mandatory |
| **nickname** | Any nick name that you want to give to the device. | Mandatory |
| **notes** | Any additional info that you want to add as a note. | Optional |
| **snmp_version** | SNMP version that you want to use.<br>Valid entries are v2c, v3. | Optional |
| **snmp_community_string** | SNMP v2 community string.<br>If you use SNMP Version as v2c, **snmp_community_string** is a mandatory field. | Optional |
| **snmp_username** | SNMP user name.<br>If you use SNMP version as v3, **snmp_username** is a mandatory field. | Optional |
| **snmp_context_name** | Context name for the SNMP. | Optional |
| **snmp_auth_type** | SNMP Authentication Type.<br>You can leave this field blank if SNMP Authentication Type is not available.<br>Valid entries are MD5, SHA. | Optional |
| **snmp_auth_password** | SNMP Authentication Password.<br>If you use SNMP Version as v3 and authentication type is MD5 or SHA, **snmp_auth_password** is a mandatory field. | Optional |
| **snmp_privacy_type** | SNMP Privacy Type.<br>You can leave this field blank if SNMP privacy type is not available.<br>Valid entries are DES, 3DES, AES128, AES192, or AES256. | Optional |
| **snmp_privacy_password** | SNMP Privacy password. Required only if SNMP Version is v3 and privacy type is present. | Optional |
| **polling_interval_in_mins** | Polling interval details in minutes. | Mandatory |
| **collector_ip** | IP address of the collector that you want to use for the device. | Mandatory |

To bulk add the network devices, do the following steps:

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. In the **Data Source** tab, from the drop-down menu located in the top-right corner, select **Bulk add devices**.
3. In the **Add physical devices in bulk from file** page, click download sample file.

   **Note:**

   You must update all the required field in the `.CSV` file.
4. Click **Browse** and upload the `.CSV` file that has all the details related to the network devices you want to add as data sources.
5. Click **Upload & Add** button.

   If there are any issues in the `.CSV` file, you see all the relevant error listed in a table format. You can also export the errors as a `.CSV` file.

   Correct all the issues and upload the `.CSV` file again to add your devices as data sources.

## Working with Network Discovery

When you have several network devices in your data center, discovering them and adding them manually to VCF Operations for networks as data sources might be time-consuming and inefficient.

VCF Operations for networks automatically discovers the network devices in your data center and provides the options to add these discovered devices as data sources or export their details.

### Discover Network Devices Using Network Auto Discovery

You can discover network devices such as routers, switches, firewalls, and F5 load balancer within your network. Once you have discovered these devices in your network, you can then add them to VCF Operations for networks to get deeper visibility into them.

**Discover Network Devices in VCF Operations for networks**
You can discover supported routers, switches, firewalls, and F5 Load Balancer.

You must verify the network devices supported in VCF Operations for networks. For more information, see Supported Products and Versions.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click the **Device Auto Discovery** tab and select **Discovery Profiles**.
3. To create a new discovery profile, click **Create Discovery Profile**.
4. Define the scope based on which you want to discover the devices. You can discover devices either using the seed IP or the IP range.
   1. To discover devices based on seed IP, from the **Discovery Method** drop-down, select **Seed IP**.
      Here, the devices are recursively discovered using the CDP and LLDP protocols up to the discovery depth that you define.
   2. To discover devices based on the IP range, from the **Discovery Method** drop-down, select **Scan IP Range**.
      The scan IP Range defines the range of IP addresses where network discovery starts a scan.

      **Note:**
      Network auto discovery supports only a maximum of 4096 IP addresses per collector.

   While adding the IP addresses, you can perform the following actions:

   - To add a single IP address, specify the IP address.
   - To add multiple IP addresses, use commas.
   - To add an IP range, specify the IP entries with the **-** or **/** range separator.
   - To add an IP range and exclude few IP addresses, click **Add Exceptions**, enter the exception IPs.

5. Provide appropriate access credentials and click **Next**. Supported access credential types are SSH, SNMP v2, SNMPv3, and APIs.

   To discover F5 Big-IP Load Balancer devices, you must enter your API credentials.

6. Provide a name for saving your discovery profile and set the discovery job schedule.

   1. You can schedule discovery jobs to:
      – Run once at the specified date and time.
      – Or, run periodically such as daily, weekly, monthly, or at your defined custom intervals.
   2. Provide a name for saving your discovery profile.

7. Click **Submit**.

You can bulk add the discovered network devices as data sources to VCF Operations for networks. See Bulk Add Discovered Devices as Data Sources for more information.

**Bulk Add Discovered Devices as Data Sources**
You can bulk add the discovered devices as data sources in VCF Operations for networks.

1. From the left navigation pane, go to **Settings** > **Accounts and Data Sources**.
2. Click the **Device Auto Discovery** tab and select **Discovered Devices**.

   The discovered devices are divided in the following tabs:

   - **All**: Displays all the discovered devices.
   - **Ready to Add**: Displays all the devices that are ready to be added as data sources.
   - **Needs Attention**: Displays the devices that have one or more problems and need remediation.
   - **Excluded**: Displays the devices which cannot be added as data sources. You can also select devices from any of the other tabs and add it to the excluded list. These devices can later be removed from the excluded list and added as data sources.

3. Select one or more devices from the **All** or **Ready to Add** tab and click the **Add As Source** button.
4. To bulk edit information of the devices before adding them as data sources, select the devices, click the three dots icon next to **Add As Source** and click **Bulk Edit and Add**.

   You can edit the following fields.

   - **Collector VM**: From the drop-down, select:
     – **No Change** to retain your existing collector.
     – Or, **Override existing values** to enter a new values.
   - **Autoinferred Device Name**: From the drop-down, select:
     – **No Change** to retain your existing device name.
     – **Append to existing values** to enter new values at the end of the existing values.
     – Or, **Prepend to existing values** to enter new values at the beginning of the existing values.
   - **Access Credentials**: From the drop-down, select:
     – **No Change** to retain your existing credentials.
     – Or, **Override existing values** to provide a new credentials that works across all the data sources.
   - **Config Polling Intervals**: From the drop-down, select:
     – **No Change** to retain the previously configured polling interval.
     – Or, **Override existing values** to provide a new polling interval for the VCF Operations for networks platform to collect the configuration data from the selected data sources
   - **SNMP**: From the drop-down, select:
     – **No Change** to retain your existing SNMP credentials.
     – Or, **Override existing values** to enter a new values.
   - **Notes**: From the drop-down, select:
     – **No Change** to retain your existing notes.
     – Or, **Override existing values** to enter a new note.

   Click **Next**.

In the next screen, review the devices and add them as data sources.

Bulk operations may take some time to complete. If the bulk add operation is successful, you will see a notification for the same.
If the operation fails for one or more data sources, the details of the devices and the details due to which the operation failed are displayed.

You can fix the errors and retry the operation on the failed devices.

### Discover Network Devices by Running CLI Commands

You can generate and run scripts on the VCF Operations for networks Collector CLI to discover devices in your network automatically and export the details of discovered devices to a `.csv` file.

**Note:**

Discovering network devices by running CLI commands will be deprecated in a future release of VCF Operations for networks.

You can discover the following devices by running the CLI commands:

- Cisco switches
- Arista switches
- Juniper switches
- Dell switches
- F5 Big-IP
- Brocade switches
- Palo Alto Networks
- Check Point Firewall
- Cisco ASA

1. Log in to the VCF Operations for networks Collector CLI as a **Support** user.
   Provide your CLI login credentials using the Secure Socket Shell (SSH) client.
2. Switch to a **Ubuntu** user.
   ```
   ub
   ```
3. Run the following command to generate the Python script in your present working directory.
   ```
   java -cp "/home/ubuntu/build-target/common-utils/tools-0.001-SNAPSHOT.jar"
    com.vnera.tools.DiscoveredDevicesTool -w script.py
   ```
   You use this script to perform network discovery.
4. Run the following command to generate the sample credentials file in your present working directory.
   ```
   java -cp "/home/ubuntu/build-target/common-utils/tools-0.001-SNAPSHOT.jar"
    com.vnera.tools.DiscoveredDevicesTool -s sample_creds.csv
   ```
   You use the sample credentials file to access the devices in your network.

   Here is an example of the sample credentials file:

   ```
   "credential_name","connection_type", "username", "password", "snmp_version",
   "community_string", "snmp_user", "snmp_context", "snmp_auth_type", "snmp_auth_password",
   "snmp_privacy_type", "snmp_privacy_password"
   "SSH1","SSH","admin","admin","","","","","","","","","
   "API1","API","admin","admin","","","","","","","","","
   "SNMP1","SNMP","","","v2c","community","","","","","","","
   "SNMP2","SNMP","","","v3","","user","context","authtype","authpass","privacytype","privacypass"
   ```
5. Update the sample credentials file with your SSH, SNMP v2c, SNMPv3, or API credentials.

   You can enter multiple credentials in the file by providing a unique `credential_name` for each entry.

To discover F5 Big-IP load balancers, you must enter your API credentials.

**Note:**
You cannot discover other network devices using your API credentials.

6. Run the `help` command on the Python script to view the options supported by the script.

```
python3 script.py --help
```

You can use these options to authenticate your credentials and perform network discovery.

| Option | Description |
|---|---|
| --host | The IP address of the VCF Operations for networks platform node1. |
| --deployment type | The type of deployment on which you are performing this operation. Accepted values are `onprem` and `saas`.<br>The default value is `onprem`. |
| --username | The user name of the platform user.<br>**Note:**<br>You must always enclose the username in single quotes. |
| --password | The password of the platform user.<br>**Note:**<br>You must always enclose the password in single quotes. |
| --domain_type | The domain type to authenticate user credentials. Accepted values are `LOCAL` and `LDAP`. |
| --domain_value | If the domain type is LDAP, provide your LDAP domain name. |
| --proxy_ips | The IP address of VCF Operations for networks Collector. |
| --credentials_file_path | The location of the credentials file which contains the SSH, SNMP, or API credentials. |
| --network_ranges | The IP address range to perform network discovery on. You can specify the IP addresses in the network range format or the CIDR range format. |
| --seeds | The seed IP addresses or the seed FQDN of network devices to begin the network discovery process.<br>**Note:**<br>When you run the network discovery script, you begin the network discovery process with given seed IP addresses as the starting point.<br>Each seed's neighbor devices are discovered based on industry protocols such as CDP and LLDP. Each discovered device is then used as a seed to recursively discover other devices in your network until all devices in your network are discovered or the seed depth is reached. |

| Option | Description |
|---|---|
| --seed_depth | The depth of discovering network devices.<br>**Note:**<br>The seed depth indicates how many levels of neighbors must be explored from the seed IP address. By default, the depth of the seed is 0; the depth of the seed's neighbors is 1; the depth of the seed's neighbors' neighbors is 2 and so on.<br>If you enter the seed depth as 2, you can discover devices of the seed, the seed's neighbors, and the seed's neighbor's neighbors. |
| --ignored_list | The list of IP addresses to exclude from network discovery. You can specify the IP addresses in the following formats:<br>• Individual IP address<br>• FQDN<br>• Network range<br>• CIDR range |
| --download_discovered_devices | The option to download the previously discovered devices. Enter `True` or `False`. |
| --out | The name of the CSV output file for successful network discovery. The default name of the output file is `auto_gen_discovered_devices.csv`. |
| --clear_all | The option to erase details of the discovery such as discovery job, credential profile, job result, and discovered devices. Enter `True` or `False`. |
| --wait_time_in_secs | The maximum wait time (in seconds) to discover devices. |

7. Run the Python script with one of the following options:

| Choice | Example |
|---|---|
| **Provide the network range for discovery by using the --network_ranges option.** | `python3 script.py --deployment_type onprem --username 'user' --password 'pwd' --domain_type LOCAL --proxy_ips 10.xx.196.xxx --out discovered_devices.csv --credentials_file_path sample_creds.csv --network_ranges 10.xxx.xx.158/24` |
| **Provide the seed address and the seed depth for network discovery by using --seeds and --seed_depth options.** | `python3 script.py --deployment_type onprem --username 'user' --password 'pwd' --domain_type LDAP --domain_value vmware.com --proxy_ips 10.xx.196.xxx --out discovered_devices.csv --credentials_file_path sample_creds.csv --seeds 10.xxx.xx.xxx --seed_depth 2` |

**Note:**

You must run the Python script with your updated credentials file that includes your SSH, SNMP v2c, SNMPv3, or API credentials.

The python script only discovers devices that are within the reachability scope of the collector network. It does not discover devices that are available on the network, but not accessible from the collector network.

8. Based on the status of the operation, do one of the following:

| Status | Action |
|---|---|
| **The operation succeeds.** | Open the CSV file. An example of the CSV file is as follows: |

| Status | Action |
| --- | --- |
| | "DataSourceType","IP","fqdn","Username","Password","CSPRefres<br>"CentralCliEnabled","IPFixEnabled","SwitchType","ParentvCente<br>"snmp_version","snmp_community_string","snmp_username","snmp_<br>"snmp_auth_type","snmp_privacy_type","ProxyIP"<br>"DataSource1","","Domain_name","username","<pwd>","",<br>"nick_name_discovered_devices_1","","","","","","","","","","<br>"DataSource2","10.1xx.xx.1x","","username","pwd","",<br>"<br>nick_name_discovered_devices_2","","","","","","","","","","<br> |
| **The operation fails or times out.** | Run the Python script with the --clear_all option to clear the details of the discovered devices and start a new network discover operation.<br>For example:<br>`python3 script.py --deployment_type onprem --username 'user' --password 'pwd' --proxy_ips 10.xxx.xxx.xx --clear_all true` |

You can bulk add the discovered network devices as data sources to VCF Operations for networks by using the `operations-for-networks-sdk-python` SDK. See Bulk Add Data Sources Using the Python SDK for more information.

## Editing and Migrating Data Sources

You can edit, migrate, and delete data sources from VCF Operations for networks.

### Bulk Add Data Sources Using the Python SDK

You can bulk add network devices as data sources to VCF Operations for networks by using the `network-insight-sdk-python` SDK.

- You must have access to the VCF Operations for networks platform CLI.
- You must have the CSV file containing the list of network devices in the following format:

```
"DataSourceType","IP","fqdn","Username","Password","CSPRefreshToken","NickName",
"CentralCliEnabled","IPFixEnabled","SwitchType","ParentvCenter","IsVMC",
"snmp_version","snmp_community_string","snmp_username","snmp_password",
"snmp_auth_type","snmp_privacy_type","ProxyIP"
"DataSource1","","Domain_name","username","<pwd>","",
"nick_name_discovered_devices_1","","","","","","","","","","","","10.xx.xxx.xx"
"DataSource2","10.1xx.xx.1x","","username","pwd","",
" nick_name_discovered_devices_2","","","","","","","","","","","","10.xx.xx.xxx"
```

  You can create the file manually, or discover the devices in your network by performing network discovery. See Discover Network Devices by Running CLI Commands for more information.

You can add the following data sources only:

- Cisco switches
- Arista switches
- Juniper switches
- Dell switches
- F5
- Brocade switches
- Palo Alto Networks
- Check Point Firewall
- Cisco ASA

1. Log in to the VCF Operations for networks platform CLI as a **support** user.
2. Switch to a **Ubuntu** user. Run the following command:

   ```
   ub
   ```

3. Navigate to the `/home/ubuntu` directory.

   ```
   cd /home/ubuntu
   ```

4. Download the `network-insight-sdk-python` SDK from GitHub.

   ```
   wget https://github.com/vmware/network-insight-sdk-python/archive/refs/heads/master.zip
   ```

5. Unzip the contents of the SDK and delete the ZIP file.

   ```
   unzip master.zip && rm master.zip
   ```

6. Export the Python path to `/home/ubuntu/network-insight-sdk-python-master/swagger_client-py2.7.egg`.

   ```
   export PYTHONPATH=/home/ubuntu/network-insight-sdk-python-master/swagger_client-py2.7.egg
   ```

7. Navigate to the `examples` directory within the SDK. This folder contains the `datasource_addition.py` script.

   ```
   cd /home/ubuntu/network-insight-sdk-python-master/examples
   ```

8. Run the `datasource_addition.py` script to bulk add network devices to VCF Operations for networks. The supported options are:

| Option | Required | Description |
|---|---|---|
| --deployment_type | Required | The type of deployment on which you are performing the bulk addition operation. Accepted values are `onprem` and `saas`. The default value is `onprem`. |
| --platform_ip | Required | The IP address of the VCF Operations for networks platform node1 where you want to add the devices. |
| --username | Required | The user name of the platform user.<br>**Note:**<br>You must always enclose the username in single quotes. |
| --password | Required | The password of the platform user.<br>**Note:**<br>You must always enclose the password in single quotes. |
| --data_sources_csv | Required | The location of the CSV file which contains the details of the devices. |
| --domain_type | Optional | The domain type to authenticate user credentials. Accepted values are `LOCAL` and `LDAP`. |
| --domain_value | Optional | If the domain type is LDAP, provide your LDAP domain name. |

   Here are a few examples.

   ```
   python datasource_addition.py --deployment_type onprem --platform_ip vrni.example.com --username
    'user@vmware' --password 'mypassword' --data_sources_csv /home/ubuntu/discovered_devices.csv
   python datasource_addition.py --deployment_type onprem --platform_ip vrni.example.com --username
    'user@vmware.com' --password 'mypassword' --domain_type LDAP --domain_value vmware.com --
   data_sources_csv /home/ubuntu/discovered_devices.csv
   ```

You can track the result of the network discovery operation on the CLI. If the bulk addition operation fails for one or more devices, you can rectify the errors and reattempt the operation. See Common Data Source Errors for more information.

View the data sources added to VCF Operations for networks by navigating to the **Settings** > **Accounts and Data Sources** page.

### Bulk Edit Data Sources

In VCF Operations for networks, you can enable, deactivate, edit, or delete multiple data sources at once.

You must have added more than one data source into VCF Operations for networks. For more information, see Adding a Data Source in VCF Operations for networks and Bulk Add Data Sources Using the Python SDK.

1. Go to **Settings** > **Accounts and Data Sources**.
2. In the **Accounts and Data Sources** page, select the data sources on which you want to perform bulk operations.
3. From the **Actions** drop-down menu, select the bulk operation that you want to perform.

   **Note:**
   Bulk operations are asynchronous in nature, which means that when a bulk operation is in progress, updates to the selected data sources are temporarily deactivated till the operation completes.

| Operation | Action |
|---|---|
| Enable | Enables data collection on the selected data sources. |
| Disable | Deactivates data collection on the selected data sources. |
| Edit | Allows you to edit the following options:<br>• **Access Credentials** - Edit only the user name and password of the selected data sources.<br>• **Config polling interval** - Edit the interval to collect configuration data from the data sources.<br>• **Notes** - Add additional information that the user wants to add, limited to 150 characters.<br>In the **Edit Sources** page, update the required parameters and click **Submit**.<br>**Note:** Only the common options across the selected data sources are displayed for bulk update.<br>• From the **Access Credentials** drop-down menu, select:<br>– **No Change** to retain your existing credentials.<br>– Or, **Override existing values** to provide a new user name and password that works across all the data sources. After entering the credentials, click **Validate** to validate your credentials against one of the data sources. A successful validation hints that the credentials are most likely true for all the selected data sources.<br>• From the **Config Polling Interval** drop-down menu, select:<br>– **No Change** to retain the previously configured polling interval.<br>– Or, **Override existing values** to provide a new polling interval for the VCF Operations for networks platform to collect the configuration data from the selected data sources.<br>• From the **Notes** drop-down menu, select:<br>– **No Change** to retain your existing notes.<br>– Or, **Override existing values** to enter a new note. |

| Operation | Action |
|---|---|
| Delete | Deletes the selected data sources from VCF Operations for networks.<br>If the selected data sources have a dependency on one or more data sources, do one of the following actions:<br>• Delete the dependent data sources before deleting the selected data sources.<br>• Or, delete the dependent data sources along with the selected data sources. |

Bulk operations may take some time to complete. After the operation completes, if the operation is successfully, VCF Operations for networks displays a notification indicating that the operation succeeded for all the selected data sources.

If the operation fails for one or more data sources, VCF Operations for networks displays an error notification indicating the status of the operation. Click the **View Details** button to view the following details:

- List of data sources for which the operation succeeded.
- List of data sources for which the operation failed, and the reason for failure.

You can fix the errors and retry the operation on the failed data sources.

### Migrate Data Sources to a Different Collector

If a collector VM is down or deleted, you can add a new collector VM and migrate data source from the old collector VM to the new collector VM.

1. Go to **Settings > Infrastructure and Support > Overview and Updates > Collector VMs** section, click the edit icon next to the collector name in the list.

   If the collector VM is down, you see the error message. The Edit Collector page lists all the data sources added to the collector.
2. To migrate a data source, click **Migrate** for a particular data source.
3. Enter the required information of the new collector on the Edit Account or Source page.

**Table 1308:**

| Fields | Description |
|---|---|
| Collector VM | Name of the new collector VM to which the data source has to be migrated |
| IP Address | Pre-filled IP/FQDN address of data source |
| Username | Username for the data source |
| Password | Password for the data source |

4. Click **Validate** and then click **Submit**.

   The data source is then deleted in the old collector VM and is added to the new collector VM.
5. Once the migration is successful, you will see the new collector VM against the data source in the **Enabled** column in the **Accounts and Data Sources** page.

   **Note:**

   - If you are migrating VMware vCenter to another collector VM, then ensure that you migrate the corresponding NSX Manager also to the same collector VM.
   - When you migrate NSX Manager to another collector VM, the child data providers such as NSX controller and NSX Edge are also migrated to the new collector VM.

### Delete a Data Source from VCF Operations for networks

If you do not want to view data from a data source or a data source is not in use, you can delete the data source from VCF Operations for networks.

> **Note:**
> If any data source is no longer available in your environment, you must delete that data source form VCF Operations for networks.

1. Sign in to the VCF Operations for networks web console.
2. Go to **Settings** > **Accounts and Data Sources**.
3. Click the **Delete Data Source** icon next to the data source you want to delete.
   The VCF Operations for networks prompts you for confirmation.
4. Click **Yes**.

> **Note:**
> After you remove a data source from the system, you can add the same data provider back only after two or more hours.

**Unregister a Customer**
To unregister or delete a customer from VCF Operations for networks, you must first delete all the collectors of that customer and then contact VMware Support to remove that customer from VCF Operations for networks.

## Configuring VCF Operations for networks Settings

You can configure various aspects of VCF Operations for networks from the **Settings** page.

### VCF Operations for Networks System Recommendations and Requirements

For optimum performance, you must match the minimum recommendations for the deployment.

#### Recommendations for the Platform Deployment

**Table 1309: Specifications for Platform Brick Size**

| Brick Size | Cores required for 2.1 GHz CPU | Cores required for 2.3 GHz CPU | Cores required for 2.6 GHz CPU | RAM | Disk |
|---|---|---|---|---|---|
| Small | 5 | 5 | 4 | 16 GB | 1 TB |
| Medium | 10 | 9 | 8 | 32 GB | 1 TB |
| Large | 15 | 14 | 12 | 48 GB | 1 TB |
| Extra Large | 20 | 18 | 16 | 64 GB | 2 TB |
| 2 Extra Large | 30 | 27 | 24 | 128 GB | 3 TB |

> **Note:**
> - The Small brick size has limited functionality and must be used for evaluation purposes only. Do not use this brick size in production environments.
> - The reservation for the CPU speed and RAM for each node must be 100% of the value specified above.
> - If the disk in any of the platform nodes exceeds 95% of the capacity, VCF Operations for networks UI will not be accessible.
> - To match your setup to all the specifications, you might have to add the resources (RAM, Disk, CPU). See Broadcom knowledge base article 53550 and Increase the Brick Size of Your Setup.

**Table 1310: Non-Cluster Deployment - Maximum Capacity**

| Brick Size | *Number of VMs (K = Thousand) | Flows per Day (M = Million) | Total Flows (M = Million) | Flow Planning (M = Million) | Metric Capacity (metric points per day) | Number of Network Rules for Network Map and Intents (K = Thousand) | Number of VMs for Flow Based Application Discovery | Number of UI Entities in the Network Map Topology |
|---|---|---|---|---|---|---|---|---|
| Medium | 4K | 1M | 4M | 2M | 1 | Not Applicable | Not Supported | Not Supported |
| Large | 6K | 2M | 8M | 4M | 1.1 | Not Applicable | Not Supported | Not Supported |
| Extra Large | 10K | 2M | 8M | 4M | 2.5 | 170K | 3K | 5K |
| 2 Extra Large | 15K | 3M | 12M | 4M | 3.9 | 170K | 3K | 5K |

**Note:**

- The Network Verification and Assurance (Network Map and Intents) and Flow Based Application Discovery (Flows) features are available only for Extra Large brick size only.
- * The count of VMs and edges mentioned in the table is the maximum individual limit for a single deployment. So, if you have edges in your setup, you might have to reduce the VM count.
- The count of VMs includes the templates on the VMware vCenter as well.
- Total Flows is the maximum count of flows the system can store for the retention period.
- Flow Planning is the total flows for which the system can perform security planning.

**Table 1311: Cluster Deployment - Maximum Capacity**

K=Thousand

M=Million

| Scenario | Brick Size | Cluster Size | Number of VMs | Flows per Day | Total Flows | Flow Planning | Metric Capacity (metric points per day) | Network Rules for Maps and Intents | Number of VMs for Flow Based Application Discovery | Number of UI Entities in Network Map Topology |
|---|---|---|---|---|---|---|---|---|---|---|
| Scenario 1 | Large | 3 | 10K | 2M | 8M | 4M | 1.7 | Not Applicable | Not Supported | 5K |
| | Extra Large | 3 | 18K | 6M | 24M | 6M | 3.8 | 170K | 3K | 5K |
| | Extra Large | 5 | 30K | 10M | 40M | 10M | 6.3 | 170K | 3K | 5K |
| | Extra Large | 7 | 58K | 12M | 48M | 10M | 8.9 | 170K | 3K | 5K |
| | Extra Large | 10 | 100K | 15M | 60M | 10M | 12.7 | 170K | 3K | 5K |
| | Extra Large | 15 | 150K | 20M | 80M | 10M | 18.7 | 170K | 3K | 5K |
| | 2 Extra Large | 3 | 27K | 9M | 36M | 6M | 5.8 | 170K | 3K | 5K |
| | 2 Extra Large | 5 | 45K | 15M | 60M | 10M | 9.7 | 170K | 3K | 5K |
| | 2 Extra Large | 10 | 150K | 22.5M | 90M | 10M | 19.5 | 170K | 3K | 5K |

| Scenario | Brick Size | Cluster Size | Number of VMs | Flows per Day | Total Flows | Flow Planning | Metric Capacity (metric points per day) | Network Rules for Maps and Intents | Number of VMs for Flow Based Application Discovery | Number of UI Entities in Network Map Topology |
|---|---|---|---|---|---|---|---|---|---|---|
| | 2 Extra Large | 15 | 225K | 30M | 120M | 10M | 29.2 | 170K | 3K | 5K |
| Scenario 2 | Extra Large | 3 | 12K | 3M | 12M | 4M | 3.8 | 2M | 12K | 100K |
| | Extra Large | 5 | 18K | 6M | 24M | 6M | 6.3 | 5M | 24K | 100K |
| | Extra Large | 7 | 30K | 10M | 40M | 10M | 8.9 | 5M | 24K | 100K |
| | Extra Large | 10 | 72K | 13M | 52M | 10M | 12.7 | 5M | 24K | 100K |
| | Extra Large | 15 | 130K | 18M | 72M | 10M | 18.7 | 5M | 24K | 100K |
| | 2 Extra Large | 3 | 18K | 4.5M | 18M | 4M | 5.8 | 2M | 12K | 100K |
| | 2 Extra Large | 5 | 27K | 9M | 36M | 6M | 9.7 | 5M | 24K | 100K |
| | 2 Extra Large | 10 | 108K | 19.5M | 78M | 10M | 19.5 | 5M | 24K | 100K |
| | 2 Extra Large | 15 | 195K | 27M | 108M | 10M | 29.2 | 5M | 24K | 100K |

**Note:**

- Metric capacity is calculated using a 31 day retention period and recommended disk allocation for the brick size. Actual capacity can vary if parameters are adjusted.
- Scenario 1 focuses on VMs and flows while running automated Application Discovery and Network Assurance and Verification features with limited capacity. Scenario 2 is for an environment that needs to run automated Application Discovery and Network Assurance and Verification feature with full capacity.
- The Network Verification and Assurance (Network Map and Intents) and Flow Based Application Discovery (Flows) features are available only for Extra Large brick size only.
- The number of UI entities means the sum of nodes and edges supported in the Network Map topology.
- The number of rules includes all forwarding entries, including layer 3, layer 2, access control, and NAT.
- * The count of VMs and edges mentioned in the table is the maximum individual limit for a single deployment. So, if you have edges in your setup, you might have to reduce the VM count.
- The number of VMs includes the templates on the VMware vCenter as well.
- Cluster size is the total number of nodes in the cluster.
- Total Flows is the count of flows in the system for the retention period.
- The query to determine the Total Flows is `count of flows in last 31 days`, assuming the retention period as 31 days.
- Flow Planning is the total flows for which the system can perform security planning.
- VCF Operations for networks supports maximum 10,000 security groups and 10,000 IPSets for a cluster deployment of 10 XL.
- The following cluster configurations are deprecated:
  - 3 L cluster: users should migrate to a 3XL cluster.
  - 7 XL cluster: both scenario 1 and 2 are not supported.
  - 15 XL cluster: users should migrate to a 15 XXL cluster.

## Recommendation for the Collector Deployment

**Table 1312: Specifications for Collector Brick Size**

| Brick Size | Cores required for 2.1 GHz CPU | Cores required for 2.3 GHz CPU | Cores required for 2.6 GHz CPU | RAM | Disk |
|---|---|---|---|---|---|
| Small | 2 | 2 | 2 | 6 GB | 250 GB |
| Medium | 5 | 5 | 4 | 12 GB | 250 GB |
| Large | 10 | 9 | 8 | 16 GB | 250 GB |
| Extra Large | 10 | 9 | 8 | 24 GB | 250 GB |
| 2X Large | 20 | 18 | 16 | 48 GB | 350 GB |

**Note:**

The reservation for the CPU speed and RAM for each node must be 100% of the value specified above.

**Table 1313: Collector Deployment - Maximum Capacity**

| Collector Size | Number of VMs (K = Thousand) | Flows per Day (M = Million) | Flow count in 4 days (M = Million) | Number of Edges for VMware SD-WAN (K = Thousand) |
|---|---|---|---|---|
| Medium | 4K | 2.5M | 3.25M | 4K |
| Large | 10K | 5M | 6.5M | 6K |
| Extra Large | 35K | 10M | 13M | 10K |
| 2X Large | 45K | 17M | 22M | 10K |

**Note:**

- The count of VMs and edges that are mentioned in the table is the maximum individual limit for a single deployment. So, if you have edges in your setup, you might have to reduce the VM count.
- The count of VMs includes the templates on the VMware vCenter as well.
- For a single deployment with more than one collector, the limitation on the total flows across collectors is based on the capacity of the platform.

## Other Requirements and Considerations

- While editing a data source collector, other data source fields cannot be edited.
- During a fresh installation or upgrade to VCF Operations for networks in VCF 9, the support password will be equivalent to the root password. To modify the root password, log in to the appliance through SSH using the support user credentials, elevate to root using the `sudo su` command, and then update the root file using the `passwd` command.
- The network verification and assurance and flow based application discovery features are available for deployments using the Extra Large brick size.
- The maximum time skew between the platform nodes has to be lesser than 30 seconds.
- The availability of the NTP service is critical to system operations. Ensure that you do not reboot the platform node or the collector node when the NTP service is not available.
- When the existing compute resources are completely used by the other processes on the platform, VCF Operations for networks crashes and does not recover automatically. If the services fail to recover, reboot the platform node.
- If the network latency between platform node and upgrade server is greater than 500ms, the VCF Operations for networks upgrade might encounter an error. So, the network latency must be less than 500ms.
- The recommended network latency between platform VMs for optimal performance is up to 3ms. The system performance might degrade beyond the limit.
- The recommended network latency between platform and collector VMs for optimal performance is up to 150ms. The system performance might degrade beyond this limit.

- The recommended disk latency for optimal performance is up to 5ms. If the disk latency is greater than 5ms, the system performance degrades.
- The recommended disk IOPS is 7500.
- For optimum performance, the recommended bandwidth usage between the collector and the platform is 15 Megabytes per second (MBps) or 120 Megabits per second (Mbps).

  **Note:**

  These bandwidth recommendations are made considering the largest collector and the largest platform brick sizes mentioned in this topic.
- For Network Map, the maximum supported firewall rules per VMware NSXManager (including of DFW and edge rules) is 5000.
- To use the Assurance and Verification feature in VCF Operations for networks, you must enable Link Layer Discovery Protocol (LLDP) and Cisco Discovery Protocol (CDP) (if supported) on the network devices.
- As IPv6 addresses occupy more space in memory and disk, enabling IPv6 flow processing can reduce the platform and the collector capacity by up to 20%.

### Supported TLS Versions

VCF Operations for networks supports Transport Layer Security (TLS) versions 1.2 and 1.3.

### Supported Web Browser

- Google Chrome: The latest two versions.
- Mozilla Firefox: The latest two versions.

### Recommendations to Support High Availability

You can customize vSphere HA options to enable vSphere high availability.

- **Host Failure** - Restart VMs
- **Host Isolation**- Deactivated
- **Guest not heartbeating**- Deactivated

## Increase the Brick Size of Your Setup

To match your requirements, you can change the brick size of your appliance from `MEDIUM` to `LARGE` or `LARGE` to `EXTRA-LARGE`.

To increase the brick size of your setup, do the following as necessary:

- Increase the disk size. For more information, see the Increase the Disk Size topic.
- Increase RAM, total vCPU and corresponding reservation. To increase RAM, total vCPU and corresponding reservation, do the following steps that are relevant to your setup:

| Option | Description |
|---|---|
| **For a single node platform or fresh independent OVA** | 1. Log in to VMware vCenter.<br>2. Shutdown the Platform VM using the **Shut Down Guest OS** option.<br>**Note:**<br>Do not use the **Power Off** option.<br>3. Increase RAM, total vCPU and corresponding reservation of the VM as required to match the target brick size.<br>4. **Power On** the Platform VM. |
| **For a cluster setup** | 1. Log in to VMware vCenter.<br>2. Shutdown the Platform VM using the **Shut Down Guest OS** option in the reverse chronological order. For example: Shut down from Node 3 to Node 1. |

| Option | Description |
| --- | --- |
| | **Note:**<br>Do not use the **Power Off** option.<br>After you shut down each Platform node, you must wait for 4-5 minutes for services to stabilize for the remaining Platform nodes.<br>3. Increase RAM, total vCPU and corresponding reservation as required to match the target brick size.<br>4. **Power On** the Platform VMs in the chronological order. For example: Restart from Node 1 to Node 3. |
| **For a collector** | 1. Log in to VMware vCenter.<br>2. Shutdown the Collector VM using the **Shut Down Guest OS** option.<br>**Note:**<br>Do not use the **Power Off** option.<br>3. Increase RAM, total vCPU and corresponding reservation of the VM as required to match the target brick size.<br>4. **Power On** the Collector VM. |

**Note:**
After you increase the brick size of the platform VM, you must reconfigure the platform VM.

### Increase the Disk Size

In VCF Operations for networks, you can add additional disk space to a VCF Operations for networks Platform node.

Ensure that the nodes are in the powered-on state, and you have the correct privileges.

If the disk usage on the Platform are high, adding more disk space helps you prevent any unwanted service interruption.

**Note:**
Do not expand the existing disks available in the VM. You must always add a new disk in the VM.

**Note:**
Do not reboot any VMs until VCF Operations for networks detects the new disk and the new disk space is added in the `/var` partition.

1. Log in to VMware vCenter using the web client with correct privileges.
2. Right-click the VM, and click **Edit Settings**.
3. Add a disk of required size.

   A cron job runs every 5 minutes and checks for any new disks added to the VM, then automatically expands the required partition.

Wait for 10-15 minutes for VCF Operations for networks to detect the disk, and then check and ensure that the additional disk size is visible in the `/var` partition.

In case troubleshooting is required, the cron job script location is: `/home/ubuntu/build-target/common-utils/cron.5m/run-expandpart.sh`. You can find the related log file at `/home/ubuntu/logs/disk_util.log`.

## Create a Support Bundle

You can create a support bundle that collects diagnostic information such as product-specific logs, configuration files of your setup. When you raise a support request, VMware Technical Support uses this information to troubleshoot your setup issues.

1. On the Settings page, click **Infrastructure and Support** > **Support**.
2. Select the platform VMs and the collector VMs for which you want to create the support bundle.

   To select all VMs, click the check box in the header of the platform VMs and the collector VMs tables.

3. Click **Create Support Bundle**.
4. Click **Yes** to confirm creation of a new support bundle.
   VCF Operations for networks takes some time to complete the creation of the bundle.

A new support bundle is created displaying date and time. To initiate the download of support bundle, click the **Download** link next to the respective VM.

**Note:**

- The support bundle creation on a medium sized system can take in excess of fifteen minutes.
- Only two support bundles can be present at one given time. So, while creating a new one, if there are already two support bundles present, the older one is deleted.

Attach the support bundle to your service request for VMware to access the details.

## Viewing System Health

In VCF Operations for networks, you can view the health status of your system. The health of your system is determined by process lag, indexer lag, and grid usage.

If all these parameters are in the green state, your system health is good. If any one of these three parameters is in the red state, your system health is bad. The overall health indicator displays the number of irregularities, with a Red light. The individual irregularities are listed with their details, when the number of problems against overall health, is clicked on. In case of normal functioning, the health indicator shines a Green light. The **Health** indicator turns red if any of the following malfunctioning events occur:

- If the collector stops collecting flow data
- If platform stops processing data due to some reason; for example, insufficient disk space
- If search indexer lags behind, resulting in outdated search result

**Note:**
VCF Operations for networks might not detect an out-of-sync system clock sometimes. If the clock is not in sync with NTP, some services may become unhealthy or stop working.

On the **Settings** page, click **Infrastructure and Support** > **Infrastructure and Updates**.

The health of your system is displayed in the **System Health** section.

**Note:**
If your system health is in the bad state for more than six hours, you must contact the VCF Operations for networks support.

### Viewing System Usage

In VCF Operations for networks, you can view and track the use of resources and see how these entities have changed over time.

The counts of entities used are tracked as metrics and these metrics are tracked once every 24 hours. These metrics have a data retention period of up to 13 months or up to the data retention interval set in the **Data Management** tab of the **Settings** page. The trending metric graphs show the counts of VMs, hosts, applications, firewall rules, daily flows, and weekly flows.

To view the metric graphs:

1. Go to **Settings** > **Infrastructure and Support** > **Infrastructure and Updates**.
2. On the Infrastructure and Updates page, click **Go to Operations for Networks System Dashboard**.
3. You can see the metric graphs under the **System Usage** section of the Overview page.

## Understanding Capacity for Collector and Platform Load

VCF Operations for networks provides the approximate capacity and load information of a collector node and a platform. This limits-based information helps you to prevent the performance and experience issues later.

### Understanding Capacity

There are two kinds of capacity:

- VM capacity: It is defined as the number of discovered VMs that a node or a setup can handle.
- Flow capacity: It is defined as the number of flows that a node or a setup can handle.

The capacity is defined as follows:

- Single platform with one or more collector nodes: The capacity of a collector node or the platform is the number of discovered VMs that it can handle without the degradation of performance.
- Cluster setup: The capacity of the platform in a cluster setup is the aggregation of all the capacities of all the platform nodes while the capacity of collector nodes is considered at the level of an individual node.

### Accessing the Capacity Information

You can view **VM Capacity** and **Flow Capacity** on the **Infrastructure and Support** > **Infrastructure and Updates** page.

For every collector node listed under Collector VMs, only the VM capacity information is provided.

> **Note:**
> When the number of discovered VMs from the data sources across the deployment exceed the capacity of either the system or the collector or both, you will not be allowed to trigger the upgrade.

To view the discovered VMs for a data source:

1. In the **Accounts and Data Sources** page, you can see the number of VMs that have been discovered for a particular data source which is already added and currently active. This column will have a value only if the data source is vCenter or AWS source.

   > **Note:**
   > The discovered VM count includes placeholder and template VMs. So it can be different from the count of VMs in the product.

## View Platform Capacity

In VCF Operations for networks, you can view the platform capacity and usage.

In the **Platform Capacity**, you see information about VMs, Active Flows, All Flows, and Devices. To view the **Platform Capacity**, do the following:

On the **Settings** page, click **Infrastructure and Support** > **Infrastructure and Updates**.

In the **Infrastructure and Updates** page, you can see the **Platform Capacity**.

### Resolving Platform Capacity Problems

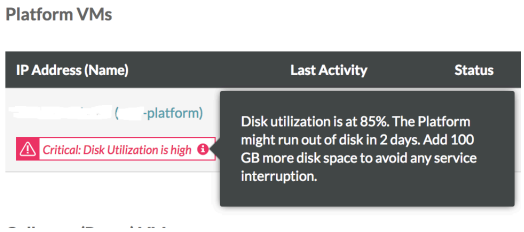
Use the information provided in the following table to resolve platform capacity-related problems.

| Error Text | Cause | Resolution |
|---|---|---|
| `Capacity configuration is mismatched.` | There is a change in the license or the brick size of the setup. | Click **RECONFIGURE**. |
| `System usage has breached the capacity.` | Your system usage has crossed the stipulated platform capacity. | You must do, one of the following:<br>• Click the **RECONFIGURE** button (if available).<br>• If you do not see the **RECONFIGURE** button, then you must add more resources to increase capacity by doing one of the following:<br>– Increase the brick size (if you are using medium or large brick).<br>– Create cluster (if you are using single node deployment).<br>– Expand the cluster (if you are using clustered deployment).<br>To know about creating and expanding clusters, see Creating and Expanding Clusters. |
| `Capacity reconfiguration failed.` | The problem can occur because of a various technical reasons. | Contact VMware Support. |

## Manage Disk Utilization

If the disk utilization is high for a platform or a collector, VCF Operations for networks triggers an alert to warn the user to manage the disk space. VCF Operations for networks also provides a recommendation of how much more disk space is to be added.

To view the alerts related to disk utilization, navigate to the platform dashboard or the collector dashboard. You can also view these alerts in the corresponding collector or the platform section in the **Infrastructure and Support** > **Infrastructure and Updates** page.



To add a hard disk to a node, perform the following steps:

> **Note:**
> Do not expand the existing hard disk.

1. Log in to VMware vCenter through the Web client with sufficient privileges.
2. Right-click the node and select **Edit settings**.
3. Add the hard disk as per recommendations provided in the alert.
   VCF Operations for networks takes a few minutes to detect the appliance and add it to the `/var` partition.

## View the Platform and Collector Details

In VCF Operations for networks, you can view the details of each platform node and collector node.

1. To view the details of a particular platform node, go to **Settings** > **Infrastructure and Support** > **Infrastructure and Updates** > **Platform VMs** and click its name from the list.

   The VCF Operations for networks platform dashboard appears.

2. To view the details of a particular collector node, go to **Settings** > **Infrastructure and Support** > **Infrastructure and Updates** > **Collector VMs** and click its name from the list.

   The VCF Operations for networks collector dashboard appears.

## Configure Data Retention Interval

In VCF Operations for networks, you can specify the duration for which you want to retain your data.

> **Note:**
> VCF Operations for networks supports configurable data management on an enterprise license only. In the advanced license edition, the data retention defaults to 1 month.

The data is divided into the following categories:

**Table 1314:**

| Category | Minimum Value | Maximum Value |
|---|---|---|
| Alerts | 1 month | 13 months |
| Entities and Configuration Data | 1 month | 3 months |
| Metrics | 1 month | 13 months |
| Flows | 1 month | 1 month |
| Miscellaneous Data | NA | 100 GB of additional disk space |

> **Note:**
> For all the categories, the minimum value is the default value.

Different policies can be configured and controlled for each category. You can configure the policy as per your requirement.

To configure data management:

1. Go to **Settings** and click **Data Management**.
2. When you log in for the first time, this page shows the default data.
3. Click **Edit** on the top-right corner of the page to change the data retention period for various categories of data.
4. Click **Submit**. The Updated information is recorded in the database.

> **Note:**
> The retention period for low-resolution metrics is longer than the high-resolution metrics.

## Configuring IP Properties and Subnets

In VCF Operations for networks, you can configure different IP properties for better security planning and identification.

### Import the DNS mapping file

You can upload your DNS mapping file on VCF Operations for networks to provide information about flows between physical devices. The supported file formats are the Bind and CSV file format. Ensure that you have placed these files in a single ZIP file.

> **Note:**
> VCF Operations for networks does not support password-protected ZIP files.

1. Go to **Settings** > **IP Properties and Subnets** > **Physical IP and DNS Mapping**.
2. Click **Upload** to upload your DNS mapping file. After you select and upload the file, click **Validate**. The number of DNS records is displayed after validation.

   The **Upload** operation removes any existing DNS mappings and replaces them with the mappings that are being imported.

   The DNS Mapping file consists of the following fields:

   - Host Name
   - IP Address (IPv4 or IPv6 address)
   - Domain Name

## Configure Mapping Between Subnet and a VLAN

You can define a mapping between subnet and a VLAN.

You can use this mapping for the following:

- Enriching the information about the IP entities that are learned from physical to physical flows by adding the source and destination subnets and the Layer2 networks associated with the flow.
- Planning the network topology based on the subnet and VLAN for physical addresses.

1. Go to **Settings** > **IP Properties and Subnets** > **Physical Subnets and VLANs**.

   This page lists all the subnets and the associated VLAN IDs.
2. Click **Add** to add the subnet and VLAN information.
3. Click **Submit**.
4. After defining the mapping information, you can only edit the VLAN ID that is associated with the subnet.You cannot change to the subnet CIDR associated with the VLAN ID. To edit a subnet associated with the VLAN ID, delete the subnet and create a new subnet VLAN mapping with the updated values.

   When the subnet-VLAN mapping information is updated, a new VLAN is created for the specified VLAN ID and the subnet information is associated with this VLAN.
5. To delete the subnet-VLAN ID mapping, click **Delete**.

   **Note:**
   All VLAN creation, updating, and deletion operations does not happen immediately after the subnet and VLAN mappings are created. It takes some time for the changes to be propagated and the corresponding VLAN to be created or modified.

## Configuring East-West and North-South IPs

In VCF Operations for networks, you can override IP addresses, IP ranges, and subnets as either private IPs (East-West IPs) or public IPs (North-South IPs).

### East-West IPs and North-South IPs

The IP addresses that are within the range of RFC1918 standard and the IP addresses of the VMs in VCF Operations for networks are considered as East-West IPs or private IPs.

The IP addresses that are outside RFC1918 are considered as North-South IPs or public IPs.

VCF Operations for networks supports both IPv4 and IPv6 addresses.

### Configuring East-West and North-South IPs

1. Go to **Settings** > **IP Properties and Subnets** > **Custom IPs** and click **Customize**.
2. In the **East-West IPs** text box, enter custom IPs that you want to override as private IPs. Custom IPs can be IP addresses, IP ranges, or subnets.
3. In the **North-South IPs** text box, enter custom IPs that you want to override as public IPs.

4. Click **Save.**

While adding the IP addresses, you can do the following actions:

- To add a single IP address, specify the IP address and press Enter.
- To add multiple IP addresses, use commas.
- To add an IP range or a subnet, specify the IP entries and press Enter.
- To add an IP range or a subnet and exclude a few IP addresses, click **Add Exceptions**, enter the exception IPs, and click **Done**.

  **Note:**
  You can add IP addresses, IP ranges, and subnets as exceptions. The IP addresses that you add as exceptions in the East-West IPs text box are considered as North-South IPs and vice versa.

## Configuring Alerts and Notifications

In VCF Operations for networks, you can configure various types of alerts and notifications. VCF Operations for networks creates an alert whenever the system meets a preset rule.

### Viewing and Editing Alert Definitions

In VCF Operations for networks, you can view various alert definitions and list of alerts related to the alert definitions.

VCF Operations for networks has the following types of alert definitions:

- **Problems**: Logical or physical problems detected by VCF Operations for networks in the environment. A problem can be something involving any entity, property, or metric. For example, a router interface failing or percent of packet drops of an interface crossing a certain threshold can be detected as a problem.
- **Changes**: Changes that are detected by VCF Operations for networks in the environment for an entity, or properties and metrics of an entity. Create, update, and delete qualifies as a change.
- **Others**: Alerts that are generated by external data sources, and not defined by VCF Operations for networks. For example, NSX-T alerts, Kubernetes alerts, and so on.

To view the alert definitions, on the **Settings** page, click **Alerts and Notification** > **Alert Definitions**.

All the alert definitions of type Problem are displayed in the **Problems** tab.

**Note:**
All the alerts of type **Problem** are also logged into syslog.

All the alert definitions of type Changes are displayed in the **Changes** tab.

All the alert definitions of type Others are displayed in the **Others** tab.

When you point the mouse on each alert, you can see the name, the description, alert tags for that alert.

You can perform the following tasks on the alerts:

- Edit an alert
- Deactivate an alert.
- Perform bulk edit, enable, and deactivate

#### Edit Alert Definitions

You can edit alert definitions and set notifications for the preferred system events.

1. Click the edit icon on the **Action** column for the problem you want to edit.
2. Change the severity.

   **Note:**
   Applicable only for Problem type - Alert Definition.

3. Add or remove event tags if required.

   **Note:**
   Applicable only for Problem type - Alert Definition.

4. Select Include/Exclude entities if you want the alert to be enabled or deactivated for selected entities.

   - To create inclusion rules:

     a. Select **Include/Exclude entities** check box.
     b. Click **INCLUDE**.
     c. Specify the entities which you want to include from the drop-down menu.
        You can specify multiple entities in the inclusion rule by adding multiple conditions by clicking **ADD CONDITION** button.

   - To create exclusion rules:

     a. Select **Include/Exclude entities** check box.
     b. Click **EXCLUDE**.
     c. Specify the entities which you want to exclude from the drop-down menu.

   **Note:**

   - You can create multiple rules in both inclusion and exclusion lists by clicking **ADD CONDITION** button.
   - You can also specify **Custom search** by writing your own query to include or exclude entities.

   **Note:**
   Applicable only for Problem type - Alert Definition.

5. To get alert notification, do the following:

| Option | Action |
|---|---|
| **If you do not have an email server configured** | Click **Configure Mail Server**. To know how to configure a mail server, see Configure Mail Server. |
| **If you have already configured an email server** | Select **Email immediately**, **Email daily digest**, or both to specify the frequency at which you want to receive the emails.<br>If you select **Email immediately**, you get email notification immediately when an alert is raised.<br>If you select **Email daily digest**, you get email notification at a pre-select time every day for all the alerts that are raised in the system. |
| **If you do not have an SNMP trap configured** | Click **Configure SNMP Trap**. To know how to configure an SNMP trap, see Configure SNMP Trap Destination. |
| **If you have already configured an SNMP trap configured** | Select one or more SNMP trap destinations from **Send SNMP Trap to** drop-down menu. You can select up to four SNMP trap destinations. |

6. Click **SUBMIT**.

**Perform a Bulk Edit on an Alert**

In VCF Operations for networks, you can edit multiple alert definitions at once.

1. In the **Alert Definitions** page, select the alerts that you want to edit.
   When you select multiple alerts, the options **ENABLE**, **DISABLE**, and **EDIT** appear above the list.

2. Click **EDIT**, and make the required changes.

| Option | Action |
|---|---|
| **Severity** | Select an option from the drop-down menu.<br>You see the following options:<br>• **No change**: Default value |

| Option | Action |
|---|---|
| | • **Override existing values**: Overwrites the existing values and sets the new value as per your selection. |
| **Tags** | Select an option from the drop-down menu.<br>You can overwrite existing tags, add new tags, or remove existing tags. |
| **Email immediately** | Select an option from the drop-down menu.<br>If you select **Enable**, you get email notification immediately when an alert is raised. |
| **Email daily digest** | Select an option from the drop-down menu.<br>If you select **Enable**, you get email notification at a pre-select time every day for all the alerts that are raised in the system. |
| **SNMP Trap** | Select an option from the drop-down menu.<br>You can enable or deactivate SNMP traps. |

3. Click **SUBMIT**.

**Deactivate an Alert**
You can deactivate alerts as needed to stop receiving notifications when certain conditions are met.

To deactivate an alert:

1. Select the alert in the **Open Problems** section of the Homepage. Or, enter **Problems** in the search bar and select an alert from the list.
2. In the more option (three vertical dots), click **Archive**.
3. Select **Disable all alerts of this type in future for** and select an entity or all entities.
4. Click **SAVE**.

> **Note:**
> The changes made in severity, tags, or inclusion/exclusion rules will reflect for the future alerts. The existing alerts continue to show the old configuration.

**Alert Limitations**
This section provides the limitations for the various alerts.

**Distributed Firewall Rule Masked by Preceding Rule alert Limitation**

This alert has the following limitations:

- This alert is supported only for NSX-T distributed and Edge firewall rules, and NSX-T on VMware Cloud on AWS firewall rules. Other firewall vendors are not supported.
- The following firewall rule properties are currently supported for masking computation:
  - Source
  - Destination
  - Applied To
  - Service protocol and Port ranges
  - Packet type
  - Layer-7 application IDs
- Rules with source or destination inversion are not supported.
- Deactivated rules are ignored.
- Rules with security groups containing excluded members directly or indirectly in Source/Destination or Applied To is not supported.
- The masking computation for Source, Destination, and Applied To properties are based on the static membership and IP range overlap of member IPSets. Dynamic membership of a security group are not considered for masking.

## Create a Search-based Alert

In VCF Operations for networks, you can define an alert through the search. Whenever you perform search, you get a option to create an alert based on your search result.

All the alerts created by users are categorized as Search-based alerts. Search-based alerts were previously know as user defined events.

> **Note:**
> If you are an existing VCF Operations for networks user, and you have configured user-defined events in your VCF Operations for networks, then when you upgrade to VCF Operations for networks version 6.1, you see all your user-defined events under the **Alert Definitions** page. Based on the event type, you can find your events under either **Problem** or **Change** tab in the **Alert Definitions** page.

1. Click

   located in upper-right corner on the search result window.
2. In the **Define Alert** page, do the following:

| Option | Action |
|---|---|
| **Name** | Enter a unique name for the alert. |
| **Search query** | Shows the search criteria for the alert. |
| **Generate alert when** | Select when you want to generate the alert. |
| **Definition type** | Select an alert type. |
| **Severity** | This field specifies the severity of the alert. You can set it to the following values:<br>• Critical<br>• Moderate<br>• Warning<br>• Info |

3. To configure how you want to send the notification, select **Alert Notification** check box and do the following:

| Option | Action |
|---|---|
| **Email frequency** | Select how frequently you want to get the notifications. |
| **Email addresses** | Enter an email address when you want to get the notifications. |
| **SNMP trap destination** | Select trap destinations from the drop-down.<br>You can select maximum four trap destinations. |

4. Click **SUBMIT**.

### Editing Search-based Alerts

In VCF Operations for networks, you can edit a search-based alert definitions.

You can edit the following options:

| Option | Action |
|---|---|
| Name | Provide a unique name. |
| Generate alert when | Select when you want to generate the alert. |
| Definition type | Select a alert type. |
| Severity | This field specifies the severity of the alert. You can set it to the following values:<br>• Critical<br>• Moderate<br>• Warning<br>• Info |

| Option | Action |
|---|---|
| Alert Notification | Configure how you want to send the notification. |

You can edit or delete the alert. While editing it, you can specify the email address and the frequency of the email notification.

## Viewing Platform Health Alerts

The Platform Health Alerts page is your one-stop page to view all the alerts that provide details on the overall health of the system. These alerts might have occurred on a data source or a node in the infrastructure. You can also view these alerts through search.

| Field | Description |
|---|---|
| Name | The name of the alert. |
| Severity | The severity of the alert. You cannot change the severity of the alert. |
| Type | The type of alert. The alert denotes a problem or a change. |
| Notifications | The types of notifications that are sent. The notifications can be sent as an email, an SNMP trap, or both. |

## Alerts List

Here is a list of all the out of the box (previously know as system defined) alerts in VCF Operations for networks. To receive notification about any of these alerts, you must enable notification for that particular alert.

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.110013 | SnapshotNotBuildingEvent | Critical | Unable to load latest network map | Unable to load latest network map |
| 1.3.6.1.4.1.6876.100.1.0.100001 | vmwNSXVLatencyNoDataEvent | Warning | NSXVLatencyNoDataEvent | Network Latency Collection Stopped |
| 1.3.6.1.4.1.6876.100.1.0.100051 | vmwVMCVMLimitExceededEvent | Critical | VMCVMLimitExceededEvent | Number of VMs in VMC SDDC exceeds limit.<br>**Note:** This alert is deprecated in VCF Operations for networks 6.1. |
| 1.3.6.1.4.1.6876.100.1.0.100052 | vmwVMCHostLimitExceededEvent | Critical | VMCHostLimitExceededEvent | Number of Hosts in VMC SDDC exceeds limit.<br>**Note:** This alert is deprecated in VCF Operations for networks 6.1. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.1510 | vmwKubernetesBaseEvent | Moderate | System Alerts from Kubernetes | Alert reported by kubernetes cluster |
| 1.3.6.1.4.1.6876.100.1.0.20001 | vmwEntityDiscoveryChangeEvent | Info | Discovery | This alert is raised when any new entity is discovered |
| 1.3.6.1.4.1.6876.100.1.0.20002 | vmwEntityPropertiesChangeEvent | Info | Configuration Change | This alert is raised when any property of the entity is changed |
| 1.3.6.1.4.1.6876.100.1.0.20003 | vmwFirewallNotInstalledOnHostEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20004 | vmwHostWithStaleFirewallRulesEvent | Warning | Firewall rule table mismatched between host and NSX Manager | The distributed firewall rule table differs between the host and NSX Manager. |
| 1.3.6.1.4.1.6876.100.1.0.20005 | vmwIpAddressChangeEvent | Info | IP address change | This alert is raised when IP Address of VM is changed |
| 1.3.6.1.4.1.6876.100.1.0.20006 | vmwL2GatewayAnomalyEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20007 | vmwL2NetworkAddressAnomalyEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20008 | vmwL2NetworkDiameterExceededEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20009 | vmwL2NetworkUplinkMissingEvent | Info | Uplink not found for distributed virtual port group | VxLan does not have an uplink on specified Host |
| 1.3.6.1.4.1.6876.100.1.0.20010 | vmwL2NetworkWithNoVMsEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20011 | vmwLayer2NetworkDiameterChangedEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20012 | vmwMTUMismatchEvent | Warning | MTU mismatched between VTEP and physical switch port | An MTU mismatch was found in the path between a VTEP and its physical switch port |
| 1.3.6.1.4.1.6876.100.1.0.20013 | vmwNetworkIsolationEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20014 | vmwNoPathEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20015 | vmwSpoofguardDisabledEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20018 | vmwVMotionEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20019 | vmwVMWithDisconnectedVnicsEvent | N/A | N/A | N/A |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.20020 | vmwVMWithMulipleVnicsOnDifferentVxlansEvent | N/A | N/A | vm %s is connected to more than one vxlans [%s] |
| 1.3.6.1.4.1.6876.100.1.0.20021 | vmwVMWithMulipleVnicsOnSameL2Event | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20022 | vmwVMWithNoIpAddressEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20023 | vmwVTEPMissingEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20024 | vmwL2Event | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20025 | vmwMembershipChangeEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20026 | vmwSecurityGroupMembershipChangeEvent | Info | Security Group VM membership change | This alert is raised when membership of Security Group is changed |
| 1.3.6.1.4.1.6876.100.1.0.20027 | vmwFirewallRuleMembershipChangeEvent | Info | Firewall Rule VM membership change | This alert is raised when membership of Firewall Rule is changed |
| 1.3.6.1.4.1.6876.100.1.0.20028 | vmwVlanMembershipChangeEvent | Info | VLAN VM membership change | This alert is raised when membership of Vlan is changed |
| 1.3.6.1.4.1.6876.100.1.0.20029 | vmwVxlanMembershipChangeEvent | Info | VXLAN VM membership change | This alert is raised when membership of Vxlan is changed |
| 1.3.6.1.4.1.6876.100.1.0.20030 | vmwDeleteChangeEvent | Info | Delete change | This alert is raised when any entity is deleted |
| 1.3.6.1.4.1.6876.100.1.0.20031 | vmwVtepFailedPingEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20034 | vmwEmptySearchStreamChangeEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20035 | vmwSearchStreamMembershipChangeEvent | N/A | User Defined Change Alert | User defined Change Alert |
| 1.3.6.1.4.1.6876.100.1.0.20036 | vmwEmptySearchStreamProblemEvent | N/A | User-defined zero result issue | User defined Problem when search result is empty |
| 1.3.6.1.4.1.6876.100.1.0.20037 | vmwSearchStreamMembershipProblemEvent | N/A | User-defined change issue | User defined Problem when search result changes |
| 1.3.6.1.4.1.6876.100.1.0.20038 | vmwOspfConfigurationMismatchEvent | Moderate | OSPF area ID mismatched between DLR and Edge router | The OSPF area ID differs on connected router interfaces. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.20039 | vmwServiceVMNotHealthyEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20040 | vmwServiceVMNotPoweredOnEvent | Critical | NSX infrastructure VM not powered on | The NSX infrastructure VM found to be in powered off state. Services provided by it may get impacted. The NSX infrastructure includes Controller cluster |
| 1.3.6.1.4.1.6876.100.1.0.20041 | vmwServiceVMHighCPUUsageEvent | Warning | High CPU reported for NSX infrastructure VM | An NSX infrastructure VM is experiencing high CPU. This condition may lead to a service disruption. |
| 1.3.6.1.4.1.6876.100.1.0.20042 | vmwServiceVMHighMemoryUsageEvent | Warning | High memory usage reported for NSX infrastructure VM | An infrastructure VM is experiencing a high memory condition. This condition may lead to an NSX service disruption. |
| 1.3.6.1.4.1.6876.100.1.0.20043 | vmwServiceVMHighDiskUsageEvent | Warning | High disk usage reported for NSX infrastructure VM | Most of the allocated disk space for an infrastructure VM has been consumed. The infrastructure VM may become inaccessible or lead to a service disruption. |
| 1.3.6.1.4.1.6876.100.1.0.20050 | vmwIPSetPropertiesChangeEvent | Info | IP Set properties change | This alert is raised when any property of IPSet is changed |
| 1.3.6.1.4.1.6876.100.1.0.20051 | vmwFirewallRulePropertiesChangeEvent | Info | Firewall Rule properties change | This alert is raised when any property of Firewall Rule is changed |
| 1.3.6.1.4.1.6876.100.1.0.20052 | vmwSecurityGroupPropertiesChangeEvent | Info | Security Group properties change | This alert is raised when any property of Security Group is changed |
| 1.3.6.1.4.1.6876.100.1.0.20053 | vmwIPSetMembershipChangeEvent | Info | IP Set membership change | This alert is raised when membership of IPSet is changed |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.20054 | vmwFirewallRuleMaskEvent | Warning | Firewall rule masked by preceding rule | A distributed firewall rule is masked by one or more preceding rules. This condition may indicate a configuration error |
| 1.3.6.1.4.1.6876.100.1.0.20056 | vmwSecurityMembershipChangeEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20057 | vmwSecurityTagPropertiesChangeEvent | Info | Security Tag properties change | This alert is raised when any property of Security Tag is changed |
| 1.3.6.1.4.1.6876.100.1.0.20058 | vmwSecurityTagMembershipChangeEvent | Info | Security Tag VM membership change | This alert is raised when membership of Security Tag is changed |
| 1.3.6.1.4.1.6876.100.1.0.20059 | vmwHostDatastoreChangeEvent | Info | Datastores of Host changed | This alert is raised when Host Datastore is changed |
| 1.3.6.1.4.1.6876.100.1.0.20060 | vmwVMDatastoreChangeEvent | Info | Datastores of VM changed | This alert is raised when VM Datastore is changed |
| 1.3.6.1.4.1.6876.100.1.0.20061 | vmwVMSnapshotChangeEvent | Info | Snapshots of VM changed | This alert is raised when Snapshot of VM is changed |
| 1.3.6.1.4.1.6876.100.1.0.20062 | vmwVMVirtualDiskChangeEvent | Info | Virtual Disks of VM changed | This alert is raised when Virtual Disk of VM is changed |
| 1.3.6.1.4.1.6876.100.1.0.20063 | vmwIPSetDefinitionMismatchEvent | Info | IPSet definition mismatched between NSX Managers | An IPSet with the same name and different scopes is defined in two NSX Managers. This condition may indicate a configuration error. |
| 1.3.6.1.4.1.6876.100.1.0.20064 | vmwSegmentMismatchEvent | Info | Segment ID ranges overlap between two NSX Managers | The VXLAN segment ID ranges defined in different NSX Managers have overlapping ranges |
| 1.3.6.1.4.1.6876.100.1.0.20065 | vmwVtepEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20066 | vmwVtepConfigurationFaultEvent | N/A | N/A | N/A |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.20067 | vmwDLRNetworksNotReachableEvent | Critical | DLR networks unreachable from NSX Edge or external router | One or more DLR networks cannot be reached from the uplink interface on the NSX Edge router. This condition suggests either an OSPF configuration error on the Edge-router/ DLR or route not configured on uplink router. |
| 1.3.6.1.4.1.6876.100.1.0.20068 | vmwVtepSubnetMismatchEvent | Moderate | VTEP IP subnet mismatched between host(s) and NSX prepared cluster | One or more host VTEPs' IP addresses are not on the same subnet as other VTEPs in the same cluster. This condition may result in network connectivity issues |
| 1.3.6.1.4.1.6876.100.1.0.20069 | vmwVtepCountMismatchEvent | Critical | Host's VTEP count mismatched with cluster | The host's VTEP count doesn't match the VTEP count of other hosts in the same cluster. VMs on this host connected to a logical switch may not be able to communicate. |
| 1.3.6.1.4.1.6876.100.1.0.20070 | vmwEdgeNetworksNotReachableEvent | Moderate | NSX Edge network unreachable from uplink router | One or more networks connected to an NSX Edge router are not reachable from an uplink router. |
| 1.3.6.1.4.1.6876.100.1.0.20089 | vmwNiInfraChangeEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.20090 | vmwDataSourceEnabledChangeEvent | Info | Data source has been enabled | This alert is raised when data source is enabled |
| 1.3.6.1.4.1.6876.100.1.0.20091 | vmwDataSourceDisabledChangeEvent | Info | Data source has been deactivated | This alert is raised when data source is deactivated |
| 1.3.6.1.4.1.6876.100.1.0.20092 | vmwDataSourceCreatedEvent | Info | Data source has been added | This alert is raised when a data source is added |
| 1.3.6.1.4.1.6876.100.1.0.20093 | vmwPlatformCpuCoreChangeEvent | Info | Platform CPU Cores Change | This alert is raised when CPU cores on platform is changed |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.20094 | vmwPlatformDiskChangeEvent | Info | Platform Disk Change | This alert is raised when Disk on platform is changed |
| 1.3.6.1.4.1.6876.100.1.0.20095 | vmwPlatformMemoryChangeEvent | Info | Platform Memory Change | This alert is raised when memory on platform is changed |
| 1.3.6.1.4.1.6876.100.1.0.20096 | vmwPlatformRebootedEvent | Info | Platform Rebooted | This alert is raised when platform is rebooted |
| 1.3.6.1.4.1.6876.100.1.0.20097 | vmwProxyCpuCoreChangeEvent | Info | Proxy CPU Cores Change | This alert is raised when CPU cores on collector is changed |
| 1.3.6.1.4.1.6876.100.1.0.20098 | vmwProxyDiskChangeEvent | Info | Proxy Disk Change | This alert is raised when Disk on collector is changed |
| 1.3.6.1.4.1.6876.100.1.0.20099 | vmwProxyMemoryChangeEvent | Info | Proxy Memory Change | This alert is raised when memory on collector is changed |
| 1.3.6.1.4.1.6876.100.1.0.20100 | vmwProxyRebootedEvent | Info | Proxy Rebooted | This alert is raised when collector is rebooted |
| 1.3.6.1.4.1.6876.100.1.0.20101 | vmwNIClusterChangeEvent | Info | Cluster has been expanded | This alert is raised when a platform is added to system |
| 1.3.6.1.4.1.6876.100.1.0.20102 | vmwNISystemProxyChangeEvent | Info | Proxy has been added/removed | This alert is raised when proxy is added or removed |
| 1.3.6.1.4.1.6876.100.1.0.20103 | vmwNIClusterCreateEvent | Info | Cluster has been created | This alert is raised when a cluster is created |
| 1.3.6.1.4.1.6876.100.1.0.30001 | vmwThresholdExceededEventCpuReady | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.30002 | vmwThresholdExceededEventCpuCoStop | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.30003 | vmwThresholdExceededEventDiskCommandAbortRule | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.30004 | vmwThresholdExceededEventIODeviceLatencyRule | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.30005 | vmwThresholdExceededEventIOKernelLatencyRule | N/A | N/A | N/A |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.36027 | vmwHostVtepNotFoundEvent | Critical | No VTEP found on prepared host | A host in a cluster prepared for NSX is missing at least one VTEP. VMs on this host connected to any logical switch may not be able to communicate. |
| 1.3.6.1.4.1.6876.100.1.0.36028 | vmwHostVtepDisconnectedEvent | Warning | Host's VTEP is administratively deactivated | The host's VTEP has been deactivated and is in a not connected state. |
| 1.3.6.1.4.1.6876.100.1.0.36029 | vmwHostVtepEvent | Critical | Host Vtep Disconnected | Host Vtep Disconnected |
| 1.3.6.1.4.1.6876.100.1.0.36030 | vmwClusterHostsVtepMTUMismatchEvent | Warning | VTEP MTU mismatched between host and NSX prepared cluster | The VTEP MTU does not match between a host and the NSX prepared cluster. |
| 1.3.6.1.4.1.6876.100.1.0.36031 | vmwFeatureUnhealthyEvent | Warning | Network fabric feature status in errored state | The installed NSX feature is reported for some problem by NSX Manager. |
| 1.3.6.1.4.1.6876.100.1.0.36032 | vmwEdgeHANotConfiguredEvent | Info | NSX Edge high availability not enabled | High Availability is not enabled on the NSX Edge |
| 1.3.6.1.4.1.6876.100.1.0.36033 | vmwEdgeInterfacesDownEvent | Warning | One or more NSX Edge logical router interfaces are down | One or more NSX Edge interfaces are down. |
| 1.3.6.1.4.1.6876.100.1.0.36041 | vmwModuleUnhealthyEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.36042 | vmwModuleNotLoadedEvent | Critical | NSX VIB or host module not detected on host | At least one of NSX VIB or host module was not detected on the host |
| 1.3.6.1.4.1.6876.100.1.0.36043 | vmwModuleNetworkConnectionFailureEvent | Critical | Message bus and/or control plane connection not established between NSX Manager and host | The message bus and/or control plane agent daemon on this Host is experiencing connection failures with NSX Controller or NSX Manager |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.36044 | vmwHostNetworkControlPlaneMismatchEvent | Moderate | Logical switch table mismatched between host and NSX controller | Logical switch information between the primary NSX controller and all hosts where the logical switch is used does not match. This alert may indicate an error condition is occurring after a sharding change. |
| 1.3.6.1.4.1.6876.100.1.0.36045 | vmwHostNetworkControlPlaneConnectionFailureEvent | Critical | Host control plane to controller connection not established for one or more logical switches | The connection between the control plane agent on an NSX host and its primary NSX Controller for one or more logical switches is not established. This condition can result in stale information on the host and NSX Controllers. |
| 1.3.6.1.4.1.6876.100.1.0.36046 | vmwHostNetworkControlPlaneNotSyncedEvent | Moderate | Logical networking out of sync between host and NSX Controller | The logical switching and routing information on a host is not in sync with the NSX Controller information. To confirm this condition is occurring |
| 1.3.6.1.4.1.6876.100.1.0.36047 | vmwNSXControllerClusterMajorityEvent | Moderate | No NSX controller majority | Some of the NSX Controllers in the cluster are not communicating with the NSX Manager |
| 1.3.6.1.4.1.6876.100.1.0.36048 | vmwNSXControllersVMOnSameHostEvent | Info | All controller VMs deployed to same host | All NSX Controllers in the cluster are deployed to the same host |
| 1.3.6.1.4.1.6876.100.1.0.36049 | vmwVxLanRangeExhaustEvent | Warning | VXLAN segment ID range reaching exhaustion | More than 90% of VXLAN segment IDs have been used |
| 1.3.6.1.4.1.6876.100.1.0.36050 | vmwNSXFirewallDefaultAllowAllRulesEvent | Info | All traffic allowed by default firewall rule | The distributed firewall is configured to allow all traffic by default |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.36051 | vmwLogicalRouterNoUplinkEvent | Info | NSX DLR deployed without an uplink interface | The NSX DLR does not have an uplink interface configured |
| 1.3.6.1.4.1.6876.100.1.0.36052 | vmwEdgeNotHAEvent | Info | NSX Edge is configured but not highly available | When two Edge VMs have been configured for Edge high availability |
| 1.3.6.1.4.1.6876.100.1.0.36053 | vmwEdgeNotDeployedEvent | Info | NSX Edge deployment failed | An NSX Edge has failed to deploy. This condition may indicate that an NSX Edge has been configured without actually being deployed. |
| 1.3.6.1.4.1.6876.100.1.0.36054 | vmwEcmpIsEnabledAndStatefulServicesAreUpEvent | Info | NSX Edge configured with both ECMP and stateful edge services | A firewall |
| 1.3.6.1.4.1.6876.100.1.0.36055 | vmwLogicalRouterDeployedOnEcmpEdgeHostEvent | Info | NSX DLR deployed to same host as one or more NSX ECMP Edges | The NSX distributed logical router control VM is deployed to the same host as one or more NSX Edges that are configured for ECMP. |
| 1.3.6.1.4.1.6876.100.1.0.36056 | vmwEdgeMissingInterfaceOSPFAreaMappingEvent | Info | Missing NSX Edge interface to OSPF area mapping | OSPF is enabled on the NSX Edge |
| 1.3.6.1.4.1.6876.100.1.0.36057 | vmwOspfInsecureAuthRouterEvent | Info | Insecure authentication used in one or more OSPF areas | One or more OSPF areas on the NSX Edge Services Gateway or DLR are not configured to use MD5 authentication |
| 1.3.6.1.4.1.6876.100.1.0.36058 | vmwNSXControllersDeployedCountEvent | Info | Incorrect number of deployed NSX Controllers | There are fewer than three controllers deployed |
| 1.3.6.1.4.1.6876.100.1.0.36059 | vmwNSXControllerNotActiveCountEvent | Moderate | Less than three active NSX Controllers | There are fewer than three active controllers |

| 1.3.6.1.4.1.6876.100.1.0.37003 | vmwAnalyticsThresholdEvent | Critical | Threshold violation alert | Alert generated as a result of the specified metric crosses the upper or lower bound specified in the configuration |
| 1.3.6.1.4.1.6876.100.1.0.38001 | vmwVMCEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.40000 | SwitchPortRxNetworkUsageThresholdExceededEvent | Warning | PNIC Rx Network Utilization is high | PNIC utilization exceeds the threshold value of 75%. |
| 1.3.6.1.4.1.6876.100.1.0.40001 | vmwCriticalHostNotAccessibleEvent | Critical | Host with Infrastructure VMs cannot be accessed | Host with Infrastructure VMs cannot be accessed |
| 1.3.6.1.4.1.6876.100.1.0.40002 | SwitchPortTxNetworkUsageThresholdExceededEvent | Warning | PNIC Tx Network Utilization is high | PNIC utilization exceeds the threshold value of 75%. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.40003 | SwitchPortRxNetworkUsageThresholdExceededCriticalEvent | Critical | PNIC Rx Network Utilization is high | PNIC utilization exceeds the threshold value of 90%. |
| 1.3.6.1.4.1.6876.100.1.0.40004 | SwitchPortTxNetworkUsageThresholdExceededCriticalEvent | Critical | PNIC Tx Network Utilization is high | PNIC utilization exceeds the threshold value of 90%. |
| 1.3.6.1.4.1.6876.100.1.0.40005 | ManagementHostHighCPUUsageEvent | Warning | Management Host CPU Usage | Host CPU utilization exceeds the threshold value of 75%. |
| 1.3.6.1.4.1.6876.100.1.0.40006 | ManagementHostHighCPUUsageCriticalEvent | Critical | Management Host CPU Usage Critical alert | Host CPU utilization exceeds the threshold value of 90%. |
| 1.3.6.1.4.1.6876.100.1.0.40007 | HostUnHealthyEvent | Critical | Host is not healthy | Host is not healthy |
| 1.3.6.1.4.1.6876.100.1.0.40008 | FileSystem Disk Available of NSX Controller is Low | Critical | FileSystem Disk Available of NSX Controller is Low | NSX Controller file system disk available percentage less than threshold value. |
| 1.3.6.1.4.1.6876.100.1.0.40011 | EdgeVmVnicRxPacketDropEvent | Critical | Receive packets are getting dropped on the VNIC of Edge VM. | Packets are getting dropped on the VNIC of Edge VM. This may impact the network traffic related to management nodes. |
| 1.3.6.1.4.1.6876.100.1.0.40012 | EdgeVmVnicTxPacketDropEvent | Critical | Transmit packets are getting dropped on the VNIC of Edge VM. | Packets are getting dropped on the VNIC of Edge VM. This may impact the network traffic related to management nodes. |
| 1.3.6.1.4.1.6876.100.1.0.40013 | ManagementHostPnicRxPacketDropEvent | Critical | Receive packets are getting dropped on the PNIC of the management host. | Packets are getting dropped on the pNIC of the management host. This may impact the network traffic related to management nodes. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.40014 | ManagementHostPnicTxPacketDropEvent | Critical | Transmit packets are getting dropped on the PNIC of the management host. | Packets are getting dropped on the pNIC of the management host. This may impact the network traffic related to management nodes. |
| 1.3.6.1.4.1.6876.100.1.0.40015 | ManagementHostConnectionStateDisconnectedEvent | Critical | Management Host is disconnected | vCenter has suspended management of the host. This might be due to - explicitly disconnecting the host, or trying to connect to a host which is in not responding state, or host license has expired. This results in vCenter deactivating HA on the host and hence, VMs on the host are therefore not failed over in the alert of a host isolation. |
| 1.3.6.1.4.1.6876.100.1.0.568 | vmwArkinApplicationMemberLimitEvent | Info | Application Membership limit exceeded | Number of members in application exceeds supported limit |
| 1.3.6.1.4.1.6876.100.1.0.70000 | vmwGenericNSXSystemEvent | Moderate | System Alerts from NSX (warning) | NSX System alerts with high or major severity |
| 1.3.6.1.4.1.6876.100.1.0.70001 | vmwFilterConfigApplyOnHostFailedEvent | Warning | Distributed firewall update for host vNIC failed to be applied | A distributed firewall configuration update failed to be applied to a vNIC on an NSX prepared host. |
| 1.3.6.1.4.1.6876.100.1.0.70002 | vmwRulesetLoadOnHostFailedEvent | Warning | Distributed firewall update failed to be applied to host | A distributed firewall ruleset was not applied to a host. |
| 1.3.6.1.4.1.6876.100.1.0.70003 | vmwConfigUpdateOnHostFailedEvent | Warning | Distributed firewall configuration update failed | Firewall configuration update to an NSX host has timed out. The host is not synced with the latest firewall configuration version. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.70004 | vmwSpoofguardConfigUpdateOnHostFailedEvent | Info | SpoofGuard configuration update failed | An update to the SpoofGuard configuration failed for the host. |
| 1.3.6.1.4.1.6876.100.1.0.70005 | vmwApplyRuleToVnicFailedEvent | Warning | Distributed firewall rule not applied to host vNIC | A distributed firewall rule was not applied to a host's vNIC. |
| 1.3.6.1.4.1.6876.100.1.0.70006 | vmwContainerConfigUpdateOnVnicFailedEvent | Warning | Distributed firewall container update failed on host | Network and security container information used with the vDefend distributed firewall or with Service Composer failed to be updated on an NSX host. |
| 1.3.6.1.4.1.6876.100.1.0.70007 | vmwSpoofguardApplyToVnicFailedEvent | Info | SpoofGuard initial configuration failed | The SpoofGuard configuration was not applied to the specified vNIC on the host. |
| 1.3.6.1.4.1.6876.100.1.0.70008 | vmwHostMessagingConfigurationFailedEvent | Warning | Host messaging configuration update failed | A configuration update pushed to hosts over the NSX messaging channel did not complete. |
| 1.3.6.1.4.1.6876.100.1.0.70009 | vmwHostMessagingConnectionReconfigurationFailedEvent | Warning | Host messaging connection re-config failed | Updated information on the host messaging channel failed to be sent to the NSX host. |
| 1.3.6.1.4.1.6876.100.1.0.70010 | vmwHostMessagingConfigurationFailedNotificationSkippedEvent | Warning | Host messaging channel between host and NSX Manager failed to re-establish | NSX Manager attempted to re-establish the message bus channel when the prepared host connected back to vCenter. This connection again failed |
| 1.3.6.1.4.1.6876.100.1.0.70011 | vmwHostMessagingInfrastructureDownEvent | Warning | Host messaging infrastructure down on host | Two or more messaging-channel heartbeat messages between NSX Manager and an NSX host were missed. |
| 1.3.6.1.4.1.6876.100.1.0.70012 | vmwEdgeVMNotRespondingEvent | Moderate | NSX Edge to NSX Manager heartbeat failed | An NSX Edge VM is not responding to health check by NSX Manager |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.70013 | vmwEdgeUnhealthyEvent | Critical | NSX Edge VM not in active/self state | NSX Edge VM is reporting a problematic state and might not be functioning correctly. |
| 1.3.6.1.4.1.6876.100.1.0.70014 | vmwEdgeVMCommunicationFailureEvent | Critical | NSX Manager to Edge VM communication failure | Communication failure detected between NSX Manager and Edge VM. |
| 1.3.6.1.4.1.6876.100.1.0.70015 | vmwNSXEdgeEvent | N/A | N/A | N/A |
| 1.3.6.1.4.1.6876.100.1.0.71000 | vmwOtherCriticalNSXEvent | Critical | System Alerts from NSX (Critical) | NSX System alerts with critical severity. |
| 1.3.6.1.4.1.6876.100.1.0.80001 | vmwPanNsxNotInRegisteredStateEvent | Critical | Palo Alto Panorama not registered with NSX Manager | Panorama is not in a registered state with NSX Manager. |
| 1.3.6.1.4.1.6876.100.1.0.80002 | vmwPanNsxDynamicUpdateDelayedEvent | Warning | Panorama dynamic membership definition update delayed | Panorama dynamic membership definition update from NSX Manager is delayed. This condition may indicate a network connectivity issue or an issue with NSX Manager's NetX service. |
| 1.3.6.1.4.1.6876.100.1.0.80003 | vmwPanDeviceInDisconnectedStateEvent | Warning | Palo Alto service VM not connected to Panorama | A service VM or device for Palo Alto Networks is in a not connected state with Panorama |
| 1.3.6.1.4.1.6876.100.1.0.80004 | vmwPanNsxServiceApplianceViewMismatchEvent | Critical | Service VM's status mismatched between Panorama and NSX Manager | Mismatch in service appliance information between NSX Manager and Panorama. |
| 1.3.6.1.4.1.6876.100.1.0.80005 | vmwPanNsxFabricAgentNotFoundOnHostEvent | Critical | NSX Fabric Agent not found on Host | Security Fabric Agent not reported by NSX for a Host where as the Cluster is prepped |
| 1.3.6.1.4.1.6876.100.1.0.80006 | vmwPanNsxServiceVMNotFoundOnHostEvent | Critical | Palo Alto service VM not found on host | A Palo Alto Networks' security appliance VM was not found on a host in an NSX prepared cluster. |
| 1.3.6.1.4.1.6876.100.1.0.80100 | vmwCheckpointEvent | N/A | N/A | N/A |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80102 | vmwCheckpointNsxFabricAgentNotFoundOnHostEvent | Critical | CheckpointNsxFabricAgentNotFoundOnHostEvent | Security Fabric Agent not reported by NSX for a Host where as the Cluster is prepped |
| 1.3.6.1.4.1.6876.100.1.0.80103 | vmwCheckpointNsxServiceVMNotFoundOnHostEvent | Critical | CheckpointNsxServiceVMNotFoundOnHostEvent | A Check Point' security appliance VM was not found on a host in an NSX prepared cluster. |
| 1.3.6.1.4.1.6876.100.1.0.80104 | vmwCheckpointGatewaySicStatusNotCommunicatingEvent | Critical | CheckpointGatewaySicStatusNotCommunicatingEvent | A service VM or gateway for Check Point does not have 'communicating' SIC status |
| 1.3.6.1.4.1.6876.100.1.0.80105 | vmwCheckpointNsxServiceApplianceViewMismatchEvent | Critical | Service VM's status mismatched between Check Point and NSX Manager | Mismatch in service appliance information between NSX Manager and Check Point. |
| 1.3.6.1.4.1.6876.100.1.0.80200 | NSXTEvent | N/A | NSX-T System alert | Alarm/Event generated by NSX-T platform |
| 1.3.6.1.4.1.6876.100.1.0.80201 | NSXTVcNotAddedEvent | Warning | One or more vCenter instances not added as data source in VCF Operations for networks | NSX-T has one or more Compute Managers which are not added as data sources in VCF Operations for networks with same IP or FQDN. |
| 1.3.6.1.4.1.6876.100.1.0.80202 | NSXTStandaloneHostsEvent | Warning | One or more Fabric Nodes are added as standalone hosts in NSX-T | One or more Fabric Nodes are added as standalone hosts in NSX-T. Virtual Machines on those hosts will not be visible in VCF Operations for networks. |
| 1.3.6.1.4.1.6876.100.1.0.80203 | vmwNSXTSystemEvent | N/A | System Alerts from NSX-T | Alarm generated by NSX-T platform |
| 1.3.6.1.4.1.6876.100.1.0.80205 | NSXTNoUplinkConnectivityEvent | Warning | NSX-T Tier-1 logical router disconnected | NSX-T Tier-1 logical router is disconnected from Tier-0 router. Networks under this router are not reachable from outside and vice versa. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80206 | NSXTRoutingAdvertisementEvent | Warning | Routing advertisement deactivated | Routing advertisement is deactivated for NSX-T Tier-1 logical router. Networks under this router are not reachable from outside. |
| 1.3.6.1.4.1.6876.100.1.0.80207 | NSXTManagerConnectivityDownEvent | Critical | NSX-T Edge Node has no manager connectivity | NSX-T Edge Node has lost manager connectivity. |
| 1.3.6.1.4.1.6876.100.1.0.80208 | NSXTControllerConnectivityDegradedEvent | Warning | Controller connectivity degraded for NSX-T Edge Node | NSX-T Edge Node is not able to communicate with one or more controllers. |
| 1.3.6.1.4.1.6876.100.1.0.80209 | NSXTControllerConnectivityDownEvent | Critical | NSX-T Edge Node has no controller connectivity | NSX-T Edge Node is not able to communicate with any of the controllers. |
| 1.3.6.1.4.1.6876.100.1.0.80210 | NSXTMtuMismatchEvent | Warning | MTU mismatch between NSX-T Tier-0 and uplink switch/router | The MTU configured on interfaces of Tier-0 logical router does not match with the interfaces of uplink switch/router from same L2 network. This can impact the network performance. |
| 1.3.6.1.4.1.6876.100.1.0.80211 | NSXTExcludedVmFlowEvent | Info | One or More VMs excluded from NSX-T DFW Firewall. | One or more VMs are not protected by NSX-T DFW firewall. VCF Operations for networks will not receive IPFIX flows for these VMs. |
| 1.3.6.1.4.1.6876.100.1.0.80212 | NSXTDoubleVlanTaggingEvent | Warning | Uplink Vlan misconfiguration | Communication is disrupted because VLAN on uplink port of Tier 0 router is different than VLAN on the external gateway. |
| 1.3.6.1.4.1.6876.100.1.0.80213 | NSXTNoTzAttachedOnTnEvent | Warning | No transport zone is attached to the transport node. | No transport zone attached to the transport node. VMs might lose connectivity because of this. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80214 | NSXTVtepDeleteEvent | Warning | No VTEP available on the transport node. | All vteps are deleted from the transport node. VMs might lose connectivity because of this. |
| 1.3.6.1.4.1.6876.100.1.0.80215 | vmwDuplicateL3SwitchEvent | Critical | Same Switch or Router added | Same Switch or Router is added with different IPs. VM to VM path may not be generated. |
| 1.3.6.1.4.1.6876.100.1.0.80216 | vmwLBPoolMemberDownEvent | Critical | Pool Member Down | This alert is raised when pool member of load balancer is down. To know the pool members which are down, search 'Pool Member where state = DISABLED' |
| 1.3.6.1.4.1.6876.100.1.0.80217 | vmwLBPoolDownEvent | Critical | Pool Down | This alert is raised when pool of load balancer is down |
| 1.3.6.1.4.1.6876.100.1.0.80218 | vmwLBPoolEmptyEvent | Critical | Pool Empty | This alert is raised when pool of load balancer is empty. To know pools which are empty, search 'Pool where PoolMembers Count = 0' |
| 1.3.6.1.4.1.6876.100.1.0.80219 | vmwLBPoolMemberVMDownEvent | Critical | VM of Pool Member Down | This alert is raised when VM associated with pool member of load balancer is down |
| 1.3.6.1.4.1.6876.100.1.0.80220 | vmwLBVirtualServerDisableEvent | Critical | Virtual Server of Load Balancer Deactivated | This alert is raised when virtual server of load balancer is deactivated |
| 1.3.6.1.4.1.6876.100.1.0.80221 | vmwLBServiceNodeIPNotFoundEvent | Critical | IP of Service Node not found | This alert is raised when no NIC associated with IP of service node of load balancer is found |
| 1.3.6.1.4.1.6876.100.1.0.80222 | vmwLBServiceNodeMultipleNicFoundEvent | Critical | Multiple NIC of Service Node found | This alert is raised when multiple NICs associated with IP of service node of load balancer are found |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80223 | NSXTSwitchIpfixEnabledEvent | Warning | NSX-T Switch IPFIX is enabled and has a collector profile pointing to one of the collectors. | VCF Operations for networks does not support the IPFIX flow data from NSX-T Switches. It is configured to send IPFIX data to one of the VCF Operations for networks Collector VM. It may have corrupted existing flow data in the system. |
| 1.3.6.1.4.1.6876.100.1.0.80224 | NSXTStandaloneHostsWithoutVcEvent | Critical | vCenter managing one or more fabric nodes in NSX-T is not added as a data source in VCF Operations for networks | vCenter managing one or more fabric nodes in NSX-T is not added as a data source in VCF Operations for networks. Virtual Machines on those hosts will not be visible in VCF Operations for networks. |
| 1.3.6.1.4.1.6876.100.1.0.80225 | NSXTControllerNodeToControlClusterConnectivityEvent | Critical | NSX-T controller node has no control cluster connectivity | NSX-T controller node has lost control cluster connectivity. |
| 1.3.6.1.4.1.6876.100.1.0.80226 | NSXTControllerNodeToMgmtPlaneConnectivityEvent | Critical | NSX-T controller node has no management plane connectivity | NSX-T controller node has lost management plane connectivity. |
| 1.3.6.1.4.1.6876.100.1.0.80227 | NSXTMPNodeToMgmtClusterConnectivityEvent | Critical | NSX-T management node has no management cluster connectivity | NSX-T management node has lost management cluster connectivity. |
| 1.3.6.1.4.1.6876.100.1.0.80228 | NSXTHostNodePnicStatusDownEvent | Warning | NSX-T Host Transport Node Pnic Status is 'Down'. | NSX-T Host Transport Node Pnic Status is 'Down'. |
| 1.3.6.1.4.1.6876.100.1.0.80229 | NSXTHostNodePnicStatusDegradedEvent | Warning | NSX-T Host Transport Node Pnic Status is 'Degraded' | NSX-T Host Transport Node Pnic Status is 'Degraded'. |
| 1.3.6.1.4.1.6876.100.1.0.80230 | NSXTHostNodePnicStatusUnknownEvent | Warning | NSX-T Host Transport Node Pnic Status is 'Unknown'. | NSX-T Host Transport Node Pnic Status is 'Unknown'. |
| 1.3.6.1.4.1.6876.100.1.0.80231 | NSXTHostNodeTunnelStatusDownEvent | Warning | NSX-T Host Transport Node Tunnel Status is 'Down'. | NSX-T Host Transport Node Tunnel Status is 'Down'. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80232 | NSXTHostNodeTunnelStatusDegradedEvent | Warning | NSX-T Host Transport Node Tunnel Status is 'Degraded'. | NSX-T Host Transport Node Tunnel Status is 'Degraded'. |
| 1.3.6.1.4.1.6876.100.1.0.80233 | NSXTHostNodeTunnelStatusUnknownEvent | Warning | NSX-T Host Transport Node Tunnel Status is 'Unknown'. | NSX-T Host Transport Node Tunnel Status is 'Unknown'. |
| 1.3.6.1.4.1.6876.100.1.0.80234 | NSXTHostNodeStatusDownEvent | Warning | NSX-T Host Transport Node Status is 'Down'. | NSX-T Host Transport Node Status is 'Down'. |
| 1.3.6.1.4.1.6876.100.1.0.80235 | NSXTHostNodeStatusDegradedEvent | Warning | NSX-T Host Transport Node Status is 'Degraded'. | NSX-T Host Transport Node Status is 'Degraded'. |
| 1.3.6.1.4.1.6876.100.1.0.80236 | NSXTHostNodeStatusUnknownEvent | Warning | NSX-T Host Transport Node Status is 'Unknown'. | NSX-T Host Transport Node Status is 'Unknown'. |
| 1.3.6.1.4.1.6876.100.1.0.80237 | NSXTEdgeNodePnicStatusDownEvent | Critical | NSX-T Edge Transport Node Pnic Status is 'Down'. | NSX-T Edge Transport Node Pnic Status is 'Down'. |
| 1.3.6.1.4.1.6876.100.1.0.80238 | NSXTEdgeNodePnicStatusDegradedEvent | Critical | NSX-T Edge Transport Node Pnic Status is 'Degraded'. | NSX-T Edge Transport Node Pnic Status is 'Degraded'. |
| 1.3.6.1.4.1.6876.100.1.0.80239 | NSXTEdgeNodePnicStatusUnknownEvent | Critical | NSX-T Edge Transport Node Pnic Status is 'Unknown'. | NSX-T Edge Transport Node Pnic Status is 'Unknown'. |
| 1.3.6.1.4.1.6876.100.1.0.80240 | NSXTEdgeNodeTunnelStatusDownEvent | Critical | NSX-T Edge Transport Node Tunnel Status is 'Down'. | NSX-T Edge Transport Node Tunnel Status is 'Down'. |
| 1.3.6.1.4.1.6876.100.1.0.80241 | NSXTEdgeNodeTunnelStatusDegradeEvent | Critical | NSX-T Edge Transport Node Tunnel Status is 'Degraded'. | NSX-T Edge Transport Node Tunnel Status is 'Degraded'. |
| 1.3.6.1.4.1.6876.100.1.0.80242 | NSXTEdgeNodeTunnelStatusUnknownEvent | Critical | NSX-T Edge Transport Node Tunnel Status is 'Unknown'. | NSX-T Edge Transport Node Tunnel Status is 'Unknown'. |
| 1.3.6.1.4.1.6876.100.1.0.80243 | NSXTEdgeNodeStatusDownEvent | Critical | NSX-T Edge Transport Node Status is 'Down'. | NSX-T Edge Transport Node Status is 'Down'. |
| 1.3.6.1.4.1.6876.100.1.0.80244 | NSXTEdgeNodeStatusDegradedEvent | Critical | NSX-T Edge Transport Node Status is 'Degraded'. | NSX-T Edge Transport Node Status is 'Degraded'. |
| 1.3.6.1.4.1.6876.100.1.0.80245 | NSXTEdgeNodeStatusUnknownEvent | Critical | NSX-T Edge Transport Node Status is 'Unknown'. | NSX-T Edge Transport Node Status is 'Unknown'. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80246 | NSXTHostNodeMgmtConnectivityStatusDownEvent | Warning | NSX-T Host Node has no manager connectivity | Desynchronization between NSX Manager's State of connectivity with Host Transport Nodes |
| 1.3.6.1.4.1.6876.100.1.0.80247 | NSXTEdgeNodeCtlrConnectivityStatusUnknownEvent | Critical | Controller connectivity for NSX-T Edge Node is Unknown. | NSX-T Edge Node Controller connectivity is Unknown. |
| 1.3.6.1.4.1.6876.100.1.0.80248 | NSXTHostNodeCtlrConnectivityStatusDownEvent | Warning | NSX-T Host Node has no controller connectivity | NSX-T Host Node is not able to communicate with any of the controllers. |
| 1.3.6.1.4.1.6876.100.1.0.80249 | NSXTHostNodeCtlrConnectivityStatusDegradedEvent | Warning | Controller connectivity degraded for NSX-T Host Node | NSX-T Host Node is not able to to communicate with one or more controllers. |
| 1.3.6.1.4.1.6876.100.1.0.80250 | NSXTHostNodeCtlrConnectivityStatusUnknownEvent | Warning | Controller connectivity for NSX-T Host Node is Unknown. | NSX-T Host Node Controller connectivity is Unknown. |
| 1.3.6.1.4.1.6876.100.1.0.80252 | NSXTLogicalSwitchAdminStatusDownEvent | Warning | NSX-T Logical Switch Admin Status is 'Down' | NSX-T Logical Switch Admin Status is 'Down' |
| 1.3.6.1.4.1.6876.100.1.0.80253 | NSXTLogicalPortOperationalStatusDownEvent | Critical | NSX-T Logical Port Operational Status is 'Down' | NSX-T Logical Port Operational Status is 'Down'. This could cause a communication failure between two virtual interfaces (VIFs) that are connected to the same logical switch, for example, you cannot ping one VM from another. |
| 1.3.6.1.4.1.6876.100.1.0.80254 | NSXTLogicalPortOperationalStatusUnknownEvent | Warning | NSX-T Logical Port Operational Status is 'Unknown' | NSX-T Logical Port Operational Status is 'Unknown'. This could cause a communication failure between two virtual interfaces (VIFs) that are connected to the same logical switch, for example, you cannot ping one VM from another. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80255 | NSXTComputeManagerConnectionStatusNotUpEvent | Warning | NSX-T Compute Manager Connection Status in not up | NSX-T Compute Manager Connection status is not up |
| 1.3.6.1.4.1.6876.100.1.0.80256 | NSXTClusterBackUpDisabledEvent | Warning | NSX-T Manager backup is not scheduled. | NSX-T Manager backup is not scheduled |
| 1.3.6.1.4.1.6876.100.1.0.80257 | NSXTDFWFirewallDisabledEvent | Critical | NSX-T DFW Firewall is deactivated. | Distributed Firewall is deactivated in the NSX-T Manager |
| 1.3.6.1.4.1.6876.100.1.0.80258 | NSXTLogicalPortReceivedPacketDropEvent | Warning | NSX-T Logical Port Received Packets are getting dropped. | Received packets are getting dropped on the NSX-T Logical Port and associated entities might get affected |
| 1.3.6.1.4.1.6876.100.1.0.80259 | NSXTLogicalPortTransmittedPacketDropEvent | Warning | NSX-T Logical Port Transmitted Packets are getting dropped. | Transmitted packets are getting dropped on the NSX-T Logical Port and associated entities might get affected |
| 1.3.6.1.4.1.6876.100.1.0.80260 | NSXTLogicalSwitchReceivedPacketDropEvent | Warning | NSX-T Logical Switch Received Packets are getting dropped | Received packets are getting dropped on the NSX-T Logical Switch and associated entities might get affected |
| 1.3.6.1.4.1.6876.100.1.0.80261 | NSXTLogicalSwitchTransmittedPacketDropEvent | Warning | NSX-T Logical Switch Transmitted Packets are getting dropped | Transmitted packets are getting dropped on the NSX-T Logical Switch and associated entities might get affected |
| 1.3.6.1.4.1.6876.100.1.0.80262 | NSXTRxPacketDropOnMPNicEvent | Warning | Received packets are dropping on NSX-T Management Node's network interface | Received packets are getting dropped on NSX-T Management Node's network interface. This may impact the network traffic related to NSX-T management cluster. |
| 1.3.6.1.4.1.6876.100.1.0.80263 | NSXTRxPacketDropOnEdgeTnNicEvent | Critical | Received packets are dropping on NSX-T Edge Node's network interface | Received packets are getting dropped on NSX-T Edge Node's network interface. This may impact the network traffic of edge cluster. |

|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80413 | NSXTMPNodeServiceNSXMessageBusStatusEvent | Warning | Message Bus Service has stopped running. | Message Bus Client Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80413 | NSXTMPNodeServiceNSXMessageBusStatusEvent | Warning | Message Bus Service has stopped | One of the Services of the NSX-T Management Node, namely Message Bus Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80414 | NSXTMPNodeServiceNSXPlatformClientStatusEvent | Warning | Platform Client Service has stopped running. | Platform Client Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80414 | NSXTMPNodeServiceNSXPlatformClientStatusEvent | Critical | Platform Client Service has stopped | One of the Services of the NSX-T Management Node, namely Platform Client Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80415 | NSXTMPNodeServiceNSXUpgradeAgentStatusEvent | Warning | Upgrade Agent Service has stopped running. | Upgrade Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80415 | NSXTMPNodeServiceNSXUpgradeAgentStatusEvent | Warning | Upgrade Agent Service has stopped | One of the Services of the NSX-T Management Node, namely Upgrade Agent Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80416 | NSXTMPNodeServiceNTPStatusEvent | Warning | NTP Service has stopped running. | NTP Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80416 | NSXTMPNodeServiceNTPStatusEvent | Critical | NTP Service has stopped | One of the Services of the NSX-T Management Node, namely NTP Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80417 | NSXTMPNodeServicePolicyStatusEvent | Warning | Policy Service has stopped running. | Policy Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80417 | NSXTMPNodeServicePolicyStatusEvent | Critical | Policy Service has stopped | One of the Services of the NSX-T Management Node, namely Policy Service has stopped running. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80418 | NSXTMPNodeServiceSearchStatusEvent | Warning | Search Service has stopped running. | Search Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80418 | NSXTMPNodeServiceSearchStatusEvent | Critical | Search Service has stopped | One of the Services of the NSX-T Management Node, namely Search Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80419 | NSXTMPNodeServiceSNMPStatusEvent | Warning | SNMP Service has stopped running. | SNMP Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80419 | NSXTMPNodeServiceSNMPStatusEvent | Warning | SNMP Service has stopped | One of the Services of the NSX-T Management Node, namely SNMP Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80420 | NSXTMPNodeServiceSSHStatusEvent | Warning | SSH Service has stopped running. | SSH Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80420 | NSXTMPNodeServiceSSHStatusEvent | Critical | SSH Service has stopped | One of the Services of the NSX-T Management Node, namely SSH Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80421 | NSXTMPNodeServiceSyslogStatusEvent | Warning | Syslog Service has stopped running. | Syslog Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80421 | NSXTMPNodeServiceSyslogStatusEvent | Critical | Syslog Service has stopped | One of the Services of the NSX-T Management Node, namely Syslog Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80422 | NSXTMPNodeServiceTelemetryStatusEvent | Warning | Telemetry Service has stopped running. | Telemetry Service status has turned to stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80422 | NSXTMPNodeServiceTelemetryStatusEvent | Warning | Telemetry Service has stopped | One of the Services of the NSX-T Management Node, namely Telemetry Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80423 | NSXTMPNodeServiceUIServiceStatusEvent | Warning | UI Service has stopped running. | UI Service status has turned to stopped. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80423 | NSXTMPNodeServiceUIServiceStatusEvent | Critical | UI Service has stopped | One of the Services of the NSX-T Management Node, namely UI Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80424 | NSXTMPNodeServiceClusterManagerStatusEvent | Critical | Cluster Manager Service has stopped | One of the Services of the NSX-T Management Node, namely Cluster Manager Service has stopped running. |
| 1.3.6.1.4.1.6876.100.1.0.80501 | vmwIndexerLagEvent | Critical | Indexer Lag Alert | Recent data is still being indexed. Search results may be inaccurate. |
| 1.3.6.1.4.1.6876.100.1.0.80502 | vmwIPFIXFlowDPPausedEvent | Critical | IPFIX Flow Data Source Paused alert | Ipfix Flow Data Source has been paused due to large number of flows. |
| 1.3.6.1.4.1.6876.100.1.0.80503 | vmwGridProcessingStoppedEvent | Critical | Grid Processing Stopped | Grid processing has stopped. |
| 1.3.6.1.4.1.6876.100.1.0.80504 | vmwUnableToSendEmailsEvent | Critical | Unable to Send Emails message | Unable to send email message. |
| 1.3.6.1.4.1.6876.100.1.0.80505 | vmwSMTPNotConfiguredEvent | Critical | SMTP Not Configured | SMTP Not Configured |
| 1.3.6.1.4.1.6876.100.1.0.80506 | vmwSNMPNotConfiguredEvent | Critical | SMTP Not Configured | No SNMP Targets are configured. |
| 1.3.6.1.4.1.6876.100.1.0.80507 | vmwReindexingInProgressEvent | Critical | Reindexing in Process | Data is currently being re-indexed. Search service will be available after this migration activity is complete. |
| 1.3.6.1.4.1.6876.100.1.0.80508 | vmwNodesVersionMismatchEvent | Critical | Nodes Version Mismatch | Nodes Version Mismatch detected |
| 1.3.6.1.4.1.6876.100.1.0.80509 | vmwNotAllServicesRunningEvent | Critical | Not All Services Running | One or more essential services are not running. |
| 1.3.6.1.4.1.6876.100.1.0.80510 | vmwNotAllServicesHealthyEvent | Critical | Not All Services Healthy | One or more essential services are not healthy. |
| 1.3.6.1.4.1.6876.100.1.0.80511 | vmwExpandPartitionFailedEvent | Critical | Expand Partition Failed | Failed to expand disk partition. |
| 1.3.6.1.4.1.6876.100.1.0.80512 | vmwDiskCleanupFailedEvent | Critical | Disk Cleanup Failed | Disk Cleanup service is unhealthy. |
| 1.3.6.1.4.1.6876.100.1.0.80513 | vmwVacuumFailedEvent | Critical | Vacuum Failed | PostgreSQL Vacuum service is unhealthy. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80514 | vmwConfigStoreCleanupFailedEvent | Critical | Config Store Cleanup Failed | Data Retention (Config Store Maintenance) service is unhealthy. |
| 1.3.6.1.4.1.6876.100.1.0.80515 | vmwHBaseRetentionToolFailedEvent | Critical | HBASE Retention Tool Failed | Data Retention (Metric Retention Configuration) service is unhealthy. |
| 1.3.6.1.4.1.6876.100.1.0.80516 | vmwMetricStoreUpdaterFailedEvent | Critical | Metric Store Updater Failed | Data Retention (Metric Store Maintenance) service is unhealthy. |
| 1.3.6.1.4.1.6876.100.1.0.80517 | vmwCollectorLagEvent | Critical | Collecter Lag | Last data collection on collector was more than threshold ago |
| 1.3.6.1.4.1.6876.100.1.0.80518 | vmwCollectionLagEvent | Critical | Collection Lag | Last data collection on data source was more than threshold ago |
| 1.3.6.1.4.1.6876.100.1.0.80519 | vmwGridProcessingLagEvent | Critical | Grid Processing Lag | Grid processing is lagging by more than threshold ago |
| 1.3.6.1.4.1.6876.100.1.0.80520 | vmwConnectionErorEvent | Critical | Connection Error | Error connecting to data source |
| 1.3.6.1.4.1.6876.100.1.0.80521 | vmwNodeNotActiveEvent | Critical | Node Not Active | Node Not Active |
| 1.3.6.1.4.1.6876.100.1.0.80522 | vmwHighDiskUtilizationEvent | Critical | High Disk Utilization | High Disk Utilization |
| 1.3.6.1.4.1.6876.100.1.0.80523 | vmwIndexingAbortedEvent | Critical | Indexing Aborted | Indexing Aborted |
| 1.3.6.1.4.1.6876.100.1.0.80524 | vmwUpgradeFailedEvent | Critical | Upgrade Failed | Upgrade Failed |
| 1.3.6.1.4.1.6876.100.1.0.80525 | vmwFlowProcessingSuspendedEvent | Critical | Flow Processing Suspended | Flow processing suspended |
| 1.3.6.1.4.1.6876.100.1.0.80526 | vmwLargeSdmsDroppedEvent | Critical | Data Processing Error | Large SDMS Dropped |
| 1.3.6.1.4.1.6876.100.1.0.80527 | vmwApplianceNotConfiguredEvent | Critical | Appliance Not Configured | Collector VM configuration incomplete. |
| 1.3.6.1.4.1.6876.100.1.0.80531 | vmwFdbConfigStoreCleanupFailedEvent | | FDB_CONFIG_STORE_CLEANUP_FAILED_EVENT | FDB Config Store Cleanup Failed |
| 1.3.6.1.4.1.6876.100.1.0.80531 | vmwDiskAllocationInsufficientEvent | Info | DISK_ALLOCATION_INSUFFICIENT_EVENT | Disk Not Configured |
| 1.3.6.1.4.1.6876.100.1.0.80601 | vmwFailedEvent | Critical | Data Source Failed | Data Source Failed |
| 1.3.6.1.4.1.6876.100.1.0.80602 | vmwTimeoutEvent | Critical | Data Source Timeout | Data Source Timeout |
| 1.3.6.1.4.1.6876.100.1.0.80603 | vmwConnectionRefusedEvent | Critical | Connection Refused | Connection Refused |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80605 | vmwIncorrectConnectionStringEvent | Critical | Incorrect Connection String | Incorrect Connection String |
| 1.3.6.1.4.1.6876.100.1.0.80606 | vmwInvalidCredentialsEvent | Critical | Invalid Credentials | Invalid Credentials |
| 1.3.6.1.4.1.6876.100.1.0.80608 | vmwUnknownHostEvent | Critical | Unknown Host | Unknown Host |
| 1.3.6.1.4.1.6876.100.1.0.80609 | vmwSNMPConnectionInvalidEvent | Critical | Invalid SNMP Connection | Invalid SNMP Connection |
| 1.3.6.1.4.1.6876.100.1.0.806100012 | vmwPwdAuthModeDisabledAristaEvent | Critical | Password Authentication Deactivated | Password Authentication Deactivated |
| 1.3.6.1.4.1.6876.100.1.0.806100018 | vmwUnsupportedNSXVersionEvent | Critical | Unsupported NSX Version | Unsupported NSX Version |
| 1.3.6.1.4.1.6876.100.1.0.80611 | vmwFailedCredsEncryptEvent | Critical | Credential Encryption Failed | Credential Encryption Failed |
| 1.3.6.1.4.1.6876.100.1.0.80612 | vmwPwdAuthModeDisabledEvent | Critical | Password Authentication Mode Deactivated | Password Authentication Mode Deactivated |
| 1.3.6.1.4.1.6876.100.1.0.80613 | vmwInsufficientPrivilegesEvent | Critical | Insufficient Privileges | Insufficient Privileges |
| 1.3.6.1.4.1.6876.100.1.0.8061313 | vmwFlowCollectionErrorEvent | Critical | Flow Collection Error | Flow Collection Error |
| 1.3.6.1.4.1.6876.100.1.0.8061314 | vmwAWSThrottlingExceptionEvent | Critical | AWS Throttling Exception | AWS Throttling Exception |
| 1.3.6.1.4.1.6876.100.1.0.8061315 | vmwAWSFlowLogAccessDeniedExceptionEvent | Critical | AWS Flow Log Access Denied Exception | AWS Flow Log Access Denied Exception. This alert is raised when user does not have necessary permissions required to collect flow logs. |
| 1.3.6.1.4.1.6876.100.1.0.80614 | vmwNotFoundEvent | Critical | Not Found Alert | Not Found |
| 1.3.6.1.4.1.6876.100.1.0.80616 | vmwInvalidConfigEvent | Critical | Invalid Data Source Config | Invalid Data Source Config |
| 1.3.6.1.4.1.6876.100.1.0.80617 | vmwWarnConfigEvent | Critical | Invalid Data Source Config | Invalid Data Source Config |
| 1.3.6.1.4.1.6876.100.1.0.80618 | vmwUnexpectedDSTypeOrVersionEvent | Critical | Unexpected Datasource Type or Version | Unexpected Datasource Type or Version |
| 1.3.6.1.4.1.6876.100.1.0.80619 | vmwNSXControllerNotFoundEvent | Critical | NSX Controller Not Found | NSX Controller Not Found |
| 1.3.6.1.4.1.6876.100.1.0.80620 | vmwHostNotReachableEvent | Critical | Host Not Reachable | Host Not Reachable |
| 1.3.6.1.4.1.6876.100.1.0.80621 | vmwInvalidResponseFromDatasourceEvent | Critical | Invalid Response From Data Source | Invalid Response From Data Source |
| 1.3.6.1.4.1.6876.100.1.0.80622 | vmwDataProviderNotRunningEvent | Critical | Data Source Not Running | Data Source Not Running |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80623 | vmwPrimaryNSXNotAddedEvent | Critical | Primary NSX Not Added | Primary NSX Not Added |
| 1.3.6.1.4.1.6876.100.1.0.80624 | vmwHostnameResolutionErrorEvent | Critical | Hostname Resolution Error | Hostname Resolution Error |
| 1.3.6.1.4.1.6876.100.1.0.80625 | vmwNumVMsOrHostsNotFoundEvent | Critical | Number of Vms or Hosts Not Found | Number of Vms or Hosts Not Found |
| 1.3.6.1.4.1.6876.100.1.0.80626 | vmwNSXIPFIXStatusMismatchEvent | Critical | NSX IPFIX Status Mismatch | NSX IPFIX Status Mismatch |

| 1.3.6.1.4.1.6876.100.1.0.80628 | vmwNotEmptyNodeEvent | Critical | Not Empty Node Alert | Not Empty Node |
| 1.3.6.1.4.1.6876.100.1.0.80629 | vmwUnsupportedNSXTVersionEvent | Critical | Unsupported NSXT Version | Unsupported NSXT Version |
| 1.3.6.1.4.1.6876.100.1.0.80630 | vmwComputeManagersNotFoundEvent | Critical | Compute Managers Not Found | Compute Managers Not Found |
| 1.3.6.1.4.1.6876.100.1.0.80631 | vmwComputeManagersNotAddedEvent | Critical | Compute Managers Not Added | Compute Managers Not Added |
| 1.3.6.1.4.1.6876.100.1.0.80632 | vmwUnsupportedLogInsightVersionEvent | Critical | VCF Operations for logs version not supported | VMware VCF Operations for logs version not supported |
| 1.3.6.1.4.1.6876.100.1.0.80633 | vmwUnsupportedVRNIContentPackVersionEvent | Critical | VCF Operations for networks Content Pack version not supported | VCF Operations for networks Content Pack version not supported |
| 1.3.6.1.4.1.6876.100.1.0.80634 | vmwVRNIContentPackNotInstalledEvent | Critical | VCF Operations for networks Content Pack not found in VCF Operations for logs | VCF Operations for networks Content Pack not found in VCF Operations for logs |
| 1.3.6.1.4.1.6876.100.1.0.80635 | vmwWebhookNotEnabledOnAlertEvent | Critical | Webhook not enabled on a VCF Operations for networks alert | Webhook not enabled for one or more alerts of VCF Operations for networks Content Pack in VCF Operations for logs |
| 1.3.6.1.4.1.6876.100.1.0.80636 | vmwIncorrectWebhookConfiguredOnAlertEvent | Critical | Incorrect webhook URL configured on a VCF Operations for logs alert | Incorrect webhook configuration found for one or more alerts of VCF Operations for networks Content Pack in VCF Operations for logs |
| 1.3.6.1.4.1.6876.100.1.0.80637 | vmwWebhookNotRunningEvent | Critical | Webhook is not running on the Collector(Proxy) VM | Webhook is not running on the Collector(Proxy) VM |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80638 | vmwInfobloxRecordLimitExceededEvent | Critical | The number of records from Infoblox exceeds current limit | The number of records from Infoblox exceeds current limit |
| 1.3.6.1.4.1.6876.100.1.0.80639 | vmwIncorrectInfobloxCredentialEvent | Critical | Incorrect Infoblox Credentials | Infoblox credentials are invalid or the user does not have the "API Privilege" to access Infoblox data |
| 1.3.6.1.4.1.6876.100.1.0.80640 | vmwUnsupportedInfobloxVersionEvent | Critical | Unsupported Infoblox Version | The version of NIOS is not supported. |
| 1.3.6.1.4.1.6876.100.1.0.80641 | vmwUnknownInfobloxVersionEvent | Critical | Unknown Infoblox Version | The version of NIOS cannot be determined. |
| 1.3.6.1.4.1.6876.100.1.0.80642 | vmwNoDVSAvailableEvent | Critical | IPFIX cannot be enabled | IPFIX cannot be enabled since no DVS found |
| 1.3.6.1.4.1.6876.100.1.0.80643 | vmwVCNotOnSameProxyEvent | Critical | NSX Manager and the vCenter DataSource not on the same Collector VM | NSX Manager and the associated vCenter DataSources is not on the same Collector VM. |
| 1.3.6.1.4.1.6876.100.1.0.80644 | vmwNSXTIPFixNoCollectorProfileEvent | Critical | NSX-T IPFIX No Collector Profile | NSXT IPFIX No Collector Profile |
| 1.3.6.1.4.1.6876.100.1.0.80645 | vmwNSXTIPFixNoNewCollectorProfileCanBeAddedEvent | Critical | NSX-T IPFIX no new Collector Profile can be added | NSXT IPFIX no new Collector Profile can be added |
| 1.3.6.1.4.1.6876.100.1.0.80646 | vmwNSXTIPFixNoIPFixProfileEvent | Critical | NSX-T IPFIX No Ipfix Profile | NSXT IPFIX No Ipfix Profile |
| 1.3.6.1.4.1.6876.100.1.0.80647 | vmwNSXTIPFixIPFixProfilePriorityNotZeroEvent | Critical | NSX-T IPFIX Ipfix Profile Priority not zero | NSXT IPFIX Ipfix Profile Priority not zero |
| 1.3.6.1.4.1.6876.100.1.0.80648 | vmwNSXTIPFixCollectorAndIPFixProfileMismatchEvent | Critical | NSX-T IPFIX Collector and Ipfix Profile Mismatch | NSXT IPFIX Collector and Ipfix Profile Mismatch |
| 1.3.6.1.4.1.6876.100.1.0.80649 | vmwNSXTIPFixPortIncorrectEvent | Critical | NSX-T IPFIX Collector Port Incorrect | Collector Port in Collector Profile is incorrect |
| 1.3.6.1.4.1.6876.100.1.0.80650 | vmwNSXTIPFixDFWStatusNotEnabledEvent | Critical | NSX-T IPFIX DFW is not Enabled | NSX-T IPFIX DFW is not Enabled |
| 1.3.6.1.4.1.6876.100.1.0.80651 | vmwPolicyManagerNoDfwIPFixProfile | Critical | DFW IPFIX Profile absent on NSX Policy Manager | DFW IPFIX Profile is not found on NSX Policy Manager |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80652 | vmwPolicyManagerVrniDfwIPFixCollectorAbsent | Critical | VCF Operations for networks IPFIX Collector configuration is absent on NSX Policy Manager | VCF Operations for networks IPFIX Collector IP and port are not present in DFW IPFIX Collector Profile on NSX Policy Manager. |
| 1.3.6.1.4.1.6876.100.1.0.80653 | vmwDatasourceIdentificationChangedEvent | Info | Identity information for Data Source changed | The data source identity information such as certificate or the key has changed. |
| 1.3.6.1.4.1.6876.100.1.0.80654 | vmwPKSKubernetesUnknownHostEvent | Critical | Kubernetes Cluster API Servers not reachable | One or more Kubernetes Cluster's Kube Config file in Tanzu Kubernetes Grid Integrated Edition is not valid. |
| 1.3.6.1.4.1.6876.100.1.0.80655 | vmwKubernetesInsufficientPrivilegesEvent | Critical | Kubernetes Cluster Service Accounts do not have sufficient privileges | One or more Kubernetes Cluster Service Accounts do not have sufficient privileges. |
| 1.3.6.1.4.1.6876.100.1.0.80657 | vmwUANIFileNotProvidedEvent | Critical | File required by Generic Routers & Switches Data Source not provided | File required by Generic Routers & Switches Data Source not provided |
| 1.3.6.1.4.1.6876.100.1.0.80658 | vmwUANIFileDoesNotExistEvent | Critical | File required by Generic Routers & Switches Data Source does not exist | File required by Generic Routers & Switches Data Source does not exist |
| 1.3.6.1.4.1.6876.100.1.0.80659 | vmwNSXTLatencyNotEnabledEvent | Critical | NSXT_LATENCY_NOT_ENABLED_EVENT | NSX-T latency collection is not enabled |
| 1.3.6.1.4.1.6876.100.1.0.80660 | vmwNSXTLatencyMoreBFDProfileEvent | | NSXT_LATENCY_MORE_BFD_PROFILE_EVENT | |
| 1.3.6.1.4.1.6876.100.1.0.80662 | vmwNSXTLatencyCollectorMismatchEvent | Critical | NSXT_LATENCY_COLLECTOR_MISMATCH_EVENT | NSX-T latency collector not configured |
| 1.3.6.1.4.1.6876.100.1.0.80663 | vmwBigIpInsufficientShellAccessEvent | Critical | BIGIP_INSUFFICIENT_SHELL_ACCESS_EVENT | No access to shell |
| 1.3.6.1.4.1.6876.100.1.0.80664 | vmwBigIpInsufficientPartitionAccessEvent | Critical | BIGIP_INSUFFICIENT_PARTITION_ACCESS_EVENT | Insufficient Partition Access |
| 1.3.6.1.4.1.6876.100.1.0.80665 | vmwBigIpInsufficientRoleEvent | Critical | BIGIP_INSUFFICIENT_ROLE_EVENT | Insufficient Role |
| 1.3.6.1.4.1.6876.100.1.0.90001 | vmwVeloCloudEdgeDownEvent | Warning | VeloCloud Edge is not healthy | Edge State of VeloCloud Edge is not connected. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.90002 | vmwVeloCloudLinkDownEvent | Warning | VeloCloud Link is not healthy | Link State of VeloCloud Edge is not connected. |
| 1.3.6.1.4.1.6876.100.1.0.90003 | vmwVeloCloudEdgeL7ApplicationLostPacketEvent | Critical | Packet Drop Alert | Packet Drop Alert on Edge for Application. This is raised when the total packets are more than 1000 and packet drop percentage is greater than 3% and the edge QoE value is less than 9. |
| 1.3.6.1.4.1.6876.100.1.0.90004 | vmwVeloCloudEdgeL7ApplicationRetransmittedPacketEvent | Warning | Retransmitted Packet Alert. | Retransmitted Packet Alert on Edge for Application. This alert is raised when total packets are more than 1000 and retransmitted packet percentage is greater than 5% and the edge QoE value is less than 9. |
| 1.3.6.1.4.1.6876.100.1.0.90005 | vmwVeloCloudLinkLostPacketEventTx | Critical | VeloCloud Link Upstream Packet Loss exceeds threshold. | VeloCloud Link Tx Packet Loss. |
| 1.3.6.1.4.1.6876.100.1.0.90006 | vmwVeloCloudEdgeLocationNotSetEvent | Info | VeloCloud Edge location is not set. | VeloCloud Edge location is not set. |
| 1.3.6.1.4.1.6876.100.1.0.90007 | vmwVeloCloudLinkDegradedVoiceQoeEvent | Critical | VeloCloud Link Voice QOE degraded. | VeloCloud Link Voice QOE Degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90008 | vmwVeloCloudLinkDegradedVideoQoeEvent | Critical | VeloCloud Link Video QOE degraded. | VeloCloud Link Video QOE Degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90009 | vmwVeloCloudLinkDegradedTransQoeEvent | Critical | VeloCloud Link Transactional QOE degraded. | VeloCloud Link Transactional QOE Degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90010 | vmwVeloCloudEdgeDegradedVoiceQoeEvent | Critical | VeloCloud Edge Voice QOE degraded. | VeloCloud Edge Voice QOE degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90011 | vmwVeloCloudEdgeDegradedVideoQoeEvent | Critical | VeloCloud Edge Video QOE degraded. | VeloCloud Edge Video QOE degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90012 | vmwVeloCloudEdgeDegradedTransQoeEvent | Critical | VeloCloud Edge Transactional QOE degraded. | VeloCloud Edge Transactional QOE degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90013 | vmwVeloCloudLinkLostPacketEventRx | Critical | VeloCloud Link Downstream Packet Loss exceeds threshold. | VeloCloud Link RX Packet Loss. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.90014 | vmwVeloCloudTunnelDegradedVoiceQoeEvent | Critical | VeloCloud Tunnel Voice QOE Degraded. | VeloCloud Tunnel Voice QOE Degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90015 | vmwVeloCloudTunnelDegradedVideoQoeEvent | Critical | VeloCloud Tunnel Video QOE Degraded. | VeloCloud Tunnel Video QOE Degraded. |
| 1.3.6.1.4.1.6876.100.1.0.90016 | vmwVeloCloudTunnelDegradedTransQoeEvent | Critical | VeloCloud Tunnel Transaction QOE Degraded. | VeloCloud Tunnel Transaction QOE Degraded. |
| 1.3.6.1.4.1.6876.100.1.0.974 | vmwNSXIApplianceAvailableEvent | Info | Security Intelligence Appliance Available | This event is raised when VCF Operations for networks detects that Security Intelligence appliance is available for an NSX data source. |
| 1.3.6.1.4.1.6876.100.1.0.975 | vmwNSXISubscriptionCreateFailedEvent | Critical | Failed to enable data collection from Security Intelligence | This event is raised when VCF Operations for networks is unable to create a subscription with the Security Intelligence Appliance. |
| 1.3.6.1.4.1.6876.100.1.0.976 | vmwNSXISubscriptionDeleteFailedEvent | Critical | Security Intelligence cleanup failed | This event is raised when VCF Operations for networks is unable to delete a subscription with the Security Intelligence Appliance. |
| 1.3.6.1.4.1.6876.100.1.0.977 | vmwNSXISubscriptionUpdateFailedEvent | Critical | Failed to initiate data collection from Security Intelligence | This event is raised when VCF Operations for networks is unable to update a subscription with the Security Intelligence Appliance. |
| 1.3.6.1.4.1.6876.100.1.0.978 | vmwNSXISSLHandshakeFailedEvent | Critical | Security Intelligence SSL Handshake Failed | This event is raised when the SSL Handshake between VCF Operations for networks Collector and Security Intelligence Appliance fails. |
| 1.3.6.1.4.1.6876.100.1.0.80539 | UNABLE_TO_SEND_SNMP_TRAPS_EVENT | Critical | Unable to Send SNMP Traps | Unable to Send SNMP Traps. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80540 | STREAM_PROCESSING_FAILED_EVENT | Critical | Realtime stream processing failure | Real-time stream processing has failed. |
| 1.3.6.1.4.1.6876.100.1.0.20018 | VMotionEvent | Info | VMotion | This alert is raised when a VM moves from one host to another through live migration. |
| 1.3.6.1.4.1.6876.100.1.0.20018 | VMCSDDCTGWConnectivityFailedEvent | Critical | VMC SDDC VTGW Connectivity Failure | This alert is raised when SDDC within SDDC Group loses connectivity with VTGW |
| 1.3.6.1.4.1.6876.100.1.0.110014 | HSRPConfigurationEvent | Critical | HSRP/VRRP Configuration Error | Identifies HSRP/VRRP configuration errors in the network. |
| 1.3.6.1.4.1.6876.100.1.0.90502 | HcxIXApplianceEncryptionTunnelStatusEvent | Critical | Hybrid Interconnect Service Encryption Tunnel Status Alert | Hybrid Interconnect Service Encryption Tunnel Status is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90503 | HcxNEServiceStatusEvent | Critical | HCX Network Extension Service Status Alert | Network Extension Service is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90504 | HcxNEApplianceEncryptionTunnelStatusEvent | Critical | Network Extension Service Encryption Tunnel Status Alert | Network Extension Service Encryption Tunnel Status is not up |
| 1.3.6.1.4.1.6876.100.1.0.90505 | HcxIXApplianceServicePipelineStatusEvent | Critical | Hybrid Interconnect Service Pipeline Status Alert | Hybrid Interconnect Service Pipeline Status is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90506 | HcxNEApplianceServicePipelineStatusEvent | Critical | Network Extension Service Pipeline Status Alert | Network Extension Service Pipeline Status is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90507 | HcxIXApplianceServiceTransportStatusEvent | Critical | Hybrid Interconnect Service Transport Status Alert | Hybrid Interconnect Service Transport Status is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90508 | HcxNEApplianceServiceTransportStatusEvent | Critical | Network Extension Service Transport Status Alert | Network Extension Service Transport Status is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90509 | HcxIXApplianceServiceSystemStateEvent | Critical | Hybrid Interconnect Service System State Alert | Hybrid Interconnect Service System State is not good. |
| 1.3.6.1.4.1.6876.100.1.0.90510 | HcxNEApplianceServiceSystemStateEvent | Critical | Network Extension Service System State Alert | Network Extension Service System State is not good. |
| 1.3.6.1.4.1.6876.100.1.0.90512 | HcxBMServiceStatusEvent | Critical | HCX Bulk Migration Service Status Alert | Bulk Migration Service is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90513 | HcxVMotionServiceStatusEvent | Critical | HCX VMotion Service Status Alert | VMotion Service is not up. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.90514 | HcxIXServiceNotRunningEvent | Critical | Hybrid Interconnect Service Not Running Alert | Hybrid Interconnect Service is not running. |
| 1.3.6.1.4.1.6876.100.1.0.90515 | HcxNEServiceNotRunningEvent | Critical | Network Extension Service Not Running Alert | Network Extension Service is not running. |
| 1.3.6.1.4.1.6876.100.1.0.90516 | HcxWanOptServiceNotRunningEvent | Critical | WAN Optimisation Service Not Running Alert | WAN Optimisation Service is not running |
| 1.3.6.1.4.1.6876.100.1.0.80542 | CHANGE_EVENTS_DROPPED_EVENT | Warning | Realtime Processing Suppressed | This alerts is raised when realtime processing has stopped due to high system load. Here, some updates can be delayed. |
| 1.3.6.1.4.1.6876.100.1.0.80636 | INCORRECT_WEBHOOK_CONFIGURED_ON_ALERT_EVENT | Critical | Incorrect webhook URL configured on a VCF Operations for logs alert | Incorrect webhook configuration found for one or more alerts of VCF Operations for networks Content Pack in VCF Operations for logs. |
| 1.3.6.1.4.1.6876.100.1.0.80632 | UNSUPPORTED_LOG_INSIGHT_VERSION_EVENT | Critical | VCF Operations for logs version not supported | VCF Operations for logs version is not supported. |
| 1.3.6.1.4.1.6876.100.1.0.80633 | UNSUPPORTED_vRNI_CONTENT_PACK_VERSION_EVENT | Critical | VCF Operations for networks Content Pack version not supported | VCF Operations for networks Content Pack version is not supported. |
| 1.3.6.1.4.1.6876.100.1.0.80635 | WEBHOOK_NOT_ENABLED_ON_ALERT_EVENT | Critical | Webhook not enabled on a Operations for Networks alert | Webhook not enabled for one or more alerts of VCF Operations for networks Content Pack in VCF Operations for logs. |
| 1.3.6.1.4.1.6876.100.1.0.80637 | WEBHOOK_NOT_RUNNING_EVENT | Critical | Webhook is not running on the Collector(Proxy) VM | Webhook is not running on the Collector(Proxy) VM. |
| 1.3.6.1.4.1.6876.100.1.0.80634 | vRNI_CONTENT_PACK_NOT_INSTALLED_EVENT | Critical | VCF Operations for networks Content Pack not found in VCF Operations for logs | VCF Operations for networks Content Pack not found in VCF Operations for logs. |

| OID | Alert Parameter Name | Default Severity | UI Name | Alert Name |
|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80050 | PanLogInsightDroppedFlowEvent | Critical | Dropped Flows Detected on Palo Alto Device | Dropped flows are detected on Palo Alto device through VCF Operations for logs. |
| 1.3.6.1.4.1.6876.100.1.0.80274 | NSXTRouterInterfaceRPFPacketDropEvent | Warning | RPF Packets are getting dropped at NSX-T Router interface | RPF drop ratio exceeded 1% |
| 1.3.6.1.4.1.6876.100.1.0.80543 | HIGH_DISK_IO_UTILIZATION_EVENT | Critical | High Disk IO Utilization | High disk imput/ output utilization. |
| 1.3.6.1.4.1.6876.100.1.0.80051 | CPLogInsightDroppedFlowEvent | Critical | Dropped Flows Detected on Check Point Device | Dropped flows are detected on Check Point device through VCF Operations for logs. |
| 1.3.6.1.4.1.6876.100.1.0.90517 | HcxApplianceAllTunnelDownEvent | Critical | All tunnels down on HCX Appliance Alert | No tunnels are in working state on Hcx Appliance. |
| 1.3.6.1.4.1.6876.100.1.0.90519 | HCX MTU Mismatch Alert | Warning | HCX MTU Mismatch Alert | This alert is raised when the uplink networks for a service mesh have different MTU values. |
| 1.3.6.1.4.1.6876.100.1.0.90518 | HcxConnectionRuleViolationEvent | Warning | HCX Connection Rule Firewall Rule Violated Alert | This alert is raised when the VMware HCX connection rules violate the firewall rules of a datacenter. |
| 1.3.6.1.4.1.6876.100.1.0.90511 | HcxWanOptServiceStatusEvent | Critical | HCX WAN Optimization Service Status Alert | VMware WAN optimization is not up. |
| 1.3.6.1.4.1.6876.100.1.0.90520 | HcxApplianceUnhealthyTunnelsEvent | Warning | Unhealthy tunnels on HCX Appliance | A few tunnels on HCX Appliance are unhealthy. |
| 1.3.6.1.4.1.6876.100.1.0.90521 | HcxManagerVersionMismatchEvent | Critical | Version mismatch between paired HCX Managers | The paired HCX Managers are running different software versions. |
| 1.3.6.1.4.1.6876.100.1.0.90522 | HcxApplianceVersionMismatchEvent | Critical | Version mismatch between paired HCX Appliances | The paired HCX Appliances are running different software versions. |
| 1.3.6.1.4.1.6876.100.1.0.80275 | NSXTIPFixMultipleCollectorConfigurationEvent | Warning | Multiple collectors configured in the NSX Policy DFW IPFIX Collector Profile. | Multiple collectors are configured in the NSX Policy DFW IPFIX Collector Profile. |

## NSX-T Events

VCF Operations for networks raises several self-computed NSX-T alerts. In addition, all NSX-T generated system alerts (for NSX-T versions 2.2 to 2.5) and NSX-T Alarms (for NSX-T version 3.0 onwards) are also visible in VCF Operations for networks.

**Note:**
Starting from 6.3 release, a few events are optimized for quick notification and are delivered under 5 minutes. See the Optimized for quick notification column in the table.

**Table 1315: VCF Operations for networks Computed NSX-T Events**

| OID | Event Name | Default Severity | UI Name | Description | Optimized for quick notification? |
|---|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.40000 | SwitchPortRxNetworkUsageThresholdExceededEvent | Warning | PNIC Rx Network Utilization is high | PNIC utilization exceeds the threshold value of 75%. | No |
| 1.3.6.1.4.1.6876.100.1.0.40001 | vmwCriticalHostNotAccessibleEvent | Critical | Host with Infrastructure VMs cannot be accessed | Host with Infrastructure VMs cannot be accessed | No |
| 1.3.6.1.4.1.6876.100.1.0.40002 | SwitchPortTxNetworkUsageThresholdExceededEvent | Warning | PNIC Tx Network Utilization is high | PNIC utilization exceeds the threshold value of 75%. | No |
| 1.3.6.1.4.1.6876.100.1.0.40003 | SwitchPortRxNetworkUsageThresholdExceededCriticalEvent | Critical | PNIC Rx Network Utilization is high | PNIC utilization exceeds the threshold value of 90%. | No |
| 1.3.6.1.4.1.6876.100.1.0.40004 | SwitchPortTxNetworkUsageThresholdExceededCriticalEvent | Critical | PNIC Tx Network Utilization is high | PNIC utilization exceeds the threshold value of 90%. | No |
| 1.3.6.1.4.1.6876.100.1.0.40005 | ManagementHostHighCPUUsageEvent | Warning | Management Host CPU Usage Event | Host CPU utilization exceeds the threshold value of 75%. | No |
| 1.3.6.1.4.1.6876.100.1.0.40006 | ManagementHostHighCPUUsageCriticalEvent | Critical | Management Host CPU Usage Critical Event | Host CPU utilization exceeds the threshold value of 90%. | No |
| 1.3.6.1.4.1.6876.100.1.0.40007 | HostUnHealthyEvent | Critical | Host is not healthy | Host is not healthy | No |
| 1.3.6.1.4.1.6876.100.1.0.40008 | FileSystem Disk Available of NSX Controller is Low | Critical | FileSystem Disk Available of NSX Controller is Low | NSX Controller file system disk available percentage less than threshold value. | No |
| 1.3.6.1.4.1.6876.100.1.0.40011 | EdgeVmVnicRxPacketDropEvent | Critical | Receive packets are getting dropped on the VNIC of Edge VM. | Packets are getting dropped on the VNIC of Edge VM. This may impact the network traffic related to management nodes. | No |

| OID | Event Name | Default Severity | UI Name | Description | Optimized for quick notification? |
|---|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.40012 | EdgeVmVnicTxPacketDropEvent | Critical | Transmit packets are getting dropped on the VNIC of Edge VM. | Packets are getting dropped on the VNIC of Edge VM. This may impact the network traffic related to management nodes. | No |
| 1.3.6.1.4.1.6876.100.1.0.40013 | ManagementHostPnicRxPacketDropEvent | Critical | Receive packets are getting dropped on the PNIC of the management host. | Packets are getting dropped on the pNIC of the management host. This may impact the network traffic related to management nodes. | No |
| 1.3.6.1.4.1.6876.100.1.0.40014 | ManagementHostPnicTxPacketDropEvent | Critical | Transmit packets are getting dropped on the PNIC of the management host. | Packets are getting dropped on the pNIC of the management host. This may impact the network traffic related to management nodes. | No |
| 1.3.6.1.4.1.6876.100.1.0.80205 | NSXTNoUplinkConnectivityEvent | Warning | NSX-T Tier-1 logical router disconnect event | NSX-T Tier-1 logical router is disconnected from Tier-0 router. Networks under this router are not reachable from outside and vice versa. | No |
| 1.3.6.1.4.1.6876.100.1.0.80206 | NSXTRoutingAdvertisementEvent | Warning | Routing advertisement deactivated | Routing advertisement is deactivated for NSX-T Tier-1 logical router. Networks under this router are not reachable from outside. | No |
| 1.3.6.1.4.1.6876.100.1.0.80207 | NSXTManagerConnectivityDownEvent | Critical | NSX-T Edge Node has no manager connectivity | NSX-T Edge Node has lost manager connectivity. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80208 | NSXTControllerConnectivityDegradedEvent | Warning | Controller connectivity degraded for NSX-T Edge Node | NSX-T Edge Node is not able to communicate with one or more controllers. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80209 | NSXTControllerConnectivityDownEvent | Critical | NSX-T Edge Node has no controller connectivity | NSX-T Edge Node is not able to communicate with any of the controllers. | Yes |

| OID | Event Name | Default Severity | UI Name | Description | Optimized for quick notification? |
|---|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80210 | NSXTMtuMismatchEvent | Warning | MTU mismatch between NSX-T Tier-0 and uplink switch/router | The MTU configured on interfaces of Tier-0 logical router does not match with the interfaces of uplink switch/ router from same L2 network. This can impact the network performance. | No |
| 1.3.6.1.4.1.6876.100.1.0.80211 | NSXTExcludedVmFlowEvent | Info | One or More VMs excluded from NSX-T DFW Firewall. | One or more VMs are not protected by NSX-T DFW firewall. VCF Operations for networks will not receive IPFIX flows for these VMs. | No |
| 1.3.6.1.4.1.6876.100.1.0.80212 | NSXTDoubleVlanTaggingEvent | Warning | Uplink Vlan misconfiguration | Communication is disrupted because VLAN on uplink port of Tier 0 router is different than VLAN on the external gateway. | No |
| 1.3.6.1.4.1.6876.100.1.0.80213 | NSXTNoTzAttachedOnTnEvent | Warning | No transport zone is attached to the transport node. | No transport zone attached to the transport node. VMs might lose connectivity because of this. | No |
| 1.3.6.1.4.1.6876.100.1.0.80214 | NSXTVtepDeleteEvent | Warning | No VTEP available on the transport node. | All vteps are deleted from the transport node. VMs might lose connectivity because of this. | No |
| 1.3.6.1.4.1.6876.100.1.0.80225 | NSXTControllerNodeToControlClusterConnectivityEvent | Critical | NSX-T controller node has no control cluster connectivity | NSX-T controller node has lost control cluster connectivity. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80226 | NSXTControllerNodeToMgmtPlaneConnectivityEvent | Critical | NSX-T controller node has no management plane connectivity | NSX-T controller node has lost management plane connectivity. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80227 | NSXTMPNodeToMgmtClusterConnectivityEvent | Critical | NSX-T management node has no management cluster connectivity | NSX-T management node has lost management cluster connectivity. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80246 | NSXTHostNodeMgmtConnectivityStatusDownEvent | Warning | NSX-T Host Node has no manager connectivity | Desynchronization between NSX Manager's State of connectivity with Host Transport Nodes | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80247 | NSXTEdgeNodeCtlrConnectivityStatusUnknownEvent | Critical | Controller connectivity for NSX-T Edge Node is Unknown. | NSX-T Edge Node Controller connectivity is Unknown. | Yes |

| OID | Event Name | Default Severity | UI Name | Description | Optimized for quick notification? |
|---|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80248 | NSXTHostNodeCtlrConnectivityStatusDownEvent | Warning | NSX-T Host Node has no controller connectivity | NSX-T Host Node is not able to communicate with any of the controllers. | No |
| 1.3.6.1.4.1.6876.100.1.0.80249 | NSXTHostNodeCtlrConnectivityStatusDegradedEvent | Warning | Controller connectivity degraded for NSX-T Host Node | NSX-T Host Node is not able to to communicate with one or more controllers. | No |
| 1.3.6.1.4.1.6876.100.1.0.80250 | NSXTHostNodeCtlrConnectivityStatusUnknownEvent | Warning | Controller connectivity for NSX-T Host Node is Unknown. | NSX-T Host Node Controller connectivity is Unknown. | No |
| 1.3.6.1.4.1.6876.100.1.0.80228 | NSXTHostNodePnicStatusDownEvent | Warning | NSX-T Host Transport Node Pnic Status is 'Down'. | NSX-T Host Transport Node Pnic Status is 'Down'. | No |
| 1.3.6.1.4.1.6876.100.1.0.80229 | NSXTHostNodePnicStatusDegradedEvent | Warning | NSX-T Host Transport Node Pnic Status is 'Degraded' | NSX-T Host Transport Node Pnic Status is 'Degraded'. | No |
| 1.3.6.1.4.1.6876.100.1.0.80230 | NSXTHostNodePnicStatusUnknownEvent | Warning | NSX-T Host Transport Node Pnic Status is 'Unknown'. | NSX-T Host Transport Node Pnic Status is 'Unknown'. | No |
| 1.3.6.1.4.1.6876.100.1.0.80237 | NSXTEdgeNodePnicStatusDownEvent | Critical | NSX-T Edge Transport Node Pnic Status is 'Down'. | NSX-T Edge Transport Node Pnic Status is 'Down'. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80238 | NSXTEdgeNodePnicStatusDegradedEvent | Critical | NSX-T Edge Transport Node Pnic Status is 'Degraded'. | NSX-T Edge Transport Node Pnic Status is 'Degraded'. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80239 | NSXTEdgeNodePnicStatusUnknownEvent | Critical | NSX-T Edge Transport Node Pnic Status is 'Unknown'. | NSX-T Edge Transport Node Pnic Status is 'Unknown'. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80231 | NSXTHostNodeTunnelStatusDownEvent | Warning | NSX-T Host Transport Node Tunnel Status is 'Down'. | NSX-T Host Transport Node Tunnel Status is 'Down'. | No |
| 1.3.6.1.4.1.6876.100.1.0.80232 | NSXTHostNodeTunnelStatusDegradedEvent | Warning | NSX-T Host Transport Node Tunnel Status is 'Degraded'. | NSX-T Host Transport Node Tunnel Status is 'Degraded'. | No |
| 1.3.6.1.4.1.6876.100.1.0.80233 | NSXTHostNodeTunnelStatusUnknownEvent | Warning | NSX-T Host Transport Node Tunnel Status is 'Unknown'. | NSX-T Host Transport Node Tunnel Status is 'Unknown'. | No |
| 1.3.6.1.4.1.6876.100.1.0.80240 | NSXTEdgeNodeTunnelStatusDownEvent | Critical | NSX-T Edge Transport Node Tunnel Status is 'Down'. | NSX-T Edge Transport Node Tunnel Status is 'Down'. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80241 | NSXTEdgeNodeTunnelStatusDegradeEvent | Critical | NSX-T Edge Transport Node Tunnel Status is 'Degraded'. | NSX-T Edge Transport Node Tunnel Status is 'Degraded'. | Yes |

| OID | Event Name | Default Severity | UI Name | Description | Optimized for quick notification? |
|---|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80256 | NSXTClusterBackUpDisabledEvent | Warning | NSX-T Manager backup is not scheduled. | NSX-T Manager backup is not scheduled | No |
| 1.3.6.1.4.1.6876.100.1.0.80257 | NSXTDFWFirewallDisabledEvent | Critical | NSX-T DFW Firewall is deactivated. | Distributed Firewall is deactivated in the NSX-T Manager | No |
| 1.3.6.1.4.1.6876.100.1.0.80258 | NSXTLogicalPortReceivedPacketDropEvent | Warning | NSX-T Logical Port Received Packets are getting dropped. | Received packets are getting dropped on the NSX-T Logical Port and associated entities might get affected | No |
| 1.3.6.1.4.1.6876.100.1.0.80259 | NSXTLogicalPortTransmittedPacketDropEvent | Warning | NSX-T Logical Port Transmitted Packets are getting dropped. | Transmitted packets are getting dropped on the NSX-T Logical Port and associated entities might get affected | No |
| 1.3.6.1.4.1.6876.100.1.0.80260 | NSXTLogicalSwitchReceivedPacketDropEvent | Warning | NSX-T Logical Switch Received Packets are getting dropped | Received packets are getting dropped on the NSX-T Logical Switch and associated entities might get affected | No |
| 1.3.6.1.4.1.6876.100.1.0.80261 | NSXTLogicalSwitchTransmittedPacketDropEvent | Warning | NSX-T Logical Switch Transmitted Packets are getting dropped | Transmitted packets are getting dropped on the NSX-T Logical Switch and associated entities might get affected | No |
| 1.3.6.1.4.1.6876.100.1.0.80262 | NSXTRxPacketDropOnMPNicEvent | Warning | Received packets are dropping on NSX-T Management Node's network interface | Received packets are getting dropped on NSX-T Management Node's network interface. This may impact the network traffic related to NSX-T management cluster. | No |
| 1.3.6.1.4.1.6876.100.1.0.80263 | NSXTRxPacketDropOnEdgeTnNicEvent | Critical | Received packets are dropping on NSX-T Edge Node's network interface | Received packets are getting dropped on NSX-T Edge Node's network interface. This may impact the network traffic of edge cluster. | No |
| 1.3.6.1.4.1.6876.100.1.0.80264 | NSXTRxPacketDropOnHostTnNicEvent | Warning | Received packets are dropping on NSX-T Host Node's network interface | Received packets are getting dropped on NSX-T Host Node's network interface. This may impact the network traffic on ESX host. | No |

| OID | Event Name | Default Severity | UI Name | Description | Optimized for quick notification? |
|---|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80265 | NSXTTxPacketDropOnMPNicEvent | Warning | Transmitted packets are dropping on NSX-T Management Node's network interface | Transmitted packets are getting dropped on NSX-T Management Node's network interface. This may impact the network traffic related to NSX-T management cluster. | No |
| 1.3.6.1.4.1.6876.100.1.0.80266 | NSXTTxPacketDropOnEdgeTnNicEvent | Critical | Transmitted packets are dropping on NSX-T Edge Node's network interface | Transmitted packets are getting dropped on NSX-T Edge Node's network interface. This may impact the network traffic of edge cluster. | No |
| 1.3.6.1.4.1.6876.100.1.0.80267 | NSXTTxPacketDropOnHostTnNicEvent | Warning | Host Node's network interface | Transmitted packets are getting dropped on NSX-T Host Node's network interface. This may impact the network traffic on ESX host. | No |
| 1.3.6.1.4.1.6876.100.1.0.80402 | NSXTMPNodeServiceCmInventoryStatusEvent | Warning | CM Inventory Service has stopped running | CM Inventory Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80403 | NSXTMPNodeServiceControllerStatusEvent | Critical | Controller Service has stopped running. | Controller Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80404 | NSXTMPNodeServiceDataStoreStatusEvent | Critical | DataStore Service has stopped running. | DataStore Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80405 | NSXTMPNodeServiceHttpStatusEvent | Critical | HTTP Service has stopped running. | HTTP Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80406 | NSXTMPNodeServiceInstallUpgradeEvent | Critical | Install Upgrade Service has stopped running. | Install Upgrade Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80407 | NSXTMPNodeServiceLiagentStatusEvent | Critical | Liagent service has stopped running. | Liagent Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80408 | NSXTMPNodeServiceManagerStatusEvent | Critical | Manager Service has stopped running. | Manager Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80409 | NSXTMPNodeServiceMgmtPlaneBusStatusEvent | Critical | Management Plane Service has stopped running. | Management Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80410 | NSXTMPNodeServiceMigrationCoordinatorStatusEvent | Critical | Migration Co-ordinator Service has stopped running. | Migration Co-ordinator Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80411 | NSXTMPNodeServiceNodeMgmtStatusEvent | Critical | Node Management Service has stopped running. | Node Management Service status has turned to stopped. | Yes |

| OID | Event Name | Default Severity | UI Name | Description | Optimized for quick notification? |
|---|---|---|---|---|---|
| 1.3.6.1.4.1.6876.100.1.0.80412 | NSXTMPNodeServiceNodeStatsStatusEvent | Warning | Node Statistics Service has stopped running. | Node Statistics Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80413 | NSXTMPNodeServiceMessageBusStatusEvent | Warning | Message Bus Service has stopped running. | Message Bus Client Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80414 | NSXTMPNodeServicePlatformClientStatusEvent | Warning | Platform Client Service has stopped running. | Platform Client Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80415 | NSXTMPNodeServiceUpgradeAgentStatusEvent | Warning | Upgrade Agent Service has stopped running. | Upgrade Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80416 | NSXTMPNodeServiceNTPStatusEvent | Warning | NTP Service has stopped running. | NTP Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80417 | NSXTMPNodeServicePolicyStatusEvent | Warning | Policy Service has stopped running. | Policy Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80418 | NSXTMPNodeServiceSearchStatusEvent | Warning | Search Service has stopped running. | Search Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80419 | NSXTMPNodeServiceSNMPStatusEvent | Warning | SNMP Service has stopped running. | SNMP Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80420 | NSXTMPNodeServiceSSHStatusEvent | Warning | SSH Service has stopped running. | SSH Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80421 | NSXTMPNodeServiceSyslogStatusEvent | Warning | Syslog Service has stopped running. | Syslog Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80422 | NSXTMPNodeServiceTelemetryStatusEvent | Warning | Telemetry Service has stopped running. | Telemetry Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80423 | NSXTMPNodeServiceUIServiceStatusEvent | Warning | UI Service has stopped running. | UI Service status has turned to stopped. | Yes |
| 1.3.6.1.4.1.6876.100.1.0.80424 | NSXTMPNodeServiceClusterManagerStatusEvent | Critical | Cluster Manager Service has stopped | One of the Services of the NSX-T Management Node, namely Cluster Manager Service has stopped running. | Yes |

## NSX-T System Events

Here is the list of NSX-T 2.2 to 2.5 events supported in VCF Operations for networks. The Object ID (OID) for all these NSX-T system events is `1.3.6.1.4.1.6876.100.1.0.80203`.

Starting from 6.3 release, all NSX-T system events are optimized for quick notification and are delivered before 5 minutes.

**Table 1316: NSX-T System Events**

| Event Name | Description |
|---|---|
| vmwNSXPlatformSysCpuUsage | CPU Usage on both manager and edge appliances (NSX-T 2.2). |
| vmwNSXPlatformSysDiskUsage | Disk Space Usage on both manager and edge appliance for /var/log partition (NSX-T 2.2). |
| vmwNSXPlatformSysMemUsage | Memory Usage on both manager and edge appliance (NSX-T 2.2). |
| vmwNSXPlatformSysConfigDiskUsage | Disk Usage for Manager and Edge Appliances for /config partition (NSX-T 2.4). |
| vmwNSXPlatformSysVarDumpDiskUsage | Disk Usage for Manager and Edge Appliances for /var/dump partition (NSX-T 2.5). |
| vmwNSXPlatformSysRepositoryDiskUsage | Disk Usage for Manager and Edge Appliances for /repository partition (NSX-T 2.5). |
| vmwNSXPlatformSysRootDiskUsage | Disk usage for Manager and Edge appliances for root partition (NSX-T 2.5). |
| vmwNSXPlatformSysTmpDiskUsage | Disk usage for Manager and Edge appliances for tmp partition (NSX-T 2.5). |
| vmwNSXPlatformSysImageDiskUsage | Disk Usage for Manager and Edge appliances for /image partition (NSX-T 2.5). |
| vmwNSXDhcpPoolUsageOverloadedEvent | DHCP pool overloaded/normal (NSX-T 2.5). |
| vmwNSXDhcpPoolLeaseAllocationFailedEvent | DHCP pool lease allocation failed/succeeded (NSX-T 2.5). |
| vmwNSXPlatformPasswordExpiryStatus | Password expiration for manager (NSX-T 2.4). |
| vmwNSXPlatformCertificateExpiryStatus | Certificate expiration for manager (NSX-T 2.4). |
| vmwNSXRoutingBgpNeighborStatus | BGP neighbor status (NSX-T 2.2). |
| vmwNSXVpnTunnelState | VPN Tunnel up/down (NSX-T 2.2). |
| vmwNSXVpnL2TunnelStatus | L2 VPN Session up/down (NSX-T 2.2). |
| vmwNSXVpnIkeSessionStatus | IKE Session up/down (NSX-T 2.2). |
| vmwNSXDnsForwarderStatus | DNS Forwarder Status (NSX-T 2.4). |
| vmwNSXClusterNodeStatus | Cluster Node status (NSX-T 2.4). |
| vmwNSXFabricCryptoStatus | Edge crypto mux driver failed/passed Known_Answer_Tests(KAT) (NSX-T 2.4). |
| Manager Disk Utilization is not OK | |
| BGP Neighbor down | Need an alert when the BGP neighbor is down. |
| BGP Neighbor Up | Clear Alarm when a neighbor comes up. |
| Storage usage over X | Alarm for Storage over X - Event is raised for all appliance VM (MP, CCP) or transport nodes (edge, host). |
| Memory usage over X | Alarm for Memory over X - Event is raised for all appliance VM (MP, CCP) or transport nodes (edge, host). |
| CPU usage over X | Alarm for CPU over X - Event is raised for all appliance VM (MP, CCP) or transport nodes (edge, host). |

## NSX-T System Alarms

In addition to NSX-T events, all NSX-T 3.0 alarms are displayed as NSX-T system events in VCF Operations for networks 5.2 and later. You can see the complete list alarms generated by NSX-T at: *https://nsx-t_ip_address/nsx/#/app/home/alarms/alarm-definitions*. Here, replace *nsx-t_ip_address* with the IP address of your NSX-T instance.

> **Note:**
> Starting from 6.3 release, all NSX-T system alarms are optimized for quick notification and are delivered before 5 minutes.

## Kubernetes Events

Here is the list of Kubernetes alerts supported in VCF Operations for networks. The Object ID (OID) for all Kubernetes alerts is `1.3.6.1.4.1.6876.100.1.0.1510`.

| Event Name | Severity | Description |
|---|---|---|
| FailedToCreateContainer | Critical | Failed to create container |
| FailedToStartContainer | Critical | Failed to start container |
| PreemptContainer | Warning | Preempting other pods. |
| BackOffStartContainer | Warning | Back-off restarting failed the container. |
| ExceededGracePeriod | Warning | Container runtime did not stop the pod within specified grace period. |
| FailedToKillPod | Warning | Failed to stop a pod. |
| FailedToCreatePodContainer | Moderate | Failed to create a pod container. |
| FailedToMakePodDataDirectories | Moderate | Failed to make pod data directories. |
| NetworkNotReady | Warning<br>Critical | Network is not ready. |
| FailedScheduling | Critical | Unable to schedule pod |
| FailedToPullImage | Warning<br>Critical | Failed to pull the image. |
| FailedToInspectImage | Warning | Failed to inspect the image. |
| ErrImageNeverPullPolicy | Warning | The image's NeverPull Policy is violated. |
| ImagePullBackOff | Critical | Container image pull failed, kubelet is backing off image pull |
| ImageInspectError | Warning | Unable to inspect image |
| ErrImagePull | Critical | Image pull error |
| ErrImageNeverPull | Critical | Required Image is absent on host and PullPolicy is NeverPullImage |
| RegistryUnavailable | Critical | Getting http error when pulling image from registry |
| InvalidImageName | Critical | Unable to parse the image name |
| KubeletSetupFailed | Moderate | Kubelet setup failed. |
| FailedAttachVolume | Critical | Failed to attach volume. |
| FailedMountVolume | Critical | Failed to mount volume. |
| VolumeResizeFailed | Warning | Failed to expand/reduce volume. |
| FileSystemResizeFailed | Warning | Failed to expand/reduce file system. |
| FailedMapVolume | Critical | Failed to map a volume. |
| WarnAlreadyMountedVolume | Warning | Volume is already mounted. |
| ContainerGCFailed | Warning | Container garbage collection failed. |
| ImageGCFailed | Warning | Image garbage collection failed. |
| FailedNodeAllocatableEnforcement | Warning | Failed to enforce System Reserved Cgroup limit. |
| FailedCreatePodSandBox | Warning | Failed to create pod sandbox. |
| FailedStatusPodSandBox | Warning | Failed pod sandbox status. |
| InvalidDiskCapacity | Moderate | Invalid disk capacity. |
| FreeDiskSpaceFailed | Moderate | Free disk space failed. |
| ContainerUnhealthy | Critical | Container is unhealthy. |

| Event Name | Severity | Description |
|---|---|---|
| ContainerProbeWarning | Warning | Container Probe succeeded with a warning. |
| FailedSync | Warning | Pod sync failed. |
| FailedValidation | Warning | Failed pod configuration validation. |
| FailedPostStartHook | Warning | Handler failed for pod start. |
| FailedPreStopHook | Warning | Handler failed for pre-stop. |
| NodeNotReady | Critical | Node is not ready. |
| NodeNotSchedulable | Critical | Node is not schedulable. |
| NodeRebooted | Moderate | Node rebooted. |

## Configure Mail Server

In VCF Operations for networks, you can configure a mail server to receive alert notifications through mail.

To configure a mail server:

1. Go to **Settings** > **Alerts and Notification** > **Mail Server** > **CONFIGURE**.
2. In the **Configure Mail Server** page, enter appropriate values:

| Option | Action |
|---|---|
| Sender Email | Enter an email address where you want to get the notifications. |
| SMTP Hostname/IP Address | Enter a Hostname or IP address of the SMTP server. |
| Encryption | From the drop-down menu, select an encryption type.<br>The following encryption options are available: None, Use SSL, and Support TLS. |
| SMTP Port Number (Optional) | Port number of the SMTP server (default 25). |

**Note:**
To use a Gmail server as the choice of email server, additional configuration settings as listed on Google Support are required.

Optionally, for additional security, select the Authentication check box, and enter the user name and password.

3. Click **SUBMIT** to complete the configuration.

## Configure SNMP Trap Destination

In VCF Operations for networks, you can configure maximum four Simple Network Management Protocol (SNMP) trap agents to receive notifications. The product supports the v2c and v3 versions of SNMP:

1. Go to **Settings** > **Alerts and Notification** > **SNMP Trap Destinations** > **ADD DESTINATION**.
2. In the **Add SNMP Trap Destination** page, in the **Version** drop-down box, select **SNMPv2c** or **SNMPv3** protocol.

   **Note:**
   SNMP v2c protocol does not require authentication. SNMP v3 protocol supports authentication.
3. In the **Destination IP Address/FQDN** text box, enter the IP address of the SNMP agent or the Fully Qualified Domain Name (FQDN).
4. In the **Destination Port** text box, enter a port number of the SNMP agent.

5. Depending on the SNMP version, perform one of the following:

| Option | Action |
|---|---|
| For SNMP v2c | In the **Community String** text box, enter a community string. |
| For SNMP v3 | 1. In the **Username** text box, enter the name of the user you have created in the SNMP agent.<br>2. Select the **Use Authentication** check box.<br>3. Select an authentication protocol, and then enter the password you had set for the particular user in the SNMP agent.<br>4. Select the **Use Privacy**check box, and select a privacy protocol and enter a privacy phrase respectively. |

6. In the **Nickname** field, enter a nick name.
7. To verify whether the configuration is correctly done, click **SEND TEST TRAP**, and then check whether the trap has been sent to the SNMP agent.
8. Click **SUBMIT**.

#### Delete an SNMP Trap Destination

You can delete an SNMP Trap Destination from VCF Operations for networks. If you have multiple SNMP Trap Destinations, then when you delete an SNMP Trap Destination, you can migrate all the notification related to that trap destination to another available trap destination.

1. Click the **Delete** icon next to the trap destination you want to delete.

   A **Confirm Action** pop-up opens.
2. If you want to migrate the alert from the current trap destination to another trap destination, click **Select multiple destinations** drop-down and select the trap destination where you want to migrate the alerts.
3. Click **CONFIRM**.

## Configuring Identity and Access Management

In VCF Operations for networks, you can create users, or configure the access of LDAP users and VMware Identity Manager users. You can also assign different roles to the users.

### User Roles

VCF Operations for networks supports three types of user roles for a user. Users can access VCF Operations for networks features based on the assigned roles.

- **Admin:** An administrator has complete access.
- **Member:** A member user has limited access.
- **Auditor:** An auditor has read-only access, and restricted from all create, add, edit, or delete actions. Users can only view the state.

**Table 1317: Supported features for each role**

**Add Local Users**

VCF Operations for networks allows you to add users and assign a role to each user.

1. Go to **Settings** > **Identity & Access Management** > **User Management** .
2. On the User Management page, select the **Local Users** tab.
3. Click **ADD USER** and provide the required details.

| Properties | Description |
|---|---|
| Name | Enter the name of the user. |
| Email (Login ID) | Enter your email or login ID if any. |
| Role | Select the role from drop-down list. |
| Password | Enter the password. |
| Re-enter new password | Re-enter the password for confirmation. |

4. Click **Add User** to save the user information.

**Assign Roles to LDAP Users**

You can assign roles to any LDAP users to allow access to VCF Operations for networks.

Configure LDAP.

1. Go to **Settings** > **Identity & Access Management**.
2. Click **User Management** and select the **LDAP Users** tab.
3. Click **ADD USER**.
4. Provide the login ID of the user to whom you want to assign a role.
5. Select a role from the list. For details, see Configure User Management.
6. Click **ADD USER**.

Configure Lightweight Directory Access Protocol (LDAP)

To allow the LDAP users to log into VCF Operations for networks, you must configure the LDAP service in the VCF Operations for networks platform.

You must have the **Administrator** privilege.

**Note:**
VCF Operations for networks supports the LDAP and LDAPS protocols.

1. Log in to VCF Operations for networks and click **Settings**.
2. Under **Identity & Access Management**, select **LDAP**.
3. Click **Configure**.
4. Provide the following information.

| Field | Description |
|---|---|
| **Domain** | Enter the domain name. This is typically the last part of the user email address after the '@' sign. Example: For a user logging in as johndoe@example.com, this field is `example.com` |
| **LDAP Host URLs** | Enter the host name. You can specify multiple LDAP Host URLs separated by commas. The URLs can be of type IPv4, IPv6, or FQDN.<br>Examples:<br>• IPv4: (ldap://192.168.1.1:389)<br>• IPv6: (ldap://[fc00:192:168:20::e]:389)<br>• FQDN: (ldap://host:port/ldaps://host:port) |
| **Group based access control** | Select this option to configure a group and provide a role to the members of that group.<br>1. Under**Base DN**, type the Base DN, the point from which the server starts searching for users.<br>2. Provide the search attribute.<br>3. Under **Group DN**, select the role of the user for each group. If you select the administrator role for a particular group, then all the members of that group have the administrator privilege. Similarly, if you select the member role for a particular group, then all the members of that group have the member privilege. If this option is not selected, then the group setting is used to assign the privileges. But other valid LDAP users who do not belong to the groups that you have added can log in to the product.<br>4. Click **Add more** to add groups in the inclusion list.<br>5. Select the **Restrict access to members of the above groups only** option to allow access to the users only from the LDAP groups (direct or inherited membership) that you have added. |
| **Username** | User with the necessary rights to log in using the settings provided. |
| **Password** | Password of the user. |

5. Click **SUBMIT**.
   After configuration, you see the **LDAP** details you have configured.

**Import Users from VMware Identity Manager**
You can import VMware Identity Manager user accounts to allow them to use VCF Operations for networks and assign them the roles.

Configure VMware Identity Manager.

**Note:**
If you are switching your authentication method to VMware Identity Manager from LDAP and the domain used in VMware Identity Manager is the same as the LDAP authentication source, you must delete all LDAP users and settings before you switch to VMware Identity Manager.

1. Go to **Settings** > **Identity & Access Management**.
2. Click **User Management** and select the **VMware Identity Manager Users** tab.
3. Click **ADD USER** and provide the required details.

| Field Name | Description |
|---|---|
| Domain Name | Enter the VMware Identity Manager domain name for import. |
| Search Users/Groups | Enter a search string, and select the user account from the autocomplete list. You can either select a single user or select a user group. If you select a group, all the members in the group can access to VCF Operations for networks. |
| Role | Assign a role to the user account. For more information, see Configure User Management. |

4. Click **Add User**.

**Note:**

- If you have selected a group, all the members in the group are assigned the same role. If you want to assign a different role to a specific user in the group, you must add the user individually, and assign the required role. For example, to assign the **Administrator** role only to *user1* in *Mygroup*, perform the following steps:
  1. Add *Mygroup* and assign the **Member** role.
  2. Add *user1* and assign the **Administrator** role.

  The role assigned to the user overwrites the role assigned to the user as a part of group.
- If a user belongs to multiple groups with different roles, the highest privilege role is assigned to the user. For example, if a user belongs to *Group A* that has the **Administrator** role, and also belongs to *Group B* and *Group C* that have the **Member** role, the user inherits the **Administrator** role.

The VMware Identity Manager users or group members can log in to VCF Operations for networks and use the features based on the assigned role.

Configure VMware Identity Manager

Administrators can authorize VMware Identity Manager users for accessing VCF Operations for networks features based on their roles.

Register VCF Operations for networks as an OAuth client to the VMware Identity Manager host. For more information see the VMware Workspace ONE Access Documentation.

1. Log in to VCF Operations for networks and click **Settings**.
2. Under **Identity & Access Management**, select **VMware Identity Manager**.
3. Click **Configure**.
4. Provide the following information.

| Parameter | Description |
|---|---|
| VMware Identity Manager Appliance | The fully qualified domain name (FQDN) of the VMware Identity Manager host. |
| OAuth Client ID | The ID that is created when registering VCF Operations for networks to the VMware Identity Manager host. |
| OAuth Client Secret | The secret that is created when registering VCF Operations for networks to the VMware Identity Manager host. |

| Parameter | Description |
|---|---|
| SHA-256 Thumbprint | This is an optional field. The certificate thumbprint of the VMware Identity Manager host. For more information, see Obtain the Certificate Thumbprint from a vIDM Host. |

5. Click **Submit**.

   After configuration, you see the VMware Identity Manager appliance and the client details you have configured.

6. Click the toggle button to enable or deactivate VMware Identity Manager. If you deactivate, you cannot use the VMware Identity Manager authentication in VCF Operations for networks.

Obtain the Certificate Thumbprint from the VMware Identity Manager Host

For the SSL certificate validation, you can obtain the SHA-256 thumbprint from VMware Identity Manager host.

1. To get the SSL/TLS certificate, run the following command:

   ```
   openssl s_client -connect <FQDN of vIDM host>:443
   ```

   Copy the Server Certificate starting from `-----BEGIN CERTIFICATE-----` to `-----END CERTIFICATE-----` into a file called `cert.pem` and save the file.

2. To get the thumbprint, run the following command:

   ```
   openssl x509 -fingerprint -noout -sha256 -in cert.pem
   ```

You see the thumbprint in the following format:

```
SHA256
Fingerprint=3D:E8:4C:CD:19:D6:AD:23:30:86:E4:A1:72:D5:22:08:F9:72:6D:D3:E7:6E:99:32:C8:C7:3D:F8:
```

Copy the thumbprint and paste it in the configure VMware Identity Manager page.

## Configuring Logs

In VCF Operations for networks, you can view and configure different types of logs.

### View and Export Audit Logs

Audit logs capture administrative actions carried out in the system. These actions are regular CRUD operations, and login/logout alerts. The audit logs capture the actions from the API, the user interface, and the CLI.

- The audit log feature is always on.
- VCF Operations for networks supports the UTC format in the audit logs.
- The audit log is integrated with the syslog. You can configure the syslog collector to collect all the audit logs.
- You can export all the audit log data in a CSV file.

Currently, the following administrative actions are not captured in audit logs:

- SSH login logs. You can find the SSH logs in `/var/log/auth.log`.
- Changes in Physical IP and DNS Mapping.
- Changes in Physical Subnets and VLANS.

1. Go to **Settings** > **Logs** > **Audit Logs**.
2. The following details are shown on the **Audit Logs** page:

| Information | Description |
|---|---|
| `Date & Time` | Timestamp of the actual action performed. |
| `IP Address` | IP address of the client from which the connection is established such as the CLI or the browser. |
| `User Name` | User who is performing the action. |

| Information | Description |
|---|---|
| Object Type | Object on which the action is being performed. |
| Operation | Different actions that the user performs on the object. |
| Object Identifier | Unique identifier for that particular object on which the action is being performed. |
| Response | Indicator for success or failure of the operation |
| Details | Details of the settings that have been changed such as the nickname or a property. |

3. To allow the collection of information when the user logs in through a browser or CLI, enable **Allow collection of Personally Identifiable Information**. This option is deactivated by default.

   **Note:**
   The IP Address and the User Name columns are blank if this option is deactivated.

4. Click **Export as CSV** to export the audit log data in the CSV format.

### Setup Syslog Configuration

You can configure remote syslog servers for VCF Operations for networks by using the **Syslog Configuration** page.

While every collector can potentially have a different remote syslog server, all the platform servers in a cluster use the same remote syslog server.

In the current release, the VCF Operations for networks problem alerts and platform or collector syslogs are sent to the remote syslog server.

Currently, VCF Operations for networks supports only UDP for communication between VCF Operations for networks servers and remote syslog servers. So ensure that your remote syslog servers are configured to accept syslog traffic over UDP.

To configure syslogs:

1. In the **Settings** page, under **Logs**, click **Syslog Configuration**.
   The **Syslog Configuration** page has the configured syslog servers and their mappings to the virtual appliances listed. If you are accessing this page the first time, then the syslog is deactivated by default and the list of servers on this page does not appear.
2. To add a syslog server:
   a. Click **Add Server**.
   b. Enter the IP Address, nickname, and port number of the server. The standard port number for UDP is 514.
      The IP address can be an IPv4 address, IPv6 address, or a fully qualified domain name.
   c. To test the configuration, click **Send Test Log**.
   d. Click **Submit**.
   e. If it is the first server that you have added, then enable syslog at the top of the page.
3. To map the server to platforms, alerts, or collectors:
   a. Under **Source - Server Mapping**, individually edit the server for all platforms, alerts, or collectors.
   b. Select the syslog server.
   c. If you do not want to enable syslog, select the **No server** option.
   d. Click **Submit**.

   **Note:**
   After you make the changes, it can take a few minutes for them to be effective.

## Configuring Web Proxies

In VCF Operations for networks, you can configure web proxies to connect to other entities (data sources, cloud service platforms, and so on) when the connection is made over the Internet.

You can add, edit, and delete web proxies in VCF Operations for networks.

**Note:**
This feature is supported for the following data sources:

| Data Sources | Web Proxy (HTTP) | Web Proxy (HTTPS) |
|---|---|---|
| Service Now | Yes | Yes |
| Amazon Web Services | Yes | Yes |
| Microsoft Azure | Yes | No |
| VMware Cloud on AWS - NSX Manager | Yes | Yes |

**Note:**
To enable a web proxy, you must edit the data source and select a web proxy from the **Web Proxy (Optional)** drop-down menu.

## Supported Web Proxies

In VCF Operations for networks, you can add the following types of web proxies:

- HTTP and HTTPS unauthenticated web proxy
- HTTP and HTTPS authenticated web proxy with the basic authentication
- HTTP web proxy with the NTLM authentication supported through CLI only.

**Note:**
If you set NTLM authentication-based web proxy using CLI on a platform VM, then the platform VM cannot communicate with Cloud Service Providers (CSP). This is because currently, we do not support communication with CSP using NTLM web proxy.

## Add a Web Proxy

1. Go to **Settings** > **Web Proxies** > **ADD WEB PROXY**.
2. In the **Add Web Proxy** window, do the following:

| Option | Action |
|---|---|
| Type | Select a web proxy type from the drop-down menu. |
| IP Address/FQDN | Enter the IP/FQDN of the web proxy you want to add. |
| Port | Enter the port number used by the web proxy. |
| Nickname | Enter a nick name for the web proxy. |

3. Select the **Use credentials** check box, and provide a username, password, and authentication method.
4. Click **SUBMIT**.

## Edit and Delete a Web Proxy

To Edit a web proxy, do the following:

1. **Settings** > **Web Proxies**.
2. In the **Web Proxies** page, click the edit icon next to the web proxy you want to edit, and modify the information as required.
3. Click **SUBMIT**.

**Note:**
You cannot edit web proxies added using CLI.

To delete a web proxy, do the following:

1. Click the delete icon next to the web proxy you want to delete.

**Note:**
Make sure that the web proxy you want to delete has zero **Connected Entities**. If you have one or more **Connected Entities**, then you must migrate the entities to a different web proxy before moving to the next step.

2. In the **Confirm Action** window, click **DELETE**.

**Collector Migration for Web Proxies**

Before migrating collector to version 6.1, if you set a web proxy on the collector using CLI, and if you set the flag `isHttpProxyEnabled = TRUE`, then all the data sources which were reachable through the web proxy, work seamlessly after the migration to 6.1 as the system auto applies the web proxy details to these data source configurations.

**Note:**
During Collector migration to version 6.1, if you set a web proxy on the collector using CLI, and if you set the flag `isHttpProxyEnabled = FALSE` then Amazon Web Services and Microsoft Azure data sources may not work after migration. You have to select a web proxy for both Amazon Web Services and Microsoft Azure data sources from the **Accounts and Data Sources** page. See Supported Public Cloud Accounts for details.

## VCF Operations for networks License

The capabilities of VCF Operations for networks are dependent on the license applied to your vCenter instance.

Starting with version 9, product components, including VCF Operations for networks, are licensed automatically after you license the vCenter instance connected to the component. You no longer license VCF Operations for networks, manually. For more information, see Licensing Overview.

**Note:**

After upgrading to VMware vSphere 9, the vSphere deployment will be in evaluation mode. As a result, the deployment becomes unsupported in VCF Operations for networks, and data collection is paused. After adding a valid license to your vSphere deployment becomes supported again but data collection must be turned back on manually.

## Configure Auto-Refresh Interval

In VCF Operations for networks, you can configure auto-refresh interval for entity pages and dashboards.

VCF Operations for networks provides the auto-refresh feature for the entity dashboards and dashboards. The dashboard refreshes automatically once in every *n* minutes specified on the header bar.

You can specify the time interval for which you want all your dashboards to perform an auto refresh. After the specified time interval (*n* minutes), all the open widgets on the dashboard will reload automatically.

**Note:**

- You cannot change the auto-refresh time interval for a particular dashboard.
- Auto-refresh is paused if you select a past time interval in timeline slider.

You can pause auto-refresh if you do not require it for a particular dashboard. On the header bar, set **Pause** to **ON**. The auto-refresh counter resets once you set **Pause** to **OFF**.

If you are viewing a dashboard and if another user is making changes to it such as changing the layout of the dashboard, the auto-refresh feature not only updates the content but also refreshes the entire dashboard. This occurs only if sharing and collaboration exists between you and the other user.

1. On the **Settings** page, click **My Preferences**. Or on the respective dashboard, click **Modify** next to Auto-Refresh in the header bar.
2. Click **Edit** to change the time interval for auto-refresh. Select the time interval from the drop-down menu. Click **Save**.
3. To deactivate the auto-refresh option, select **Disabled** from the drop-down menu. All the dashboards are deactivated from refreshing automatically if you select this option.

## Enabling Support for IPv6 Flow Processing

VCF Operations for networks collects and processes IPv6 flows from VMware vCenter and NSX data sources.

IPv6 is designated by the Internet Engineering Task Force (IETF) as the successor to IPv4 providing the following benefits:

- Increased address length. The increased address space resolves the problem of address exhaustion and eliminates the need for network address translation. IPv6 uses 128-bit addresses compared with the 32-bit addresses used by IPv4.
- Ability for improved address autoconfiguration of nodes.

1. On the **Settings** page, click **System Configuration**.

   **Note:**
   The **System Configuration** tab is visible only to the `admin user`.

2. Switch the **IPv6 Flow Processing** toggle to true.

   **Note:**

   As IPv6 addresses occupy more space in memory and disk, enabling IPv6 flow processing can reduce the platform and the collector capacity by up to 20%.

After you enable this feature, VCF Operations for networks takes a few minutes to start collecting and processing IPv6 flows.

To view the list of IPv6 flows, from the left navigation, go to **Entities** > **Flows** and filter flows by **Flow Type**.

## Configure User Session Timeout

By default, the user session timeout is set to `15` minutes. You can modify this value according to your preference.

1. On the **Settings** page, click **System Configuration**.

   **Note:**
   The **System Configuration** tab is visible only to the `admin user`.

2. To change your preference for the **User Session Timeout**, click **EDIT**.
3. Drag the slider bar to set the timeout value for the session. The value ranges from `15` minutes to `24` hours.
4. You can also view the details on who modified the timeout value and when in the **Last Modified** field.
5. Click **Submit**. The Success message appears to confirm that the updated session duration will be effective from the next login.

   **Note:**
   The new value for the user session timeout will come into effect only after you log out and log in again.

## Add Google Maps API Key

To get the map view of your SD-WAN deployment, you must add a Google Maps API key in VCF Operations for networks.

Ensure the following:

- You are a member of Google Cloud Platform and billing is enabled in your account.
- You have the Google map API access key for the following API:
  - Maps JavaScript API
  - Geocoding API

  To get the API key, see Get an API key procedure in *Google Maps Platform documentation*.
- You have restricted the API key to prevent any misuse. To know more, see Restrict the API key in *Google Maps Platform documentation*.

1. On the **Settings** page, click **System Configuration**.
2. In the **Google Maps API Key**, enter the API key and click **Save**.

## VCF Operations for networks and FIPS

In VCF Operations for networks enforces FIPS 140-2 validated cryptographic modules for all internal and external connections. FIPS mode is always enabled and cannot be disabled.

FIPS 140-2 is a U.S. and Canadian government standard that specifies security requirements for cryptographic modules. VCF Operations for networks uses FIPS 140-2 validated cryptographic modules for all internal and external connections. The objective of introducing FIPS support in VCF Operations for networks is to simplify compliance with security requirements in regulated environments..

> **Note:**
>
> Starting with version 9.1, new instances of VCF Operations for networks use FIPS-approved cryptographic modules by default. No additional configuration is required to enable FIPS compliance. Upon upgrading, all appliances that were not previously fully FIPS compliant are automatically brought into compliance.

VCF Operations for networks uses the following validated modules:

| FIPS Object Module | Version | Certificate |
|---|---|---|
| VMware's OpenSSL | 3.0.8 | Certificate #4013 |
| BC-FJA (Bouncy Castle FIPS Java API) | version 2.0.0 | Certificate #37009 |

You can find more information about the cryptographic modules that VMware has validated against the FIPS 140-2 standard from here: https://www.vmware.com/security/certifications/fips.html.

## Configure Security Certificate Validation

When you add a data source, or configure LDAP and VMware Identity Manager (vIDM) in VCF Operations for networks, all the certificates related to that data source, LDAP, or vIDM are validated. In VCF Operations for networks, you can configure how you want to validate and accept the certificates.

There are two ways you can configure certificate validation: **Automatic Acceptance** and **Manual Acceptance**. In **Automatic Acceptance**, system automatically accepts all the detected certificate changes, and in **Manual Acceptance**, system show you notification to accept the certificate manually.

1. Go to **Settings** > **System Configurations**.
2. From **Security Certificate Validation** drop-down menu, select one of the validation methods:
   - **Automatic Acceptance**
   - **Manual Acceptance**
3. Click **Save**.

> **Note:**
>
> If you change the certificate validation method from **Manual Acceptance** to **Automatic Acceptance**, you must accept all the available certificate changes manually before you change the certificate validation method.
>
> If you change the **Data Source Certificate Validation** from **Manual Acceptance** to **Automatic Acceptance** without accepting the pending detected certificate changes, then you have to delete all the data source with pending certificate and add them again to get the insight about those data sources.
>
> The security certification validation setting is not applicable to the following data sources: vCenter, NSX-T, and VCF Operations for logs .
>
> Certificate acceptance for these data sources is handled automatically. If automatic acceptance fails, users must manually accept the certificate by navigating to the **Accounts and Data Sources** page.

For IPV6-enabled vCenter, NSX-T, and VCF Operations for logs data sources, automatic certificate acceptance is not supported. In these cases, users must manually accept the certificate by navigating to **Settings** > **Accounts and Data Sources**.

When the certificate of a non-VIP node in an NSX-T cluster is updated using the VCF Operations Console, users are required to manually accept the new certificate through the same path.

### Accept a Data Source Certificate Manually

If you have configured **Security Certificate Validation** as **Manual Acceptance**, then you must accept the new certificate (HTTPS certificate or SSH public key) for each data source whenever the system detects any change in certificate.

When you add a data source in VCF Operations for networks, all the certificates (HTTPs certificates or SSH public keys) related to that data source are automatically added as a trust on first use. After you add the data source in VCF Operations for networks, every time there is any change in the certificate, the system validates the certificate.

If you have configured **Data Source Certificate Validation** as **Manual Acceptance**, whenever VCF Operations for networks detects any changes in the certificate, it stops the data source and shows you an alert message notification to accept the certificate manually. When you accept the certificate, the system starts the data source. You can also see the certificate change alert in the **Accounts and Data Sources** page. Use this procedure to accept the certificate.

In the **Data source certificate update available** alert message notification, click **REVIEW**.

| | |
|---|---|
| **If the number of certificates update available is up to two:** | 1. You see a **Data Source Certificate** window with current certificate and new certificate details.<br>2. Review the new certificate and click **ACCEPT**. |
| **If the number of certificates update available is more than two:** | 1. In the **Accounts and Data Source** page, you see the `Certificate update available. Click here to review and accept` message under the data source where the certificate update is available.<br>2. Click **Click here to review and accept** for the data source you want to review and accept the updated certificate.<br>3. You see a **Data Source Certificate** window with the current certificate and new certificate details.<br>4. Review the new certificate and click **ACCEPT**. |

When you accept the new certificate, you see `Successfully updated the certificate` message.

### Accept vIDM and LDAP Certificate Manually

If you have configured **Security Certificate Validation** as **Manual Acceptance**, then you need to accept the new certificate (TLS/SSL X.509) to configure the vIDM or LDAP successfully.

When you configure the vIDM or LDAP in VCF Operations for networks, and configure the **Security Certificate Validation** as **Manual Acceptance**, you see an alert message notification to accept the certificate. You also see the alert message notification whenever the system detects any changes in the security certificates.

**Note:**
Only an **Admin user** can accept a security certificate. If you do not accept the certificate, the vIDM or LDAP users cannot access VCF Operations for networks.

You can review and accept the security certificate when you see the security alert message notification. To accept the certificate, do the following:

- For vIDM, when you see the **VMware Identity Manager security certificate update** alert message notification, click **ACCEPT**.
- For LDAPS, when you see the **LDAP Security certificate update** alert message notification, click **ACCEPT**.
- For LDAPS, If the number of certificates update available is more than two, you see `Certificate update available since <date>. Click here to review and accept` in the LDAP tab.
  a. Click **Click here to review and accept** for the LDAPS server you want to review and accept the updated certificate.

b. Review the certificate, and click **ACCEPT**.

## Join or Leave the Customer Experience Improvement Program

VCF Operations for networks participates in VMware's Customer Experience Improvement Program (CEIP). This program provides with information that enables VMware to improve its products and services, correct problems, and advise you on how best to deploy and use the products.

As part of the CEIP, VMware collects the technical information about your organization's use of the VMware products and services regularly using your organization's VMware license keys. This information does not personally identify any individual.

Details regarding the data collected through CEIP and the purposes for which it is used by VMware are set forth in the Trust & Assurance Center at VMware Products in CEIP Program.

You can join or leave the Customer Experience Improvement Program (CEIP) for VCF Operations for networks.

1. Navigate to **Settings** > **Infrastructure and Support** > **Support**.
2. Click **Edit** next to **Customer Experience Improvement Program**.
   The **Customer Experience Improvement Program** window opens.
3. To join CEIP, click the **Join the VMware Customer Experience Improvement Program** check box.
   This action activates CEIP and sends data to https://vmware.com.
4. To leave CEIP, deselect the **Join the VMware Customer Experience Improvement Program** check box.
5. Click **Submit**.

## Configure Login Banners

You can configure Login Banners in VCF Operations for networks to display any text, or you can require that the user click a check box, for example, to indicate that they accept terms and conditions. You can enable and deactivate the login banners, and you can require that users click an explicit consent check box.

1. On the Settings page, click **System Configuration**.
2. Click **Edit** in the **Login Banners** row and configure the login banners.

| Option | Description |
|---|---|
| Display Banners | Click the toggle button to enable or deactivate login banners. You can change the other fields only if you enable this option. |
| Login Message Banner | In the **Description** box, enter the message that you want the users to see when they login to VCF Operations for networks. |
| User Consent Form | Enter the title and enter the content message you want to display. This requires that the users agree to the consent before logging in to VCF Operations for networks. |

3. Click **Submit**.
   The login banners are configured and displayed when a user logs in to VCF Operations for networks.

## CLI Commands

The following section includes various useful Command Line Interface (CLI) commands you can use to configure VCF Operations for networks. To use the CLI commands, log in to the VCF Operations for networks appliance as a *consoleuser*.

The following is a table including useful keyboard shortcuts you can use when applying CLI commands:

| Keyboard Shortcut | Function | Example |
|---|---|---|
| `ctrl+u` | To undo a complete line (to provide the same effect as `ctrl+c` which has some other specific interpretation in CLI) | `(cli) modify-password system --user foo`<br>Using `ctrl+w` in the preceding example results in:<br>`(cli)` |
| `ctrl+w` | To undo words | `(cli) modify-password system --user foo`<br>Using `ctrl+u` in the preceding example results in:<br>`(cli)modify-password system --user` |

### `appliance-reboot`

This reference includes examples for syntax information for the `appliance-reboot` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `appliance-reboot` | Reboots the appliance | `appliance-reboot [-h] {now}` | `appliance-reboot now` |

Syntax

| Flag | Description |
|---|---|
| `positional arguments: {now}` | Used to avoid the accidental invocation. |

## backup-restore

This reference includes examples for the `backup-restore` command.

For more information about backup and restore and how to run the process, see About Backing up and Restoring of Deployment Data.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `backup-restore` | • Configures backup<br>• Updates Configured backup<br>• Fetches existing backup configuration<br>• Deletes existing backup configuration<br>• Displays backup Status<br>• Displays usage details of the `backup` command | backup-restore backup --action {add\|update\|get\|delete\|status\|help} | • `backup-restore backup --action add --pathconfig-file-path`<br>• `backup-restore backup --action update --pathconfig-file-path`<br>• `backup-restore backup --action get`<br>• `backup-restore backup --action delete`<br>• `backup-restore backup --action status`<br>• `backup-restore backup --action help` |
| `backup-restore` | • Configures restore<br>• Fetches existing restore configuration<br>• Deletes existing restore configuration<br>• Displays restore Status<br>• Displays usage details of the `restore` command | backup-restore restore --action {add\|get\|delete\|status\|help} | • `backup-restore restore --action add --pathconfig-file-path`<br>• `backup-restore restore --action get`<br>• `backup-restore restore --action delete`<br>• `backup-restore restore --action status`<br>• `backup-restore restore --action help` |

### `change-network-settings`

| Command | Description | Usage | Examples |
|---|---|---|---|
| `change-network-settings` | Change network configuration of the appliance. You must use the VM console through the vCenter UI to perform this operation.<br>**Note:**<br>The appliance is rebooted in the end. | `change-network-settings` | `change-network-settings` |

Syntax

| Flag | Description |
|---|---|
| `none` | NA |

**disk-usage**

This reference includes examples for syntax information for the `disk-usage` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `disk-usage` | Displays current disk partition disk usage statistics. | `disk-usage` | `disk-usage` |

## finalize-IP-change

This reference includes information for the `finalize-IP-change` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `finalize-IP-change` | Execute the final set of configuration changes after IP change. You must run this command on one of the platforms after completing the IP change workflow (`update-IP-change`) | `finalize-IP-change` | `finalize-IP-change` |

**help**

This reference includes examples for syntax information for the `help` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `help` | Displays a list of commands with a short description about their use. | To view the list of commands without short description, use the `-a` flag. | `help`<br>`help -a` |

## hostname

This reference includes examples for the `hostname` command.

| Command | Description | Usage | Example |
|---|---|---|---|
| `hostname show` | Shows the current host name of the VCF Operations for networks | `hostname show` | `hostname show` |
| host name update | Updates the host name of VCF Operations for networks collector or platform VMs. | `host name update` | `host name update --help hostname update --hosts <new_hostname>`<br>`hostname update --hosts platform1:<new_hostname1> platform2:<new_hostname2> platform3:<new_hostname3>` |

**Table 1318: Syntax**

| Flag | Description |
|---|---|
| --dryrun | Validates the new hostname without updating the hostname in VCF Operations for networks.<br>Example:<br>`hostname update --dryrun --hosts <new_hostname>`<br>`hostname update --dryrun --`<br>`hosts platform1:<new_hostname1>`<br>`platform2:<new_hostname2>`<br>`platform3:<new_hostname3>` |
| --hosts | Updates the hostname of your VMs in VCF Operations for networks..<br>Example:<br>`hostname update --hosts <new_hostname>`<br>`hostname update --hosts platform1:<new_hostname1>`<br>`platform2:<new_hostname2>`<br>`platform3:<new_hostname3>` |
| --help | Shows all the supported options.<br>Example:<br>`hostname update --help` |

## aria-logs

This reference includes examples for the syntax information for the `aria-logs` command.

**Table 1319: Command**

| Command | Description |
|---|---|
| `aria-logs` | Configures and pushes various logs to the VCF Operations for logsserver. |

### Syntax

The `aria-logs` command supports the `show` flag. This flag displays the currently configured VCF Operations for logs agent and its status.

## logout

This reference includes examples for syntax information for the `logout` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `logout` | Exits from the interactive shell of the CLI. | | |

### log-trace

This reference includes examples for syntax information for the `log-trace` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `log-trace` | Displays a list of all log files and also component-specific logs that help during debugging. | `log-trace [-h] {list,grep,follow,display}` | `log-trace list`<br>`log-trace follow /var/log/arkin/arkin_cli_install.log`<br>`log-trace grep "ERROR" /var/log/arkin/arkin_cli_install.log`<br>`log-trace display /var/log/arkin/arkin_cli_install.log 20 (to display last 20 lines)` |

Syntax

| Flag | Description |
|---|---|
| `list` | Lists all log files that can be displayed and also lists the component-specific logs.<br>Example:<br>`log-trace list` |
| `follow` | Usage:<br>`log-trace [-h] follow <file name>`<br>Example:<br>`log-trace follow /var/log/arkin/arkin_cli_install.log` |
| `grep` | Usage:<br>`usage: log-trace grep [-h] pattern filename`<br>Example:<br>`log-trace grep "ERROR" /var/log/arkin/arkin_cli_install.log` |
| `display` | Usage:<br>`usage: log-trace display [-h] filename numlines`<br>Example:<br>`log-trace display /var/log/arkin/arkin_cli_install.log 20 (to display last 20 lines)` |

### modify-password

You can use the `modify-password` command to reset the password of the UI or the system user.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `modify-password` | Reset the password of the UI or the system user<br>`(cli) modify-password [-h]` | `modify-password [-h] {system, ui}` | `modify-password system`<br>`modify-password ui` |

**Table 1320: Syntax**

| Flag | Description |
|---|---|
| `positional arguments: {system, ui}`<br><br>`optional arguments: -h, --help` | Example invocations:<br>`modify-password ui [-h] --user USER`<br>`modify-password system [-h] --user {support,consoleuser}` |

### nslookup

This reference includes examples for syntax information for the `nslookup` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `nslookup` | Queries the Internet name servers interactively. | `nslookup FQDN` | `nslookup example.com` |

Syntax

| Flag | Description |
|---|---|
| `fqdn` | Server name to query such as `example.com`. |

Related Commands

| Command | Description |
|---|---|
| `ping` | Pings a machine. |
| `telnet` | Tests whether a specific TCP port is open. |
| `traceroute` | Prints route IP packets sent to a remote host. |

### ntp

This reference includes examples for syntax information for the `ntp` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `ntp show` | To show the current configuration and status | | |
| `ntp sync` | To force the sync | | |
| `ntp set` | To reset the servers | `ntp set [--ip-fqdn] [--secure]` | `ntp set --ip-fqdn "a.b.me,x.y.z.local"`<br>`ntp set --ip-fqdn "a.b.me,x.y.z.local" --secure` |
| `ntp diagnose` | To print debug data | | |

**Syntax**

Positional arguments for the `ntp set` command:

| Flag | Description |
|---|---|
| `ip-fqdn` | IP addresses or FQDN details of the NTP servers. |
| `secure` | (Optional) If the IP addresses or FQDN details are of secure NTP servers. |

### `ping`

This reference includes examples for syntax information for the `ping` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `ping` | Pings a host. | `ping host` | `ping example.com` |

Syntax

| Flag | Description |
|---|---|
| `host` | IP address or FQDN of the host to ping. |

Related Commands

| Command | Description |
|---|---|
| `nslookup` | Queries Internet name servers interactively. |
| `telnet` | Tests whether a specific TCP port is open. |
| `traceroute` | Prints route IP packets sent to a remote host. |

### `telnet`

This reference includes examples for the syntax information for the `telnet` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `telnet` | Test whether a specific TCP port is open. This command is for the interactive communication with the host on a particular port number.<br>`PORT` is an optional parameter. You must provide a host other than `localhost` or 127.0.0.1. | `telnet host port` | `telnet 192.168.0.59 80`<br>`telnet example.com 80` |

Syntax

| Flag | Description |
|---|---|
| `host` | IP address or FQDN of the host to ping. |
| `port` | Port number of the host. |

Related Commands

| Command | Description |
|---|---|
| `nslookup` | Queries Internet name servers interactively. |
| `telnet` | Tests whether a specific TCP port is open. |
| `traceroute` | Prints route IP packets sent to a remote host. |

### `secure-tunnel`

This reference includes examples for the syntax information for the `secure-tunnel` command.

To prevent unwanted cyberattack on the insecure inter-platform communication, VCF Operations for networks provides option to secure the inter-platform communication using IPsec based VPN.

When you enable the secure communication, each platform nodes gets an internal IP addressed assigned from a `/24` subnet. By default, VCF Operations for networks uses `192.168.10.0/24` subnet. You can change the default value of subnet when enabling the secure communication. The subnet must not conflict with any other IP address used for configuring VCF Operations for networks. For example, you must not use IPs from `/24` subnet as an SNMP or an SMTP host configured in VCF Operations for networks.

**Note:**
After you enable the secure communication, you cannot change the subnet. To change the subnet again, you must disable the secure communication and enable it again.

**Note:**
Enabling the secure communication operation can take 15 minutes or more depending size of the cluster. To avoid session time out, you must use the VM console through VMware vCenter UI to run this command.

| Command | Description | Use | Examples |
|---|---|---|---|
| `secure-tunnel` | Enable, disable, check status, assign subnet of secure tunnel | `secure-tunnel {-e,-d,-s, -sub SUBNET}` | `secure-tunnel -e -sub 198.168.0.0/24`<br>`secure-tunnel -d`<br>`secure-tunnel -s` |

**Syntax**

| Flag | Description |
|---|---|
| `-e \| -d \|-s` | Enable secure tunnel, disable secure tunnel, or check status of the secure tunnel |
| `-sub <SUBNET>` | /24 subnet address to use as internal IPs of platforms |

### `services`

This reference includes examples for the syntax information for the `services` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `services` | Starts, stops, or restarts VCF Operations for networks services. | `services {start,stop,restart} {all,launcher-service,nginx,ntp}` | `services start all`<br>`services start nginx`<br>`services stop nginx`<br>`services restart ntp` |

Syntax

| Flag | Description |
|---|---|
| `start \| stop \| restart` | Starts, stops, or restarts the appliance service based on the parameter that you pass. |
| `all \| launcher-service \| nginx \| ntp` | Initiates the action for a particular service or for all services. |

### set-banner

This reference includes examples for the syntax information for the `set-banner` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `set-banner` | Sets the `ssh` banner.<br>Sets the post-login banner for `consoleuser`. | `set-banner [-h] {support,consoleuser} banner` | `set-banner support "Text"`<br>`set-banner consoleuser "Text"` |

Syntax

| Flag | Description |
|---|---|
| `positional arguments:`<br>`{support,consoleuser}`<br>`banner`<br><br>`Quoted text with \n for new line` | Example invocations:<br><br>`(cli) set-banner support "This is a ssh banner. \nRestricted access only!!"`<br>`Successfully set banner!`<br>`(cli) set-banner consoleuser "This is a post-login banner for consoleuser"`<br>`Successfully set banner!`<br>`(cli) logout`<br><br>`# ssh support@10.126.55.193`<br>`This is a ssh banner.`<br>`Restricted access only!!`<br>`support@10.126.55.193's password:`<br><br>`# ssh consoleuser@10.126.55.193`<br>`This is a ssh banner.`<br>`Restricted access only!!`<br>`consoleuser@10.126.55.193's password:`<br>`This is a post-login banner for consoleuser`<br>`(cli)` |

### set-proxy-shared-secret

This reference includes examples for the syntax information for the `set-proxy-shared-secret` command.

| Command | Description | Examples |
|---|---|---|
| `set-proxy-shared-secret` | Configures the platform IP only on the collector VM. | `set-proxy-shared-secret {secret}` |

Syntax

| Flag | Description |
|---|---|
| `secret` | Secret key that the platform interface generates. |

### `setup`

This reference includes examples for the syntax information for the `setup` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `setup` | Used for first time appliance configuration. After deployment when VM is powered on for first time user must use this command to initialize the appliance through VM console. | `setup` | `setup` |

Syntax

| Flag | Description |
|---|---|
| - | No parameters |

### `set-web-proxy`

This reference includes examples for the syntax information for the `set-web-proxy` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `set-web-proxy` | Enables or disables the Web proxy or shows the status of the Web proxy. | `set-web-proxy [--ip IP] [--port PORT] {enable,disable,show}` | `set-web-proxy enable --ip-fqdn "x.y.local" --port 8080 --authtype AUTHTYPE` |

Syntax

| Flag | Description |
|---|---|
| `--ip` | IP address to enable the Web proxy. |
| `--port` | Port number to enable the Web proxy. |
| `enable \| disable \| show` | Enables or disables or displays the configuration settings. |
| `--authtype` | This is optional parameter. Supported authentication types are NTLM or basic.<br>**Note:**<br>HTTPS web proxy is not supported yet. |

### show-service-status

This reference includes examples for the syntax information for the `show-service-status` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `show-service-status` | Shows the status of all VCF Operations for networks services running on the platform or collector VMs. | `show-service-status {debug, cluster}` | `PLATFORM-`<br>`(cli) show-service-status`<br>`ElasticSearch is running.`<br>`HMaster is running.`<br>`HRegionServer is running.`<br>`Kafka is running.`<br>`QuorumPeerMain is running.`<br>`QuorumPeerMain is running.`<br>`ResourceManager is running.`<br>`NodeManager is running.`<br>`restapilayer is running.`<br>`SaasListener is running.`<br>`SamzaAppMaster is running.`<br>`SamzaContainer is running.`<br>`Launcher is running.`<br>`postgresql is running.`<br>`nginx is running.`<br>`patroni is running.`<br>`QuorumPeerMain is running.`<br>`All required services are running.`<br>`QuorumPeerMain is running.`<br>`QuorumPeerMain is running.`<br>`QuorumPeerMain is running.`<br>`QuorumPeerMain is running.`<br>`PROXY-`<br>`(cli) show-service-status`<br>`CollectorMain is running.`<br>`IpfixProcessor is running.`<br>`postgresql is running.`<br>`nginx is running.`<br>`nfcapd is running.` |

Syntax

| Flag | Description |
|---|---|
| `debug \| cluster` | `debug` - displays the health of the services<br>cluster - displays the service status of each node in the cluster |

### show-version

This reference includes examples for the syntax information for the `show-version` command.

| Command | Description |
|---|---|
| `Show-version` | Displays the current version. |

**Table 1321: Usage**

| Command | Description |
|---|---|
| `show-version` | Shows the current version. |
| `show-version history` | Shows upgrade and patch history. |

### `show-config`

This reference includes examples for the syntax information for the `show-config` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `show-config` | Shows the CLI configurations. Displays the CLI console banner, network configurations, and OVA parameters. | `show-config` | `(cli) show-config`<br>`network configurations:`<br>`IP Address:`<br>`192.168.21.55`<br>`Netmask: 255.255.255.0`<br>`Gateway: 192.168.21.1`<br>`DNS nameservers: 4.2.2.4`<br>`8.8.8.8`<br>`Domain Search list:`<br>`arkin.net`<br>`NTP servers:`<br>`0.pool.ntp.org`<br>`1.pool.ntp.org`<br>`2.pool.ntp.org`<br>`3.pool.ntp.org` |

### show-connectivity-status

This reference includes examples for the syntax information for the `show-connectivity-status` command.

| Command | Description | Examples |
|---|---|---|
| `show-connectivity-status` | Displays the connectivity status with all systems. | `(cli) show-connectivity-status`<br>`Platform VM`<br>`Deployment UUID: U12xx08ba-d62e-4745-b73c-9eef6ca9f0b1`<br>`Deployment ID: DXX11XX`<br>`Instance ID: IXXX11X`<br>`Created On: Fri May 19 11:47:23 UTC 2017 (1495194443)`<br>`IP Address: 10.126.102.231`<br>`Netmask: 255.255.252.0`<br>`Gateway: 10.126.103.253`<br>`DNS nameservers: 10.148.20.5 10.148.20.6`<br>`NTP servers: time.vmware.com`<br>`NTP status: InSync [10.113.60.176/2/377]`<br>`Gateway ping status: Success`<br>`Upgrade connectivity status (svc.ni.vmware.com:443): Passed`<br>`Support connectivity status (support2.ni.vmware.com:443): Enabled`<br>`Logserver connectivity status (log.ni.vmware.com:443): Passed`<br>`Registration connectivity status (reg.ni.vmware.com:443): Passed`<br>`Registration status: Registered` |

### ssh-service

This command enables or disables the SSH service.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `ssh-service` | Enables or disables the SSH service | `ssh-service [-h] {status,enable,disable}` | `ssh-service status`<br>`ssh-service enable`<br>`ssh-service disable` |

**Table 1322: Syntax**

| Flag | Description |
|---|---|
| `enable \| disable \| status` | Enables or disables the service or provides the status of the service. |

### support-bundle

This reference includes examples for syntax information for the `support-bundle` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `support-bundle` | Provides support related logs for debugging. | `support-bundle [-h] {list,create,delete,copy}` | |

Syntax

| Flag | Description |
|---|---|
| `list` | Lists all support bundles created so far.<br>Example:<br>`support-bundle list` |
| `create` | Creates a support bundle to be shared for debugging.<br>Example:<br>`support-bundle create` |
| `delete` | Deletes specific or all bundle files.<br>Example:<br>`To delete a specific bundle file:`<br>`support-bundle delete --bundle DOAUAAO-IOAUACW-07252016-162328`<br>`To delete all bundle files:`<br>`support-bundle delete` |
| `copy` | SCP to any host for sharing with the support team.<br>Example:<br>`support-bundle copy --user support --ip 192.168.1.1 --port 22 --bundle DOAUAAO-IOAUACW-07252016-162328 --targetpath /tmp` |

### `tool-manager`

This reference includes examples for syntax information for the `tool-manager` command.

| Command | Description |
|---|---|
| `tool-manager` | Helps to run the tool |

**Table 1323: Usage**

| Command | Description |
|---|---|
| `tool-manager copy scp --host <IP> --user <username> --path <tool bundle file absolute path>` | Copy the tool bundle to VCF Operations for networks Platform/ collector |
| `tool-manager run --name <tool name>` | Run the tool |
| `tool-manager run [-h] --name <tool name>` | |
| `tool-manager copy url` | |

**Table 1324: Example**

| Command |
|---|
| `tool-manager copy scp --host 192.168.21.18 --user ubuntu --path /home/ubuntu/patch-online-upgrade-3.0.0_201609151002.bundle` |
| `tool-manager run --name patch-online-upgrade-3.0.0_201609151002` |
| `tool-manager copy url https://bundle-hosting-url.com/patch.bundle` |

Syntax

| Flag | Description |
|---|---|
| `--host` | IP address, where upgrade bundle is downloaded from VMware download portal. Upgrade bundle should be downloaded on any Linux machine from where the bundle can be scp to VCF Operations for networks platform or collector. |
| `--user` | User, who can be used to authenticate the Linux machine. |
| `--path` | Source path where the bundle is downloaded from VMware portal on Linux Machine. |
| `--port` | (Optional) - In case ssh port on Linux machine running other than port 22. |

### `traceroute`

This reference includes examples for syntax information for the `traceroute` command.

| Command | Description | Usage | Example |
|---|---|---|---|
| `traceroute` | Prints route IP packets sent to a remote host for the host that you provide as the parameter. | `traceroute host` | `traceroute examples.com` |

Syntax

| Flag | Description |
|---|---|
| `host` | Name of the host such as `example.com`. |

Related Commands

| Command | Description |
|---|---|
| `nslookup` | Queries Internet name servers interactively. |
| `telnet` | Tests whether a specific TCP port is open. |
| `traceroute` | Prints route IP packets sent to a remote host. |

### `update-IP-change`

This reference includes examples for syntax information for the `update-IP-change` command.

| Command | Description | Usage | Examples |
|---|---|---|---|
| `update-IP-change` | Update Platform configuration after IP Address change on other Platforms in a cluster | `update-IP-change [-h] old_ip new_ip` | `update-IP-change 192.168.1.10 192.168.1.100` |

Syntax

| Flag | Description |
|---|---|
| `old_ip` | Old IP of Platform |
| `new_ip` | New IP of Platform |

### `pair-collector`

This reference includes examples for the syntax information for the `pair-collector` command.

| Command | Description |
|---|---|
| `pair-collector` | Checks the current pairing status with Platform or updates Platform's IP/FQDN if it is changed.<br>**Note:**<br>You cannot point an existing Collector to a new Platform. |

**Table 1325: Syntax**

| Flag | Description |
|---|---|
| `set-platform` | Resets updated Platform IP/FQDN. |
| `platform-pair-status` | Shows Platform and Collector pairing status. |

**Table 1326: Example**

| Command | Sample Query |
|---|---|
| For ONPREM: `pair-collector set-platform --ip-or-fqdn <IP address>` | `pair-collector set-platform --ip-or-fqdn 192.168.10.12` |
| For SaaS: `pair-collector set-platform --ip-or-fqdn <FQDN>` | `pair-collector set-platform --ip-or-fqdn platform.exampledomain.com` |
| `pair-collector platform-pair-status` | `pair-collector platform-pair-status` |

## Creating and Expanding Clusters

### Create Clusters

You can create clusters from the **Settings** > **Infrastructure and Support** > **Infrastructure and Updates** page.

**Prerequisites**

At least two additional platforms are required. The additional platform VMs should be deployed and powered on.

**To create cluster**

1. Click **CREATE CLUSTER** for **Platform VMs**.
2. On the **Create Cluster** page, enter the following information:
   - **IP Address**: Enter the IP address of the new platform that you want to add. VCF Operations for networks supports both IPv4 and IPv6 addresses.
   - **Password**: Enter the support user password of the platform VM. If you have not changed the password yet, then refer the *Default Login Credentials* section in *VCF Operations for networks Installation Guide* for the password.
3. To keep adding more platforms, click **Add more** and enter the IP address and the support user password.
4. Click **SUBMIT**. Click **Yes**.
5. After creating a cluster, the user needs to log in to the product again.

**Note:**

- The **CREATE CLUSTER** option is enabled only when the platform is of large brick size. All platforms should be of large brick to create cluster.
- To expand clusters, refer the *Expanding a Cluster* section in the *VCF Operations for networks Installation Guide*.

### Expand or Scale Out Clusters

Once the cluster is created, you can expand or scale out the cluster by adding more platform nodes to it.

**Note:**

- Before you scale up the cluster, you must take a backup of the cluster. For more information about the backup and restore process, see the KB 55829.
- You must perform the expand cluster operation only from Platform 1 (P1) node.

1. Go to **Settings** > **Infrastructure and Support** > **Infrastructure and Updates**.
2. On the **Infrastructure and Updates** page, click **EXPAND CLUSTER** for **Platform VMs**.
3. The IP addresses of the VMs that are part of the cluster already are listed on the **Expand Cluster** page. To add one or more nodes to the existing cluster, provide the IP address (IPv4 or IPv6 address) of the node and the support user password.

   **Note:**

   - Currently, VCF Operations for networks supports 15 nodes in an existing cluster. Once the limit is reached, the **Add more** button is deactivated.
   - Ensure that all the new nodes do not have license keys applied (non-provisioned) and are reachable through SSH.
   - Ensure that you have taken a backup of the existing platform VMs before you go ahead with the cluster expansion.
4. Click **SUBMIT**.

   The step-by-step progress is displayed.
5. Once the cluster expansion link is completed, a message indicating success is displayed.

   While the cluster expansion is in progress, the application cannot be used for any other operation.

If you are on the Deployment Scenario 2, then you must reconfigure your platform. To reconfigure, on the **Infrastructure and Updates** page, under in **Platform Capacity** section, click the **RECONFIGURE** button.

**Note:**
The **RECONFIGURE** button appears only when your platform needs reconfiguration.

**Note:**

For information on deployment options and the other system requirements, see System Recommendations and Requirements.

## Configuring VCF SSO for VCF Operations for networks

To use VCF Single-Sign On (SSO) in VCF Operations for networks, you must configure it manually.

As an administrator, you can configure SSO to streamline access to VCF Operations for networks. After configuration, you can select SSO as you log in method.

1. Log in to VCF Operations for networks with your local account.
2. To begin creating a SSO configuration, click **Configure**.

   The **Identity and Access Management** page opens.

3. Select the VCF SSO option.
4. Enter the identity broker issuer address, client ID, and client secret details.
5. Click **Test Connection**.
6. To finish configuring SSO, click **Submit**.

After configuring SSO, you can now log in using this streamline method by selecting the SSO configuration from the **Login Method** drop-down. For more information on configuring VCF SSO, see *Configuring VCF Single-Sign On* in the fleet management documentation.

**Note:**

If the IP address is changed, it is recommended that you regenerate the SSO configuration and save the change. Additionally, if a user is added to SSO group and then that group is deleted, the user can no longer log in to VCF Operations for networks. To restore access, the administrator must restore the deleted user role.

## Network Assessment and Value Analysis

Powered by VCF Operations for networks, the **Network Assessment and Value** dashboard in VCF Operations allows you to evaluate and optimize your networking capabilities by adopting VCF networking.

- To use the **Flows** tab, verify that you have installed VCF Operations for networks. Using the **Metrics** tab does not require installing VCF Operations for networks.
- Verify that Network Flow Collection is configured.

By performing a network assessment analysis on your vCenter networking capabilities, you can receive an overview of the projected benefits of adopting VCF networking capabilities. The benefits of the network assessment include:

- Visualizing the Capital Expenditures (CapEx) and Operational Expenditures (OpEx) savings you can make by switching to VCF networking.
- Quantify the Total Cost of Ownership (TCO) of your networking infrastructure.
- Show the simplification and optimization benefits of VCF networking.

This assessment focuses on deployments with only virtual networking (VDS). Existing VPC networking configuration is not taken into account in the assessment.

1. Navigate to **Operate** > **Network Inventory** and select **Network Assessment and Value** from the **Virtual Networking** widget.

   Alternitavely, you can also access this feature in VCF Operations by navigating to **Manage** > **Plan** > **What-If Analysis**.
2. Select **Start Network Assessment**.
3. Select the vCenter instance which includes your networking resources and click **Run Assessment**.

   **Note:**

   If you have multiple vCenter instances, you must run a seperate assessment for each instance.

You are shown the **Network Assessment and Valu**e dashboard. The two tabs on the dashboard, **Metrics** and **Flows**, show an assessment of your current vCenter networking capabilities and the projected improvements that you can expect if you migrate to VPC networking. Data included in the assessment include:

- The mobility score of your network infrastructure, which indicates the projected capability to move networking workloads across your data center.
- Compute and memory utilization of your network infrastructure.
- The TCO of your vCenter networking infrastructure and the potential savings of switching to VCF networking.
- Visualization of your current vCenter infrastructure, including VDSs, number of hosts, and clusters and projected infrastructure converted to NSX VPCs.

When using the dashboard, the following functionality must be considered:

- The Projected Mobility Score is always 100% (not computed), because VPC subnets span across all clusters in the domain.

- If the current CPU and Memory Utilization is under 50% and there is host reduction opportunity through workload rearrangement, then projected values are set to 50%. Otherwise, the values remain as they are currently.
- The projected host count is computed at the individual cluster level. Host reduction opportunity across clusters because of a improved Mobility Score is not considered in the projected host count and Potential Savings calculation.
- Low PNIC Bandwidth Utilization might be displayed as 0% because of a value rounding off.
- Unlike other What-If Analysis items, Network Assessment and Value results cannot be saved.

### VPC Planning

After performing a network assessment, you can begin preparing your network infrastructure for migration to VPCs by performing a VPC planning operation.

You must perform a separate VPC planning operation for each vCenter instance in your environment.

1. Navigate to **Operate** > **Network Inventory** and select **VPC Planning** from the **Virtual Networking** widget.

   Alternatively, you can also access this feature in VCF Operations by navigating to **Manage** > **Plan** > **What-If Analysis**.
2. Select your vCenter instance and click **Proceed**.
3. Select a Virtual Distributed Switch (VDS) from your vCenter instance and click **Proceed** to perform the VPC planning operation.

   **Note:**

   You can view detailed information for each Distributed Virtual Port Group (DVPG) in your VDS by selecting the entry in the **Number of Port Groups** column.
4. After the operation is complete, you are shown a list of the recommended VPCs, the suggested subnet, Gateway CIDR IPv4 address, and number of VMs in that subnet.

   For more information on VMs in the suggested subnet, select the entry in the **Number of VMs** column.
5. To export the results of the VPC planning operation, click **Export to .CSV File**.

## About Backing up and Restoring of VCF Operations for Networks Deployment Data

You can take a backup of the VCF Operations for networks data and restore data in a new deployment when the existing setup is unrecoverable. And also, you can replicate the setup configuration on multiple deployments.

Starting from the 6.0 release, VCF Operations for networks enables you to take a backup of the following data:

- Configuration defined under **Settings** option on the UI
  - CEIP status
  - Data manangement (retention interval)
  - IP Properties and Subnet configuration
  - Identity and Access management
  - Syslog configuration
  - Personally Identifiable Information status in Audit logs
  - Mail Server and SNMP configuration
  - System configurations like User Session Timeout, Certificate Validation, Google Maps API key.
  - User preferences like dark theme, dashboard auto refresh.
- Datasources added to the setup, except for Physical Flow Collector (Netflow, sFlow).
- Alerts which includes system alerts, user-defined alerts, platform health

You can store the backup on the local storage, which can store up to five latest backup files. And also you can upload the backup to SSH or FTP servers.

**Note:**

- VCF Operations for networks takes a backup of the above mentioned configuration data only, and not the complete setup data, like flows or application information.

- You can track any failure in the backup or restore process on the **Infrastructure** page (**Settings** > **Infrastructure and Support** > **Overview and Updates** > **Infrastructure** > **Overall Health section** ).
- You can also configure an alert notification for the backup failure under Platform Health Alerts.

## Backup and Restore of VCF Operations for Networks

In VCF Operations for networks, you can store the backup on the local storage (up to five latest backup files), SSH or FTP servers. You can start the backup immediately or schedule a periodic backup.

- The backup and restore setups must have identical versions.
- To avoid any inconsistencies, the restore setup must be a fresh deployment. Take the snapshots of the VMs before you run the restore commands.
- Only **Admin** and **Console** users can configure backup and restore through public APIs and CLI commands respectively. The **Auditor** user can only see if any backup and restore configuration exists on the setup.

1. Start the backup process.

| Method | Description |
|---|---|
| **Using CLI command** | `backup-restore backup --action add --path <config-file-path>`<br><br>Create a backup configuration file on one of the platform nodes under `/home/ubuntu`. To create the file, you must login as **Support** user.<br><br>**Note:**<br>To run the CLI commands, you must log in as a **Console** user on the same platform where you created the backup configuration file. |
| **Using API** | See **settings/backup** on the API Reference page.<br><br>**Note:**<br>You must provide the configuration as the JSON body in the API request. |

**Table 1327: Configurations for the backup process**

| Scenario | Description | File Configuration |
|---|---|---|
| Configuration to trigger backup | Creates the backup file on local file server in the default directory: `/var/lib/backup-restore` or, any user specified backup directory | `{"backup_file_server_type":"LOCAL"}`<br>or<br>`{"backup_file_server_type": "LOCAL",`<br>`"local_file_server":`<br>`{`<br>`"backup_directory": "backup_directory_path"`<br>`}`<br>`}` |
| | Creates the backup on FTP server in the user specified backup directory | `{`<br>`"backup_file_server_type": "FTP",`<br>`"ftp_file_server":`<br>`{`<br>`"server_address": "IP address",`<br>`"port":port_number,`<br>`"username": "username",`<br>`"password": "password",`<br>`"backup_directory": "backup_directory_path"`<br>`}`<br>`}` |

| Scenario | Description | File Configuration |
|---|---|---|
| | Creates the backup on SSH server in the user specified backup directory | <pre>"backup_file_server_type": "SSH",<br>"ssh_file_server":<br>{<br>"server_address": "*IP address*",<br>"port":*port_number*,<br>"username": "*username*",<br>"password": "*password*",<br>"backup_directory": "backup_directory_path"<br>}</pre> |
| Configuration to schedule the backup process | Immediate Backup | <pre>"schedule_now": true,</pre> |
| | Daily Backup<br>The permissible value for `hour` : 0-23 The permissible value for `minute` : 0-59 | <pre>"backup_schedule":<br>{<br>"schedule_period": "DAILY",<br>"hour": 16,<br>"minute": 51<br>},</pre> |
| | Weekly Backup<br>The permissible value for `hour` : 0-23 The permissible value for `minute` : 0-59 The permissible value for `day_of_week` : 1(Sunday) - 7 (Saturday) | <pre>"backup_schedule":<br>{<br>"schedule_period": "WEEKLY",<br>"hour": 16,<br>"minute": 56,<br>"day_of_week": 3<br>},</pre> |
| Backup only few configurations | In the `data_filter` parameter of the configuration file, set the configuration to `true` to backup selected configurations. To skip the backup of a particular configuration, set the value to `false`.<br>**Note:**<br>If you do not specify the `data_filter` parameter, VCF Operations for networks backs up all the configurations. | <pre>"data_filter":<br>{<br>"snmp": true,<br>"smtp": true,<br>"web_proxy": false,<br>"data_sources": false,<br>"events": false,<br>"syslog": true,<br>"ldap": true,<br>"vidm": true,<br>"user_data": true,<br>"physical_subnet_vlan": true,<br>"physical_ip_dns_mapping": true,<br>"system_configuration": true,<br>"east_west_ip": false,<br>"north_south_ip": true,<br>"data_management": true,<br>"online_update_status": true,<br>"ceip_status": true,<br>"audit_logs_pii_status": false<br>}</pre> |

An example of the configuration file for a weekly backup (every Tuesday) on a FTP server with selected configurations.

```
{
"backup_schedule":
  {
      "schedule_period": "WEEKLY",
      "hour": 16,
      "minute": 56,
```

```
        "day_of_week": 3
    },
  "backup_file_server_type": "FTP",
  "ftp_file_server":
    {
        "server_address": "10.125.48.146",
        "port": 22011,
        "username": "testuser",
        "password": "password!",
        "backup_directory": "/backup"
    },
  "data_filter":
    {
        "snmp": true,
        "smtp": true,
        "web_proxy": false,
        "data_sources": false,
        "events": false,
        "syslog": true,
        "ldap": true,
        "vidm": true,
        "user_data": true,
        "physical_subnet_vlan": true,
        "physical_ip_dns_mapping": true,
        "system_configuration": true,
        "east_west_ip": false,
        "north_south_ip": true,
        "data_management": true,
        "online_update_status": true,
        "ceip_status": true,
        "audit_logs_pii_status": false
    }
  }
```

2. Trigger the restore process.

   The sequence for restore is as follows:

| Method | Description |
|---|---|
| **Using CLI commands** | `backup-restore restore --action add --path <config-file-path>`<br><br>Create a restore configuration file on one of the platform nodes under `/home/ubuntu`. To create the file, you must login as **Support** user.<br><br>**Note:**<br>To run the CLI commands, you must log in as a **Console** user on the same platform where you created the restore configuration file. |
| **Using API** | See **settings/restore** on the API Reference page.<br><br>**Note:**<br>You must provide the configuration as the JSON body in the API request. |

**Table 1328: Configurations for the restore process**

| Scenario | Description | File Configuration |
|---|---|---|
| Configuration to trigger restore | Restores from the local file server | { "backup_file_server_type": "LOCAL", "local_file_server": { "backup_directory": "backup_directory_path", "backup_file_name": "file_name.tar" } } |
| | Restores from the FTP file server | { "backup_file_server_type": "FTP", "ftp_file_server": { "server_address": "*IP address*", "port":*port_number*, "username": "*username*", "password": "*password*", "backup_directory": "backup_directory_path" "backup_file_name": "file_name.tar" } } |

| Scenario | Description | File Configuration |
|---|---|---|
| | Restores from SSH file server | "backup_file_server_type": "SSH",<br>"ssh_file_server":<br>{<br>"server_address": "*IP address*",<br>"port":*port_number*,<br>"username": "*username*",<br>"password": "*password*",<br>"backup_directory": "backup_directory_path"<br>"backup_file_name": "*file_name.tar*"<br>} |
| Restore only few configurations | In the data_filter parameter of the configuration file, set the configuration to true to restore selected configurations. To skip the restore of a particular configuration, set the value to false.<br>**Note:** If you do not specify the data_filter parameter, VCF Operations for networks restores all the configurations. | "data_filter":<br>{<br>"snmp": true,<br>"smtp": true,<br>"web_proxy": false,<br>"data_sources": false,<br>"events": false,<br>"syslog": true,<br>"ldap": true,<br>"vidm": true,<br>"user_data": true,<br>"physical_subnet_vlan": true,<br>"physical_ip_dns_mapping": true,<br>"system_configuration": true,<br>"east_west_ip": false,<br>"north_south_ip": true,<br>"data_management": true,<br>"online_update_status": true,<br>"ceip_status": true,<br>"audit_logs_pii_status": false<br>} |

**Note:**
If you do not specify the collector_mapping parameter, all the restored data sources will be mapped to a random collector on the restore setup.

```
"collector_mapping": {
"default_collector": "default_collector_ip",
"mappings": [
{
  "source": "source_collector_ip",
  "destination": "destination_collector_ip"
}
]
}
```

If you specify collector_mapping, all data sources mapped to source_collector_ip on the backup setup will be mapped to destination_collector_ip on the restore setup. If mapping is not specified for any collector on the backup setup, the corresponding data sources will be mapped to the default_collector on the restore setup. You can specify mapping for multiple source collectors to destination collectors.

An example of the configuration file to restore from a FTP server with selected configurations.

```
"backup_file_server_type": "FTP",
"ftp_file_server":
  {
      "server_address": "10.120.18.146",
```

```
        "port": 22011,
        "username": "testuser",
        "password": "Password!",
        "backup_directory": "/backup"
        "backup_file_name": "vrni_backup-19801-10.79.197.0-2020-08-26-06.56.44.tar"
    },
  "collector_mapping":
    {
        "default_collector": "10.120.135.2",
        "mappings":
            [
            {
            "source": "10.134.135.3",
            "destination": "10.120.2.120"
            }
            ]
    },
  "data_filter":
    {
        "snmp": true,
        "smtp": true,
        "web_proxy": false,
        "data_sources": false,
        "events": false,
        "syslog": true,
        "ldap": true,
        "vidm": true,
        "user_data": true,
        "physical_subnet_vlan": true,
        "physical_ip_dns_mapping": true,
        "system_configuration": true,
        "east_west_ip": false,
        "north_south_ip": true,
        "data_management": true,
        "online_update_status": true,
        "ceip_status": true,
        "audit_logs_pii_status": false
    }
  }
```

## VCF Operations Integration

With VCF Operations, you can see the VCF Operations for networks alerts in VCF Operations. And also, you can see the network information in VCF Operations from VCF Operations for networks.

VCF Operations consumes a set of VCF Operations for networks APIs and displays lists of alerts on the Alerts Dashboard. You can identify the VCF Operations for networks alerts with the `vrni-` prefix in the alert names. In addition, you can see the entity on which the alert was triggered.

You can use the **Launch-in-context** option from the entity pages, such as VMs, Hosts, and NSX-T, so you can view the dashboard of that particular entity. This enables you to see the network health and to debug a network issue.

For information about supported VCF Operations versions, see VMware Product Interoperability Matrix.

> **Note:**
> You must add the VCF Operations user into VCF Operations for networks and provide at least **Member** privileges for the user to use this feature in VCF Operations.

# Configuring Flows in VCF Operations for networks

You can use VCF Operations for networks to configure flows to transmit various network data.

## Frequently Asked Questions for IPFIX

Familiarize yourself with core concepts of using IPFIX in VCF Operations for networks.

### What are the VCF Operations for networks IPFIX configuration limits and requirements?

For information on the VCF Operations for networks IPFIX configuration, see VCF Operations for Networks System Recommendations and Requirements.

### What communication protocols are supported?

VCF Operations for networks IPFIX supports the TCP and UDP protocols. Other protocols, such as ICMP, are not supported.

### Does VCF Operations for networks support de-duplication and aggregation of flows from multiple sources?

Yes, de-duplication and aggregation are supported. The same data reported from multiple sources is de-duplicated and the best metric among all the sources is considered for flow analysis. Different attributes from multiple sources are also aggregated and shown in the flow information.

### What happens if the TCP handshake Is unsuccessful?

Handshakes are only performed for TCP, UDP does not require this validation. If the handshake is unsuccessful, the flow is rejected. Currently, VCF Operations for networks only checks for VDS and NSX flows. Other flows do not report TCP flags and as a result, the check cannot be completed. If VDS reports the TCP handshack as unsuccessful for a specific flow, the NSX or physical counterpart is also rejected.

### What are the outbound flow limits?

The number of connections a client can make in VCF Operations for networks is limited. Flows are dropped if this limit is exceeded. This is a protection mechanism to make sure any non-flow entities, such as scanners which scan every machine in the environment, do not overwhelm the total flow limit.

| Protocol Type | Limit for Allowed Flows | Limit for Denied Flows |
|---|---|---|
| TCP | 1000 | 50 |
| UDP | 500 | 50 |

### What are the inbound flow limits?

Limit on the number of external flows in the environment. The inbound limit covers the number of external flows in the environment. This limit ensures that the external flows do not overwhelm the overall flow limit in VCF Operations for networks . When this limit is exceeded, new incoming flows are aggregated with the following client IPs:

- For allowed external flows: 240.240.240.240
- For denied external flows: 240.240.240.241

| Limit Type | Limit for Allowed Flows | Limit for Denied Flows |
|---|---|---|
| Limit per service endpoint | 5000 | 50 |
| Global limit | 500000 | 100000 |

### What can cause dropped flows?

Dropped flows are flows that are not picked up by the VCF Operations for networks collector. Flows can be dropped for the following reasons:

- The wrong reporting point is used. For NSX flows, the flow can be reported from multiple places. VCF Operations for networks only processes flow data reported from either source or destination of the flow. All other flow records are ignored.
- The TCP handshake is unsuccessful.
- The outbound or inbound limits are reached.
- Incompatibility between the flow and collector. For example, non-physical flows are directed to a dedicated physical collector.

### Why is port information aggregated?

Port aggregation is built in to aggregate the ephemeral port flows, such as dynamic FTP, Oracle, MS-RPC, and others. Aggregation helps in reducing the number of flows in the system and provides an summarized view for a large number of flows that are essentially for the same service.

### How does port aggregation work?

Port aggregation is based on the following workflow:

1. For the first three days of having a destination IP be recorded, VCF Operations for networks aggregates the destination ports of that IP in buckets of 10K and starts building a port profile for the IP.
2. After the intial three day period, port aggregation is started in ranges where the port density is high. High port density is selected as this is representative of the ephemeral port opening pattern. The ranges can be dyanmic in size (100, 1000, or 10K) and are created depending on how many ports are opened and how widespread they are in the specific aggregation range. This allows high-port flows to be reported with no aggregation where there is no bulk port open activity happening. It also allows the application of dynamic aggregation.

   **Note:**

   The aggregation range is specific for each server IP address.
3. The profile is continually updated in a time-decayed manner to account for new ports opening up or older ports are not used anymore.

### Why do I see port aggregation for a port where there is no bulk activity?

VCF Operations for networks performs a blanket aggregation of port 1024 when it gets reported for the first time. This aggregation is done to reduce the number of flows in the system initially. After the port profile is built, this aggregation is removed, if there is no bulk port opening activity happening.

### When is a flow closed?

A specific flow entry is closed when VCF Operations for networks does not receive any IPFIX data for the 5-tuple parameters (protocol, source IP, source port, destination IP, and destination port) after a time duration of 25 hours.

### Can a splitter be used to send flows to multiple collectors?

Yes, if the collector limit is reached, a splitter can be used. You must configure the splitter to ensure that the flow for a 4-tuple parameters (source IP, source port, destination IP, and destination port) is sent to a specific collector. Sending the same 4-tuple to different collectors, can cause incorrect metric data to be shown.

### How long does it take to see the flow information after adding a data source?

It usually takes three or four hours for flow information for a newly added data source to start being displayed.

### Why do I see stale firewall rules on flows?

Duplicate flows can be caused by the following scenarios:

- When a firewall rule changes from rule 1 to rule 2. When the change occurs, VCF Operations for networks does not immediately remove the old firewall rule. There is a time window of six hours before the old rule is removed. So, for a maximum of six hours, you can see both rules. The scope of this temporary duplication can increase if more firewall rules are changed in a short amount of time.
- For NSX-T Federation, multiple rules can be applied to flow. For example, one by the Global Manager and another by the Local Manager.

### How is the client and server for a flow determined?

The client and server are dependent on the communication protocol which is used.

For TCP:

- DFW: the directionality is already determined by DFW, and the source and destination of the flow are set corresponding to the client and the server
- VDS: for a TCP connection, the information about the SYN packet sent by the client is reported in a separate IPFIX flow record by the VDS. This IPFIX flow record is used to decide the client and server for a connection. There might be a situation when VCF Operations for networks does not receive the IPFIX packet. This can happen if this IPFIX packet is lost (IPFIX is sent over UDP), or if VCF Operations for networks identifies a long-lived flow which can be terminated because of a period of inactivity. In this case, VCF Operations for networks determines the client and server for a connection by using the source and destination port numbers. The client port is assumed to be greater than the server port.
- OTHERS: for a TCP connection, if the SYN packet sent by the client is reported in a separate IPFIX flow record by the exporter then same approach as VDS is used. Otherwise, VCF Operations for networks determines the client and server for a connection by using the source and destination port numbers. The client port is assumed to be greater than the server port.

For UDP:

- DFW: the directionality is already determined by DFW, and the source and destination of the flow are set corresponding to the client and the server by DFW.
- OTHERS: if only one direction of IPFIX flow records is found, then consider that direction as the flow direction (source is the client and the destination is server) Otherwise, VCF Operations for networks determines the client and server for a connection by using the source and destination port numbers. The client port is assumed to be greater than the server port.

### What is the flow count for a data source page and how is it determined?

The numbers shown on the data source page show the unique flows (4 tuples) seen from the data source in last 24 hours. The value is updated regularly (every ~5 minutes). The number can change since it only considers flows in the moving window of the last 24 hours. The count should match the results of the following query: `'count of flows where reporter = <Data Source>'`

### How are session counts measured?

If the flow is inactive for more than 2 minutes, then VCF Operations for networks considers that the session is completed for that 5-tuple. This is done at the 5-tuple level. VCF Operations for networks shows the flow in the UI with an aggregated 4-tuple generated from the 5-tuple (the source port is dropped). If the source port is changed frequently, each 5-tuple is considered as a separate session. Session counts across a 5-tuple are aggregated to a single 4-tuple.

### What is the overall limit on the number of flows?

The overall flow limits are documented in VCF Operations for Networks System Recommendations and Requirements. If VCF Operations for networks exceeds these limits, the oldest flows are overwritten. Addtionally, if the flow limit is exceeded on the collector side, then the flow data is dropped on the collector itself until the number of flows goes back to the defined limit. Exceeding flow limits can cause gaps for existing flow data or missed data on new flows.

**Are flows that are dropped or rejected by DFW supported?**

Yes, flows dropped or rejected by DFW are supported.

**Why am I not receiving flows even after activating flow collections on the data source or receiving flows after flow collection is deactivated?**

In VCF Operations for networks 9.1 and later, it might take 10 minutes to reflect configuration changes. This delay is valid for both newly configured flow collections and flow collections that are recently deactivated.

## Enabling IPFIX Configuration

IPFIX is an IETF protocol for exporting flow information.

A flow is defined as a set of packets transmitted in a specific timeslot, and sharing the same 5-tuple values - source IP address, source port, destination IP address, destination port, and protocol. The flow information may include properties such as timestamps, packets/bytes count, Input/Output interfaces, TCP Flags, VXLAN ID, Encapsulated flow information, and so on.

> **Note:**
>
> VCF Operations for networks does not display geolocation information included in flows. Contact Broadcom support for assistance.

### IPFIX Configuration on VDS and DVPG

A Virtual Destributed Switch (VDS) in a vSphere environment can be configured to export flow information using IPFIX

Flow monitoring has to be activated on all port groups attached to the VDS. If the packets arrive on port X of a VDS and exit from port Y, a corresponding flow record is sent if flow monitoring is enabled on port Y.

To analyze the complete information of any session, the IPFIX data about packets in both the directions is required.

> **Note:**
>
> Starting with VCF 9.1, activating uplink DVPG connections is no longer supported. The relevant option in the IPFIX configuration for vCenter data centers is deactivated.

VCF Operations for networks collector VM has built-in collector/receiver for IPFIX flow information. You can enable the IPFIX information collection in the VMware vCenter data source settings at various levels of granularity.

**Enable IPFIX Configuration on VDS and DVPG**
To use IPFIX, you must activate the relevant option for your VMware vCenter data source.

1. Select the **Enable NetFlow (IPFIX) on this vCenter** check box when you are adding VMware vCenter in VCF Operations for networks.

   > **Note:**
   >
   > To enable Antrea IPFIX for collection of Supervisor, namespace, and VKS cluster flows, select **Enable Antrea (IPFIX) on this vCenter**.

   You see list of all the available VDS.
2. Select the VDS for which you want to enable IPFIX from the list of available VDS in VMware vCenter.
3. A notification icon is displayed for the VDS where one of the hosts has unsupported version of ESX. If VCF Operations for networks has detected that IPFIX is already configured for a VDS with some other IP address apart from VCF

Operations for networks collector VM, then it displays the **Override** button. Click **Override** to view the list of DVPGs under that VDS.

4. The list of available DVPGs for the selected VDS is displayed. All the DVPGs are selected by default. Turn **Manual Selection** on to select specific DVPGs for which you want to enable IPFIX. Select the desired DVPGs and click **Submit**.

## Using Antrea IPFIX for VKS Flows

By using Antrea IPFIX, you can collect and analyze data about VMware vSphere Kubernetes Service (VKS) flows from your data sources.

- Verify that VCF Operations for networks is deployed.
- Verify that your vCenter data source version is 9.1 or later.
- Verify that your vCenter data source is not added to multiple VCF Operations for networks deployments or that the Antrea IPFIX management services have a different collector assigned to them from the collector currently configured in VCF Operations.
- Verify that your VKS version is 3.5.1 or later.
- Verify that the `AntreaIPFIX` property is activated in the Antrea configuration for each VKS cluster you want to export flows from. To activate the property, you must set its value to `true` in either the `AntreaConfig` (VKS 3.5.1) or the `AddonConfig` (VKS 3.6.0 or later) file. The following is a sample code for activating the property on a VKS 3.6.0 cluster:

```
apiVersion: addons.kubernetes.vmware.com/v1alpha1
kind: AddonConfig
metadata:
  name: ${clustername}-antrea
spec:
  addonConfigDefinitionRef:
    name: antrea.tanzu.vmware.com.2.5.0---vmware.1-tkg.1
    namespace: vmware-system-vks-public
  clusterName: ${clustername}
  values:
    antreaIPFIX:
      enable: true
```

- Verify that you have enabled **Enable Antrea (IPFIX) on this vCenter** in your vCenter data source in VCF Operations.

**Note:**

After enabling the IPFIX option in your data source, you can aslo verify that flow collection is enabled by navigating to the Supervisor cluster in vCenter. Navigate to **Network** > **Management Proxy Configuration** and verify that the **netops-vks-api-proxy** and **netops-antrea-flows** management services are available.

VCF Operations for networks allows you to perform an analysis on VKS flows, such as Kubernetes clusters, pods, and services. You can use this flow information to analyze and troubleshoot your networking infrastructure. For more information on VKS, see Managing vSphere Kubernetes Service Clusters and Workloads.

**Note:**

Antrea IPFIX flow collection currently has the following limitations:

- Supervisor VDS Networking stack is not supported.
- Flow collection is stopped if the corresponding NSX data source is not added to VCF Operations for networks.
- The vCenter and NSX data sources associated with the VKS clusters must be added to the same VCF Operations for networks collector.
- Pod-to-Service flows where the destination VIP is the load balancer IP and not the cluster IP are not supported.
- IPv6 flows are not supported.
- External-to-Pod flows are not supported.

1. In VCF Operations, navigate to **Operate** > **Flows**.
2. Under **Scope**, you can select the scope of the flow analysis.
3. If you defined to scope of the flow analysis, select the type of VKS flow data, for example, **Kubernetes Cluster**, which you want to add to the analysis.

   The **Network Policy** type includes the Antrea cluster network policy, Antrea network policy, and Kubernetes network policy flows.
4. In the search box, select the VKS flow entities that you want to analyze.

   To view the relevant flows for the selected entities, click **View All Flows**.
5. To collect the flow data for the selected entity types, click **Analyze**.

The flow data is presented in the **Top Talkers**, **Recent Flows**, **Network Performance**, **Pod Network Traffic, Network Policy**, and **Node Throughput** tabs.

## NSX IPFIX Configuration

NSX IPFIX provides network monitoring data similar to that provided by physical devices and gives administrators a clear view of virtual network conditions.

NSX virtualizes the network by allowing the network administrator the ability to decouple the network from physical hardware. This functionality makes it easy to grow and shrink the network as needed and making the network transparent to the applications traversing it.

By using NSX IPFIX in a virtualized network, the network administrators gain visibility into the virtual overlay network. It provides visibility on the VTEP that is encapsulating the packet, and the details of the VM that generated the inter-host traffic on an NSX Logical Switch (VXLAN).

The distributed firewall implements stateful tracking of flows. As these tracked flows go through a set of state changes, IPFIX can be used to export data about the status of that flow.

The tracked alerts include flow creation, flow denial, flow update, and flow teardown. The denied alerts are exported as syslogs.

> **Note:**
>
> If vCenter is added as compute manager to NSX, VDS does not export TCP flags in IPFIX flow records. VCF Operations for networks drops such flows.

Starting with VCF 9.1, VDS IPFIX supports TCP retransmission count and round-trip time (RTT) flow metrics for NSX. For more information, see Flow Metrics.

### Enable NSX-T IPFIX

In VCF Operations for networks, you can view DFW or Switch IPFIX flows. For this, you must enable IPFIX flows in the NSX-T data source.

- Ensure that you have any one of the following privileges:
  - `enterprise_admin`
  - `network_engineer`
  - `security_engineer`
- If you are using Distributed Firewall:
  - Ensure that the Distributed (DFW) firewall is enabled.
  - Ensure that priority 0 is available for the VCF Operations for networks IPFIX profile. If there is another IPFIX profile with priority 0, then you have to change it to some other value.

    > **Note:**
    >
    > From VMware Cloud Foundation 9.0 or higher, if the DFW license is missing or if DFW is deactivated, then Switch IPFIX flows will be the default.
- Verify that DFW is activated on each node of your cluster.

**Note:**

To receive DFW IPFIX flows, you must have an applicable security license enabled. For more information, see the vDefend documentation.

To enable NSX-T IPFIX in VCF Operations for networks:

Select **Enable IPFIX** when adding or editing an NSX-T Manager data source.

After you enable IPFIX, VCF Operations for networks creates its own Operations for Networks Collector profile and Operations for Networks IPFIX profile on NSX-T. Ensure that you do not modify any of these profiles.

After enabling IPFIX on NSX-T, if the flows are not seen in VCF Operations for networks, then the following events may occur:

- Operations for Networks Collector Profile is not registered in the NSX-T Manager.
- Operations for Networks IPFIX Profile is not registered in the NSX-T Manager.
- Operations for Networks IPFIX Profile port number has changed.
- Operations for Networks Collector Profile does not match in the Operations for Networks IPFIX profile in the NSX-T Manager.

  **Note:**
  To resolve all the above issues, enable NSX-T IPFIX again.
- Operations for Networks IPFIX Profile priority is not zero in the NSX-T Manager.
  To resolve this issue, log into NSX-T Manager and set the priority of Operations for Networks IPFIX Profile to zero.
- Operations for Networks Collector IP cannot be added in existing Operations for Networks Collector Profile in the NSX-T Manager.
  Delete one of the collectors from the Operations for Networks Collector Profile in the NSX-T Manager and re-enable NSX-T IPFIX from data source page.
- If you are using Distributed Firewall, then check if Distributed Firewall is deactivated in NSX-T Manage.
  Log into NSX-T Manager and enable the DFW firewall.

## Flow Support for Physical Servers

VCF Operations for networks supports the device that sends the NetFlow data of versions v5, v7, and v9. If the DNS Mapping and Subnet-VLAN mapping information is provided, VCF Operations for networks can enrich the NetFlow data with DNS Domains, DNS Host Names, Subnets, and Layer 2 networks. This feature is available for the Enterprise License users only.

To configure NetFlow in VCF Operations for networks, perform the following steps:

1. Add a Physical Flow Collector for NetFlow and sFlow.
2. Configure the NetFlow collector in the physical devices to receive the flows.
3. Importing the DNS Mapping.
4. Configuring the Physical Subnets and VLANs.

### Configure a NetFlow Collector in a Physical Device

In VCF Operations for networks, you can configure physical devices manually to send the NetFlow information to the VCF Operations for networks NetFlow collector.

To configure most of the physical devices, perform the following steps:

1. Create a flow record.
   The required fields for a flow record are:
   - Mark the following fields as `Match`.
     - `ipv4 protocol`
     - `ipv4 source address`
     - `ipv4 destination address`

  - transport source-port
  - transport destination-port
  - interface input
- Mark the following fields as `Collect`.
  - direction
  - counter bytes
  - counter packets
  - timestamp sys-uptime first
  - timestamp sys-uptime last
- Mark the following field as `Match` or `Collect`. If not, skip it.
  - transport tcp flags

2. Create a flow exporter.
   - Provide VCF Operations for networks NetFlow collector IP and port 2055.
3. Configure the flow cache as follows:
   - Active timeout: 30 seconds
   - Inactive timeout: 60 seconds
4. Create the flow monitor using the created flow record and flow exporter.
5. Configure the monitor on each interface.

The sample steps to configure the physical devices are provided in the following sections:

- Configuring a Netflow Collector for Cisco 4500 Series Switches
- Configuring a Netflow Collector for Cisco Nexus 1000v Switches
- Configuring a Netflow Collector for Cisco Nexus 9000 Series Switches

**Note:**
The steps may vary from version to version and device to device.

**Configuring a Netflow Collector for Cisco 4500 Series Switches**
In VCF Operations for networks, you can configure a netflow collector for Cisco 4500 series switches.

1. To create the flow record

```
configure terminal
flow record netflow-original
match ipv4 protocol
match ipv4 source address
match ipv4 destination address
match transport source-port
match transport destination-port
match interface input
collect transport tcp flags
collect counter bytes
collect counter packets
collect timestamp sys-uptime first
collect timestamp sys-uptime last
End
```

2. To create the flow exporter

```
configure terminal
flow exporter e1
destination <PROXY_IP>
transport udp 2055
end
```

3. To create the flow monitor

```
configure terminal
```

```
flow monitor m1
record netflow-original
exporter e1
end
```

4. To configure the timeouts

```
configure terminal
cache timeout inactive 30
cache timeout active 60
end
```

5. To configure the flow monitor for each interface on the ingress mode and the egress mode or at least the ingress mode

```
configure terminal
interface <INTERFACE_NAME>
ip flow monitor m1 unicast input
end
```

**Configuring a Netflow Collector for Cisco Nexus 1000v Switches**

In VCF Operations for networks, you can configure a netflow collector for Cisco Nexus 1000v switches.

1. To configure timeouts

```
configure terminal
Active timeout 60
Inactive timeout 15
end
```

2. To configure the exporter

```
configure terminal
flow exporter <EXPORTER_NAME>
destination <PROXY_IP>
transport udp 2055
source <VSM_IP_OR_SUBNET>
end
```

3. To configure the flow monitor for each interface:

```
configure terminal
flow monitor <MONITOR_NAME>
record netflow-original
exporter <EXPORTER_NAME>
end
```

4. To configure the flow monitor for each interface on the ingress mode and the egress mode or at least the ingress mode.

```
configure terminal
port-profile type vethernet <IF_NAME>
ip flow monitor <MONITOR_NAME> input
ip flow monitor <MONITOR_NAME> output
.
.
end
```

**Configuring a Netflow Collector for Cisco Nexus 9000 Series Switches**

In VCF Operations for networks, you can configure a netflow collector for Cisco 9000 series switches.

Here are some of the sample device commands for Cisco Nexus 9000:

1. To enable the NetFlow feature

```
configure terminal
```

```
feature netflow
end
```

2. To create flow record

```
configure terminal
flow record vrni-record
match ipv4 protocol
match ipv4 source address
match ipv4 destination address
match transport source-port
match transport destination-port
match interface input
collect transport tcp flags
collect counter bytes
collect counter packets
collect timestamp sys-uptime first
collect timestamp sys-uptime last
End
```

3. To create flow exporter

```
configure terminal
flow exporter vrni-exporter
destination <PROXY_IP>
transport udp 2055
version 9
source <INTERFACE_NAME>
end
```

4. To create the flow monitor for each interface

```
configure terminal
flow monitor vrni-monitor
record vrni-record
exporter vrni-exporter
end
```

5. To configure timeouts

```
configure terminal
cache timeout inactive 30
cache timeout active 60
end
```

6. To configure the flow monitor for each interface on the ingress mode and the egress mode or at least the ingress mode

```
configure terminal
interface <INTERFACE_NAME>
ip flow monitor vrni-monitor input
end
```

## Enriching Flows and IP Endpoints

You can import the DNS mapping and the subnet-VLAN mapping information through the UI.

The flow information is enriched with the following types of information based on the import of the DNS data and the specification of subnet-VLAN mappings.

- Source DNS Domain
- Source DNS Host Name
- Destination DNS Domain

- Destination DNS Host Name
- Source L2 Network
- Source Subnet network
- Destination L2 Network
- Destination Subnet network

The IP Endpoint information is enriched with the following types of information based on the import of the DNS data and the specification of subnet-VLAN mappings.

- DNS Domain
- DNS Host Name
- FQDN
- L2 Network
- Subnet network

For more information on enriching flows through the DNS information, refer Import the DNS mapping file.

For more information on enriching flows through the Subnet-VLAN mapping, refer Configure Mapping Between Subnet and a VLAN.

**Note:**

- The DNS mapping and subnet information are enhanced only for the physical IPs. No subnet or DNS mapping information is associated with any vNIC.
- The information is enriched only for flows that have been seen by VCF Operations for networks after this information has been imported.

### Searching Physical to Physical Flows

You can search for the physical to physical flows based on the following attributes:

- Source DNS Host
- Destination DNS Host
- Source DNS Domain
- Destination DNS Domain
- Source Subnet Network
- Destination Subnet Network

You can search for Physical-Physical flows based on the following attributes. A few examples of flow search query using the enriched DNS and Subnet-VLAN mapping information are as follows:

```
bytes,Dns Domain,Dns Host,l2 network of flows where flow type = 'Physical-Physical'
```

```
bytes,Dns Domain,Dns Host,l2 network of flows where flow type = 'Source is VM' and flow type = 'Destination is Physical'
```

```
bytes,Dns Domain,Dns Host,l2 network of flows where flow type = 'Source is Internet' and flow type = 'Destination is Physical'
```

## Viewing Blocked and Protected Flows

The NSX-IPFIX integration enables the visibility of the blocked and protected flows in the system.

The basic filters in the **Security Planning** page are as follows:

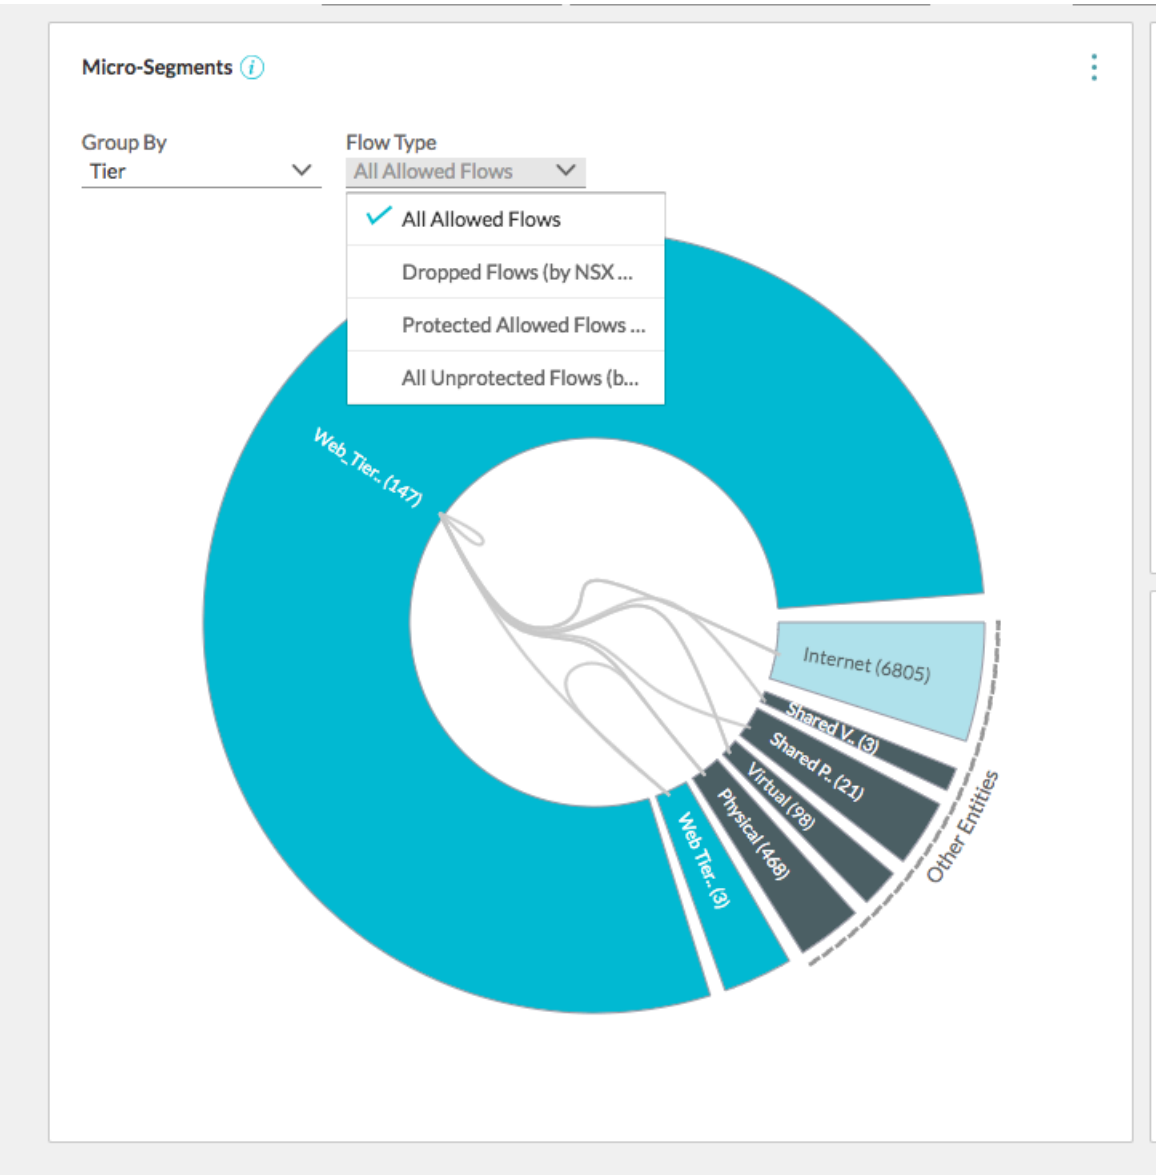
- **All allowed flows**: To see all the flows where firewall rules are set as **Allowed**, select this option. The **All allowed flows** option is the default option.
- **Dropped flows**: This option helps to detect the dropped flows and planning the security in a better way.
- **Protected allowed flows**: This option helps to detect all the flows which have a rule other than of the type `any(source)any(dest)any(service)allow` associated with it. Such flows are known as protected flows.

- **All unprotected flows**: This option helps to detect all the flows that have the default rules of the type `any(source)any(dest)any(service)allow`. Such flows are known as unprotected flows.

The firewall rules are visible only for the allowed and unprotected flows.

For example, if you are in the planning phase and you want to see the allowed flows in the system, perform the following steps:

1. On the Micro-Segmentation Planning page, for a particular group, select **All Allowed Flows** from the drop-down menu.
2. Click the dropped flows in the topology diagram to see the corresponding recommended firewall rules.
3. Implement those firewall rules by exporting them into the NSX manager.



## Network Address Translation (NAT)

VCF Operations for networks supports Static NAT (SNAT), Dynamic NAT (DNAT), reflexive rules in the flows, and the VM-VM Path for NSX-T Edges, Fortinet, and Check Point.

The NAT flow support in VCF Operations for networks is as follows:

- VCF Operations for networks supports the nested NAT hierarchy for NSX for vSphere and NSX-T, and for physical devices, VCF Operations for networks supports the single hierarchy (DNAT) for Fortinet only.

- VCF Operations for networks supports the edges and the tier routers with NAT-defined uplinks.

  **Note:**
  The NAT rules on the NSX Edge version 5.5 or the previous versions are not supported.
- VCF Operations for networks supports SNAT rules with range. However, DNAT must be one-to-one mapping between the destination and translated IP addresses (Parity with NSX for vSphere).
- For Check Point, NAT rules both auto or manually generated are supported for both the source and the destination as network, network-group, or address-range.

**Queries**

To view NAT rules, use the following queries:

- To view all the NAT rules in NSX-T, use the `NSX-T Edge NAT Rule` query.
- To view all the NAT rules in Fortinet, use the `Fortinet NAT Rule` query.
- To view all the NAT rules in Check Point, use the `Check Point NAT Rule` query.
- To view all the NAT rules, use the `NAT Rule` query.

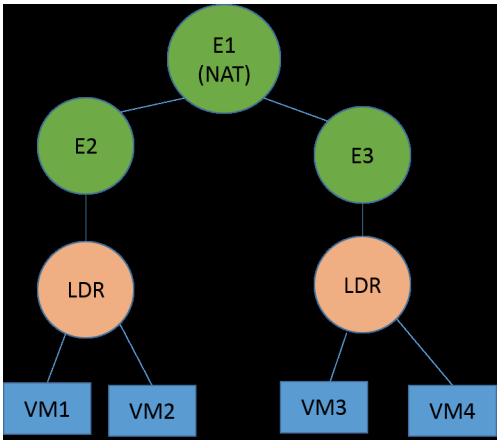
**Consideration**

- VCF Operations for networks does not support the following use cases:
  - In NSX-T, NAT rules can be applied at the service level. For example, in NSX-T, L4 ports set is a type of service and the associated protocols can be TCP or UDP. So in the VM-VM path, the service level details are not supported.
  - Any port level translation is not supported.
  - The SNAT match destination address and the DNAT match source address are not supported. Use the SNAT match destination address as the destination IP address when you specify the SNAT rule. Use the DNAT match source address as the source IP address when you specify the DNAT rule. For example, if there is a destination IP address mentioned in the SNAT rule, VCF Operations for networks applies the SNAT rule irrespective of whether the packet has the destination address as the destination IP address.
  - NSX-T Edge firewall has implications for the data path when enabled with the NAT service on the same logical router. If a flow matches both NAT and Edge firewall, the NAT lookup result takes precedence over firewall. So the firewall is not applied to that flow. If the flow matches only a firewall rule, then the firewall lookup result is honored for that flow.
  - Service translation is not supported.
  - vSEC NAT is not supported.

## NAT Flow Support - Examples

This section consists of a few examples for the supported NAT flow in VCF Operations for networks.

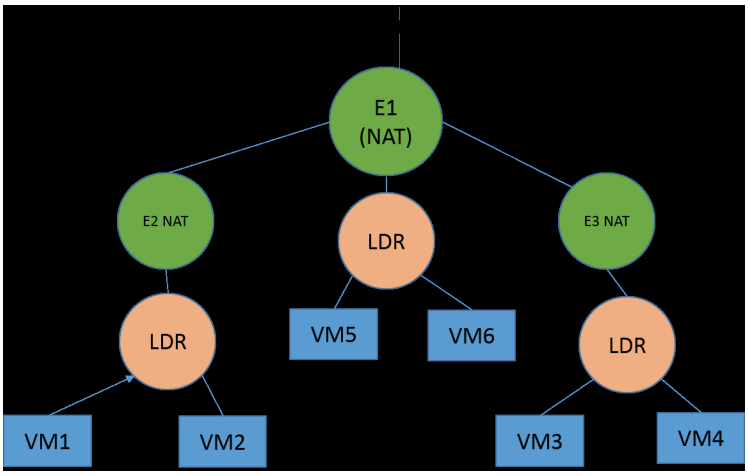
**Example 1**



In this topology, E2, E3, LDRs, VMs (VM1, VM2, VM3, VM4) are part of the NAT domain E1. Anything above E1 such as uplink of E1 is part of the default NAT domain. This topology consists of the following:

The flow from VM1 to VM2 and VM2 to VM1 is reported in VCF Operations for networks. Similarly the flow from VM3 to VM4 and VM4 to VM3 is reported.

**Example 2**



This topology consists of the following:

- VM1 and VM2 are part of the E2 domain.
- VM3 and VM4 are part of the E2 domain.
- The E2 NAT domain and the E3 NAT domain are child domains of the E1 NAT domain.
- E1 is the single child of the default NAT domain.
- VM5 and VM6 are part of the E1 NAT domain.

From example 2, the following flows are reported in VCF Operations for networks:

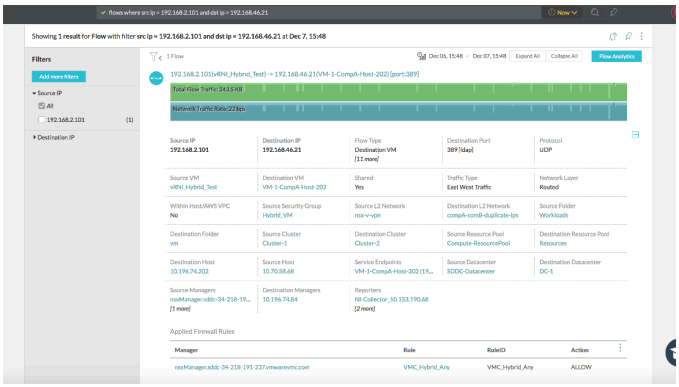
- Flow from VM5 to VM6
- Flow from (VM1, VM2) to (VM3, VM4).

## VMware Cloud on AWS Flows

If you have enabled IPFIX on the data source in the **Settings** page, you can view the flow count and the last collection time.

You can search for any particular flow and get the details associated with the entities. For example, you can view the policy segment and the policy group information in `Source L2 Network` and `Source Security Group` respectively. You can also view the policy firewall rule attached to flow.

VCF Operations for networks supports the hybrid flows over the VPN. The flow information is enriched with the source and the destination entities.



**Note:**
If you have upgraded VMware Cloud on AWS from 1.8 to 1.9 version, you might see the flows twice on the UI.

## Create AWS VPC Flow Log

With Virtual Private Cloud (VPC) Flow Logs, you can capture information about the IP traffic going to and from network interfaces in your VPC.

You can create flow logs through the AWS portal.

1. Sign in to the AWS console.
2. In the **Find Service**text box, enter and select `CloudWatch`.
3. Go to **Logs** > **Action** > **Create log group**.
   The **Create log group** window appears.
4. In the **Create Group Name** field, enter a group name and click **Create log group**.

   **Note:**
   You should set the **Retention setting** to **1 day**. VCF Operations for networks does not retrieve data older than one day, and setting the retention to 1 day, saves on AWS expenses.
5. In the left navigation pane, click **Service** and then enter and select `VPC`.
6. In the **VPC Dashboard** page, click **Your VPCs**.
7. Select the VPC that you want to modify, and click **Flow Logs** > **Create flow log**.
8. In the **Create flow log** window, configure the flow log:

| Option | Action |
|---|---|
| **Filter** | Select one of the following: **Accept**, **Reject**, or **All**. |
| **Destination** | Select **Send to CloudWatch Logs**. |
| **Destination log group** | Select the log group you created. |

9. Click **Set Up Permissions**.
   The system opens the **VPC Flow Logs is requesting permission to use resources in your account** page.
10. Create an IAM role.
    a) In the **VPC Flow Logs is requesting permission to use resources in your account** page, in the **IAM Role**, select **Create a new IAM Role**.
    b) In the **Role Name** text box, enter a role name.
    a) Click **Allow**.
11. On the **Create flow log** page, in the **IAM role** drop-down, select the role you created.
12. Click **Create**

Flow log starts publishing on the selected log group. For more information about VPC Flow Log, see the AWS documentation at https://docs.aws.amazon.com/vpc/latest/userguide/flow-logs.html#create-flow-log.

## Sending Flow Records from F5 To VCF Operations for networks Collectors

To send the flow records, you must do the following:

| Sl No. | Task | Link |
|---|---|---|
| 1 | Create a pool of IPFIX collectors to receive the IPFIX log messages from the BIG-IP system. | Create a pool of IPFIX Collectors |
| 2 | Create a log destination to format the logs in IPFIX templates. | Create an IPFIX Log Destination |
| 3 | Create a log publisher to send logs to a specified log destinations. | Create a Log Publisher |
| 4 | Create an iRule to send the flow information to the configured VCF Operations for networks collector. | Create iRules |
| 5 | Add the iRule to a virtual server configuration so that the iRule parses all of the virtual server's network traffic. | Add the iRule To a Virtual Server |
| 6 | If the collector VM is unreachable from F5, you must create a route entry for the collector to send the flow records. | Create a Route Entry |

## Create a pool of IPFIX Collectors

The BIG-IP system sends IPFIX log messages to a pool of IPFIX collectors.

1. Log in to the F5 console.
2. Click **Main** > **Local Traffic** > **Pools** > **Pool Lists** > **Create**.
   The **New Pool** screen opens.
3. In the **Name** text box, enter a unique name for the pool.
4. In **Health Monitors** section, select **gateway_icmp** and move it in the **Active** box.
5. In the **New Member** section, configure the collector IP address and click **Add**.

| Option | Action |
|---|---|
| **Node Name** | Enter the Collector IP address. |
| **Service Port** | 2055 |

6. Click **Finished**.

## Create an IPFIX Log Destination

Create a log destination to format the logs in IPFIX templates. After the formatting, these logs are sent to the IPFIX collector.

1. In the F5 console, click **Main** > **System** > **Logs** > **Configuration** > **Log Destinations** > **Create**.
   The **Log Destinations** screen appears.
2. In the **Name** text box, enter a unique name.
3. In the **Type** list, click **IPFIX**.
4. Configure the **IPFIX Settings**.

| Option | Action |
|---|---|
| **Protocol** | Click **Netflow V9**. |
| **Pool Name** | Click the pool name you created in the previous step. |

5. Click **Finished**.

### Create a Log Publisher

To send the logs to a specified log destination, you need to create a log publisher .

1. In the F5 console, click **Main** > **System** > **Logs** > **Configuration** > **Log Publishers** > **Create**.
   The **Log Publishers** screen appears.
2. In the **Name** field, enter a unique name.
3. In the **Destination** box, select the log destination you created previously from the **Available** box, and move it in the **Selected** box.
4. Click **Finished**.

### Create iRules

To send the flow information to the configured VCF Operations for networks collector, you must create two iRules. One iRule for the TCP protocol and another iRule for the UDP protocol.

1. In the F5 console, click **Main** > **Local Traffic** > **iRules** > **iRule List** > **Create**.

   Local Traffic

   The **New iRule** screen appears.
2. In the **Name** text box, enter a unique name.
3. In the **Definition** text box, enter the TCP rules for the TCP protocol and the UDP rule for the UDP protocol. For information on the rules, see iRules for the TCP and UDP Protocols.
   Ensure the iRule points to the publisher created previously.
4. Click **Finished**.

#### iRules for the TCP and UDP Protocols

**TCP Rule**

Use the following rule to create the iRule for TCP protocol:

> **Note:**
> Ensure the iRule points to the Log Publisher created previously.

```
when RULE_INIT {
  set static::http_rule1_dest ""
  set static::http_rule1_tmplt ""
}

# CLIENT_ACCEPTED event to initiate IPFIX destination and template
when CLIENT_ACCEPTED {
  set start [clock clicks -milliseconds]
  if { $static::http_rule1_dest == ""} {
    # open the logging destination if it has not been opened yet
    set static::http_rule1_dest [IPFIX::destination open -publisher /Common/<Log Publisher>]
  }
  if { $static::http_rule1_tmplt == ""} {
    # if the template has not been created yet, create the template
    set static::http_rule1_tmplt [IPFIX::template create "flowStartMilliseconds \
                                                          sourceIPv4Address \
                                                          sourceIPv6Address  \
                                                          destinationIPv4Address \
                                                          destinationIPv6Address  \
```

```
                                                    sourceTransportPort \
                                                    destinationTransportPort \
                                                    protocolIdentifier \
                                                    octetTotalCount \
                                                    packetTotalCount \
                                                    octetDeltaCount \
                                                    packetDeltaCount \
                                                    postNATSourceIPv4Address \

## UDP Rule

Use the following rule to create the iRule for UDP protocol:

> **Note:**
> Ensure the iRule points to the Log Publisher created previously.

```
when RULE_INIT {
  set static::http_rule1_dest ""
  set static::http_rule1_tmplt ""
}

# CLIENT_ACCEPTED event to initiate IPFIX destination and template
when CLIENT_ACCEPTED {
  set start [clock clicks -milliseconds]
  if { $static::http_rule1_dest == ""} {
    # open the logging destination if it has not been opened yet
    set static::http_rule1_dest [IPFIX::destination open -publisher /Common/<Log Publisher>]
  }
  if { $static::http_rule1_tmplt == ""} {
    # if the template has not been created yet, create the template
    set static::http_rule1_tmplt [IPFIX::template create "flowStartMilliseconds \
```

```
                                                    sourceIPv4Address \
                                                    sourceIPv6Address  \
                                                    destinationIPv4Address \
                                                    destinationIPv6Address  \
                                                    sourceTransportPort \
                                                    destinationTransportPort \
                                                    protocolIdentifier \
                                                    octetTotalCount \
                                                    packetTotalCount \

    # send the IPFIX log
    IPFIX::destination send $static::http_rule1_dest $rule1_msg1
}
```

## Add the iRule To a Virtual Server

1. In the F5 console, click **Main** > **Local Traffic** > **Virtual Server** > **Virtual Server List**.
   The **Virtual Server List** screen appears.

2. Select the server you want to add the iRule.
3. Click **Resources** tab, and in the iRule section click **Manage**.
4. Select the TCP and UDP iRules that you created previously and move the iRules from **Available** box to **Enable** box.
5. Click **Finished**.

### Create a Route Entry

The collector VM must be reachable from F5. If the collector VM is unreachable from F5, you must create a route entry for the collector.

To check if the collector VM is reachable from F5, you must run the following command: `ping <collector-ip> -I <virtual interface>` from the Command Line Interface (CLI). If the collector is unreachable form F5, you must create a route entry for the collector.

For example,

```
admin@(localhost)(cfg-sync Standalone)(Active)(/Common)(tmos)# ping 10.153.191.116 -I VLAN301
PING 10.153.191.116 (10.153.191.116) from 10.115.30.50 VLAN301: 56(84) bytes of data.
From 10.115.30.50 icmp_seq=1 Destination Host Unreachable
From 10.115.30.50 icmp_seq=2 Destination Host Unreachable
```

1. In the F5 console, click **Main** > **Network** > **Routes** > **Add**.
   The **New Route** screen appears.
2. In the **Properties** section, configure the route entries to send the flow records from F5 to the VCF Operations for networks collector through the virtual server.

## Viewing Kubernetes and Tanzu Kubernetes Grid Integrated Edition Scoping and Flow Information

You can perform scoping of container entities and view the flow information in VCF Operations for networks.

#### Tanzu Kubernetes Grid Integrated Edition and Kubernetes Flow Information

VCF Operations for networks supports the following flow types for Kubernetes entities.

- VM to Kubernetes Pod
- Kubernetes Pod to Pod
- Destination is Kubernetes Pod
- Source is Kubernetes Pod

You can use these flow types to search for a particular Kubernetes entities.

For example, `flows where flow type = x` where *x* is one of the flow types

VCF Operations for networks can provide flow information such as metrics, time-series and relations for all entities, which includes the container source and destination details and its entities details.

Also, you can view the top talkers by Kubernetes Cluster, Namespace, Service and Node on the Flow Analytics Dashboard.

#### Planning and Micro-segmentation of Kubernetes Entities

You can plan for a specific Kubernetes entity type by selecting Kubernetes Cluster, Kubernetes Service, Kubernetes Namespace, or Kubernetes Node as the scope and Micro-Segments in the Plan Security page. Also, you can plan or analyze data for the application and define grouping based on Kubernetes entities to view the application flow information.

Also, you can export the recommended firewall rules related to Kubernetes entities in the YAML format from Micro-Segments in the Plan Security page.

**Note:**
You cannot export the application scope in the YAML format if it contains VMs or VM members. If the application contains only container entities, exporting to YAML format is available.

# Working with Guided Network Troubleshooting

In VCF Operations for networks, you can use Guided Network Troubleshooting to troubleshoot supported entities from a single page. VCF Operations for networks creates a dependency graph for the entity you want to troubleshoot and shows you possible anomalies that can influence performance and functionality.

In the Guided Network Troubleshooting, when you select an entity to troubleshoot, VCF Operations for networks creates a dependency graph with all other related entities, shows all the relevant and correlated metrics and alerts of the entities in the dependency graph, and highlights all the possible anomalies in the dependency graph and the correlated metrics.

**Note:**
For each tenant, VCF Operations for networks supports a maximum of 5,000 troubleshooting incidents. Also, you can only view dependency graph for a time range within the last 30 days.

## Start a New Troubleshooting Incident

To find the root cause of an abnormality or issue, you can start a troubleshooting incident when you see any abnormality or problems against an entity in VCF Operations for networks. Troubleshooting incidents are also useful to visualize or analyze the dependencies for any entity.

**Note:**
You can also lunch a troubleshooting incident from Ensemble. From Ensemble, click **Troubleshoot** button for the entity you want to start a troubleshooting incident. Ensemble is specifically designed to discover, curate, and manage applications. For more information, see the *Using and Managing VMware Ensemble*.

1. From the left navigation pane, select **Troubleshoot** > **Start New Incident**.
   You see the **Start Troubleshooting** window.
2. From the **Scope** drop-down menu, select the entity you want to troubleshoot.
3. From the **Time Range** drop-down menu, select a **Preset** time range or set a **Custom** time range.
4. In the **Incident Name** text box, enter a name for the incident..
   Based on your scope selection, the system automatically generates an incident name. But you can change or update the automatically generated incident name as per your requirement.
5. Click **Start New**.
   When you select a scope, you see the last 20 incidents that were most recently modified and related to your selected scope at the bottom of the window.
6. Optional: To open an in-progress incident, click the incident you want to view.

A new **Troubleshoot** tab opens on your browser.

## Viewing Troubleshooting Incident Page

The **Troubleshoot** page provides all the relevant and required information you might need to troubleshoot an entity using Guided Network Troubleshooting in VCF Operations for networks.

On this page, you see the following sections:

| Section | Details |
|---|---|
| **Troubleshooting Insights** | You see:<br>• List of the top three troubleshooting insights which contain troubleshooting hints.<br>You can click the **Analysis** button to view the anomaly details. |
| **Troubleshooting Information** | You see:<br>• Information related to the incident, such as status, root cause metrics, closing remarks, created by, created at, and so on.<br>• Information related to the entity that you are troubleshooting, such as start entity name, traffic and flows on the entity.<br>• Any past incidents created for the entity. |
| **Relationships** | You see the dependency graph of the selected entity for which you are troubleshooting.<br>The dependency graph shows all the related entities based on network, storage, and compute relations. You can select the entities in the dependency graph, and view information related to each selected entity.<br>In the dependency graph, all the related entities are grouped in various categories, such as by VMs, Host, Flows, and so on.<br>You can click the plus icon to expand a group. You can also use sort by and group by function to see entities in a particular order in a group.<br>The system highlights the path and entities identified with the anomalies in red. |
| **Metrics** and **Alerts** | You see all the metrics and alerts relevant to the entity you have selected in the **Relationship** widget.<br>You see all the anomalies in a metrics highlighted by<br>( )<br>for quick detection.<br>You can view report based on the analysis type you have selected. Also, you can filter metrics and alerts based on various parameters, such as metric name, entity name, and so on.<br>If you find a metric that might be a potential root cause, you can click to mark the metric.<br>If you find a metric which you want to mark for your reference, you can click to flag the metric. |
| **Notes** | You see a section for notes to add your findings, insights, or other information that you want to remember.<br>You can use this section to collaborate with other users, as anyone who opens the troubleshooting session can see your notes. |

You can also modify the scope of the analysis by using **Modify** button. When you click the **Modify** button located at the top-right corner, you see **Troubleshooting Scope** widget.

| | |
|---|---|
| **Troubleshooting Scope** | In the **Troubleshooting Scope**, you see the following:<br>• You see the selected time range for troubleshooting.<br>You can also change the selected time range for which you want the system to perform troubleshooting.<br>• You see the selected analysis type and level.<br>The single metric performs troubleshooting on the single metric time-series, and the multi-metrics perform troubleshooting on two correlated time-series metrics.<br>• You can also see the sensitivity level. The sensitivity level determines how the system detects anomalies. The higher the level you select, the more the number of anomalies you see.<br>You can select one of the following sensitivity level: low, medium, or high. |

## Find Root Cause by Using Troubleshooting Incident

You can start a troubleshooting incident to find a root cause for any abnormality or problem that you have observed on an entity in VCF Operations for networks.

To find root causes in the **Troubleshoot** page, you can do the following steps.

- In the **Troubleshooting Insights** widget, view the list of top three troubleshooting insights which contain troubleshooting hints.
  - Click the **Analysis** button to view insight which includes metric details and potential anomalies.
- In the **Relationship** widget, select the related entities marked in red to view metrics details related to that entity to find potential anomalies or root cause.
  - You can drill down all the related entities that are marked as red, one by one, and view metrics reated to the entity to find the problem you are facing in your environment. Click (+) to expand each entity group.

    If required, you can also click other entities in the relationship graph and view the related metrics for your troubleshooting investigation.
- In the metric, you can click **Analysis** to view correlated metric analysis.
  - While investigating the root cause you can use filter to find specific metrics and alerts of your interest. All the anomalies in a metrics highlighted by ( ).

    You can also flag a metric and mark a metric as root cause.
- Use the Notes sections to add your thoughts and observations. Anyone who opens this session can see your notes.
- When your investigation is complete, you can close the session by clicking **Close Session** button.

  You can close a session as resolved or unresolved. Resolved status implies you have found a root cause and unresolved status implies that you did not find any root cause. You can also add remarks while closing a session to note down any comments.

  **Note:**
  You can work on a closed incident irrespective of the resolution. You can also change the status to resolved or unresolved. But, you cannot reopen a closed incident.

## Managing Incidents

On the **Troubleshooting Incidents** page, you can manage all the available incidents, start a new incident, and view a summary of all the existing incidents.

In the **Troubleshooting Incidents** page, you see the following sections:

| Section | Details |
|---|---|
| **Summary** | You see:<br>• A summary of all the incidents, including status, entity count for in-progress incidents, and count of top root causes. |
| **Incidents** | You see:<br>• A list of all the incidents, their status, and other important information.<br>You can edit, share, or delete any incidents using the corresponding **Edit**, **Share**, and **Delete** button available in the action column.<br>**Note:**<br>Only admin users can delete incidents created by other users. Member users can delete only the incidents that they create. Audit users cannot delete or create any incidents. |

In this page, you can also create a new incident using **Start New** button.

# Entities

## Viewing Entity Details

The entity pages provide a comprehensive outlook of entities that are present in your data center. This information can range from detailed topologies to show relationships with other entities of your data center to detailed metrics about an entity.

Think of your entire data center as being composed of entities and their relationships. For example, a virtual machine is an entity, and the virtual machine is part of a host which is another entity. Here, the virtual machine and the host share a relationship with each other. VCF Operations for networks provides visibility and information of such entities and relationships, and numerous other entities and relationships that are part of your data center.

Each entity on VCF Operations for networks has a dedicated entity page. This page is a collection of widgets and each widget shows specific information related to the entity. The information provided is both real time and historical, and an exhaustive list of metrics and properties for the entity.

You can expand the **Entities** option on the left navigation panel to view all the entities on VCF Operations for networks. If you want to see more information about entities, then click **Profile** > **Help** on the top-right corner of the page.

### Time Range Widget

The time range widget enables you to view the state of the entity at a particular time in the past. It also provides a bird's eye view of alerts that were detected across a selected time range.

To access the time range widget, click

next to the entity name on top of the page, and select the time range that you want to view.

## Viewing VCF Operations for networks System (NI System) Details

The VCF Operations for networks System (NI System) page provides a snapshot of all the information related to the system. To access the VCF Operations for networks System page:

- On the **Infrastructure and Support** page, click **View Details** next to **Overview**. The NI System page appears.
- Provide `NI System` as the search query to view the VCF Operations for networks System page.

The NI System page is divided into three sections:

- Overview: This section consists of information on the key properties, the data sources, the problems that are open, and all the changes and the problems related to the system. View the details of each data source by clicking it.
- Alerts: This section lists all the problems and changes in the system, data sources, platforms, and the collectors.
- Platforms and Collectors: This section lists all the platforms and the collectors associated with the system. To view more details about any platform or collector, click it.

## Viewing Platform VM details

The **Platform VM** page provides a snapshot of the properties, changes, and problems of a particular platform node.

In the **Platform VM** page, you see:

- Important information about the selected platform node, such as name, IP address, CPU cores, memory, the last upgraded time, and the version.
- Open problems that are associated with the platforms and are open.
- The list of alerts related to the selected platform node.
- The graphical representation of the metrics such as CPU Usage, Memory Usage, and Data Disk Usage.

## Viewing Collector VM Details

The **Collector VM** page provides a snapshot of the properties, changes, and problems of a particular collector node.

In the **Collector VM** page, you see:

- Important information about the selected platform node, such as name, IP address, CPU cores, memory, the last upgraded time, and the version.
- Number of open problems related to the collector and the problem details.
- Number of open problems related to the data sources and the problem details.
- List of the changes that occurred in the data source in the last seven days.
- Details of the data sources and the NetFlow reporters available in the collector. The number of flows are shown for each NetFlow reporter. For data sources, the number of flows and the discovered VMs are shown.
- The graphical representation of the metrics such as CPU Usage, Memory Usage, and Data Disk Usage

## Viewing the VMware vCenter Manager Assessment Dashboard

The **VMware vCenter Manager** page provides a snapshot of all the VMs, VLANs, hosts connected to the **VMware vCenter Manager**, total numbers of traffic, and East-West traffic. You also see various metrics/widgets such as Top talking VMs, Network Optimization with NSX, Path Optimization with NSX, Application Centric Networking with NSX, and Crown Jewel Analysis.

### Generate NSX Assessment Report

You can get a network assessment and optimization report if you do not have NSX Manager added as a data source in VCF Operations for networks.

1. Open a VMware vCenter Manager dashboard.
2. On the top-right corner, click **Generate Report**.
   Open the generated PDF which contains the network assessment and optimization report.

### Application Troubleshooting Use Case

In VCF Operations for networks, you can get an end to end visibility of your applications, where you create applications, set threshold metrics, view flows in and out of applications, view detailed physical path, and even troubleshoot any problem or incident.

After you have added all your data sources, let's explore how you can manage and troubleshoot your application in more details:

| Goal | Description | Actions |
|---|---|---|
| Create Application | After you add your data sources, you can either discover your application or create/ define applications. | • To learn how to create an application, see Create an Application Manually<br>• To discover existing application, see Discover Applications. |
| Add threshold analytic to monitor application performance | To know when the network performance of an application drops below certain threshold, you can add threshold limit to your applications.<br>For example, you can set a threshold for round-trip time (RTT) in your application. Whenever, the RTT cross the threshold, you get an alert. | To learn how to configure thresholds, see Configure Thresholds and Alerts. |
| Search for flows to view network routing and flows details | When you get a threshold violation alerts, you can search for the flows to understand more details about the flow and to track the network path. | To learn about search queries, see Working with Search Queries. |
| See VM-VM path | When you search for flow and click on the flows that you like to view, a dashboards opens. You can view VM-VM path and VM underlay path to understand the flow better. | To learn about VM-VM path, see Network Visibility. |
| Open Network Map | To see the detailed physical path, you can go to the Network Map page and use the path search option.<br>The path details give you an idea of what components in the path need further investigation. | To learn about the Network Map and path search, see Working with the Network Map. |
| Troubleshoot an incident | After you have an idea what could be the problem, you can open a troubleshooting incident which will guide you to further investigate and find the route cause of your problem. | To learn about troubleshooting incident, see Working with Guided Network Troubleshooting |

**Latency Troubleshooting Use Case**

In VCF Operations for networks, you can get visibility into the latency, set a threshold to get notified when the latency violates the configured threshold limits, and identify the root cause of the high latency.

In VCF Operations for networks, you can get details about the following latency-related metrics:

| Types | Descriptions | Access the latency metrics |
|---|---|---|
| **vNIC to vNIC latency** | **The time taken by the packet to travel from the source VM's vNIC to the destination VM's vNIC on the same ESX host or across ESX hosts.** | **See Latency Metrics.**<br>**To monitor these metrics, you can do the following:**<br>**- Create a custom dashboard to monitor these metrics**<br>**- Set a threshold limit to get alert when there is a threshold violation.**<br>**- Create search-based alert for the metrics that are not supported in threshold metrics.** |
| **vNIC to PNIC and PNIC to vNIC latency** | **The time taken by the packet to travel from the source VM's vNIC to the PNIC of the host transport node of the source VM.** | |
| **PNIC to PNIC latency (VTEP to VTEP latency)** | **The time taken by the packet to travel from the PNIC/VTEP of the host of the source VM to the PNIC/VTEP of the host of the destination VM over the underlay network connecting the two hosts.** | |
| **TCP RTT & Retransmission counts for IPFIX Flows** | **NSX-T DFW IPFIX flow records include additional information about the TCP Round Trip time for establishing the flow and the TCP packet retransmission count to compensate for the high RTT or drops. These are in the form of retr ansmissionCount and averageLatency fields associated with the flow between a pair of IP addresses. vRNI enriches the flow information with VM, Hosts, Applications, E-W/N-S nature of traffic etc. and aggregates them and presents the max and average values for these metrics in association with the flows.** | |

## Troubleshoot Latency

When you gain visibility on the latency metrics, you find the root cause of the problem and solve the latency problem.

Let's explore how you can troubleshoot latency using VCF Operations for networks:

1. Run the following search query to get the top 10 vNIC-vNIC pairs with high latency:
   `netopa.interfacePairLatency.absolute.maximum.microsecond, netopa.interfacePairLatency.absolute.average.microsecond,vm1, vm2, virtualInterface1, virtualInterface2 of interface pair info where host is set and virtualInterface1Type != VMKNIC and netopa.interfacePairLatency.absolute.maximum.microsecond > 0 order by netopa.interfacePairLatency.absolute.maximum.microsecond limit 10`
   The search query lists the top 10 vNIC-vNIC pairs with high latency.
   The overall vNIC-vNIC Latency consists of the following components:
   - Source VM to source PNIC (vNIC - PNIC)
   - Source VTEP to destination VTEP (VTEP - VTEP)
   - Destination PNIC to destination VM (PNIC - vNIC).
2. Identify which of these three components is responsible for the high vNIC-vNIC latency.
   This helps to pinpoint the component responsible and investigate further.
   To determine the latency between the above-mentioned components, we need to run the following queries:
   - Source VM to source PNIC (vNIC - PNIC):
     `netopa.interfacePnicLatency.absolute.maximum.microsecond, netopa.interfacePnicLatency.absolute.average.microsecond, pnic, virtualInterface, vm of interface pnic pair info where host = '<source host name>' and vm = '<source VM name>'`
     or

```
vNIC PNIC Latency, max vNIC PNIC Latency, pnic, virtualInterface, vm of interface
pnic pair info where host = '<source host name>' and vm = '<source VM name>'
```

You get the latency of the first component.

– Source VTEP to destination VTEP (VTEP - VTEP):

```
netopa.interfacePairLatency.absolute.maximum.microsecond,
netopa.interfacePairLatency.absolute.average.microsecond, virtualInterface1,
virtualInterface2, host1, transportNode1, host2, transportNode2 of interface pair
info where virtualInterface1Type = VMKNIC and host1 = '<source host name>'
```

**Tip:**

You get the source host and destination host names by running the initial query to get the vNIC-vNIC latency.

– Destination PNIC to destination VM (PNIC - vNIC):

```
netopa.pnicInterfaceLatency.absolute.maximum.microsecond,
netopa.pnicInterfaceLatency.absolute.average.microsecond, pnic, virtualInterface,
vm of interface pnic pair info where host = '<destination host name>' and vm =
'<destinationvm name>'
```

Or

```
PNIC vNIC Latency, max PNIC vNIC Latency,pnic, virtualInterface, vm of interface pnic
pair info where host = '<destination host name>' and vm = '<destinationvm name>'
```

Based on the result of the above queries you can determine which component is responsible for high vNIC-vNIC latency.

## Viewing VMware vCenter Data Source Details

The **VMware vCenter Data Source** page provides a snapshot of the properties, changes, and problems of a particular data source.

In the **VMware vCenter Data Source** page, you see:

- Important information about the selected VMware vCenter data source, such as IP Address/FQDN, Collector Name, Enabled, number of discovered VMs, IPFIX Enabled Status, and so on.
- All the open problems associated to the data source.
- All the changes and the problems encountered in a particular data source in the last seven days.

## Viewing PCI Compliance Details

The **PCI Compliance** page is available only for the Enterprise License users.

### Access PCI Compliance

1. Go to **Plan & Assess** > **PCI Compliance**.
2. The **PCI Compliance** window appears. Select the required scope, the corresponding entity, and the duration for which you require the data. Click **Assess**.
3. The **PCI Compliance** page appears.

### PCI Compliance page details

The **PCI Compliance** page helps in assessing compliance against the PCI requirements only in the NSX environment. These requirements are mentioned under the first pin in the dashboard. The rest of the pins in the dashboard that provide data for the assessment of these requirements are as follows:

- Network flow diagram: It shows the data flow, firewalls, connections, and other details associated with a network.
- Flows: It lists the flows that you view in the network flow diagram.
- Clear text protocol flows based on the destination port: The traffic that flows on certain ports are in clear text. This pin displays the clear text protocol flows based on a particular destination port.

- Virtual machines in scope: It shows the virtual machines in the scope that you have selected in the query. This pin shows the outgoing rules, incoming rules, and security groups for virtual machines in that scope.
- Security groups of virtual machines: It lists the security groups of the virtual machines.
- Virtual machine count by Security Groups: You can view the list of the virtual machines in a security group by clicking Count in this pin.
- Virtual machine count by Security Tags: You can view the list of virtual machines with security tags by clicking Count in this pin.
- Firewall rules applied on internal traffic : You can view the firewall rules for the traffic between the virtual machines within the selected scope.
- Firewall rules applied on incoming traffic: You can view the firewall rules for the traffic that is coming from a virtual machine outside the scope to the virtual machine within the selected scope.
- Firewall rules applied on outgoing traffic: You can view the firewall rules for the traffic that is going to a virtual machine outside the scope from the virtual machine within the selected scope.
- Security tag membership changes: The changes related to the membership for security tags are shown in this pin.
- Security group membership changes: The changes related to the membership of a security group are shown in this pin.
- Firewall rule changes: The changes related to any firewall rule is listed in this pin.

  **Note:**
  If NSX has nested security groups, then the scope of PCI Compliance should be other than security group.

**Export as PDF**

VCF Operations for networks enables you to create and export the information on the PCI Compliance dashboard as a PDF report.

1. In the PCI Compliance dashboard, click **Export as PDF** on the right top side of the page. The Export to PDF window appears.
2. The Export to PDF window lists all the widgets and their respective properties available on the PCI Compliance dashboard. Select the widgets and the properties that you want to export.

   **Note:**

   - You have to select at least one property.
   - The maximum number of properties that you can select is 20.
   - The maximum number of entries in the list view that can be exported is 100.
   - Certain widgets do not allow you to select the properties. In such instances, specify only the number of entries.
3. Provide a title for the PDF report.

   **Note:**

   - The maximum number of characters in the title is 200.
   - The maximum number of pages that can be generated in the report are 50.
4. Click **Preview**. You can see the preview of the complete report.
5. Click **Export PDF**.

## Viewing Kubernetes Details

You can use the Kubernetes dashboard to get a quick overview of your Kubernetes or Tanzu Kubernetes Grid Integrated Edition deployments in VCF Operations for networks.

You see details about,

- Top talking Clusters and Namespaces based on the flows
- Overview of Kubernetes cluster entities such as, count of Namespaces, Pods, services and Nodes
- Kubernetes clusters added in VCF Operations for networks
- List of containers images running on Pods and count of Pods for each container image

- List of new pods discovered, its count, namespace and cluster details.

In addition, you can click on the count of various Kubernetes entities on the dashboard to the see the list view and go to details of that particular entity.

**Table 1329: Kubernetes Entity Dashboard**

| Dashboard | Description |
|---|---|
| Cluster Dashboard | You get the deployment details at the cluster level, which includes<br>• cluster overview that includes count of namespaces, services, pods and nodes in the deployment.<br>• the list of top namespaces based on flows.<br>• Interaction between namespaces. |
| Namespace Dashboard | You get the cluster namespace details such as,<br>• the namespace overview that includes count of pods, services and nodes that are in that particular namespace.<br>• the list of top talking services based on flows.<br>• Service interactions in the namespace.<br>• Network traffic by packets and bytes. |
| Service Dashboard | You see the details of the Kubernetes services, like<br>• the service overview that includes the count of:<br>— open alerts in 24 hours<br>— incoming & outgoing flows in 24 hours<br>— pods<br>— nodes on which the service is deployed.<br>• connectivity between the kubernetes components and NSX-T.<br>• count of active nodes and pods for a specific period.<br>• service interaction in the namespace.<br>• network traffic by packets and bytes. |
| Pods Dashboard | You see the details such as,<br>• the cluster, namespace, and node that the pod belongs<br>• Network traffic between pods based on packets and bytes |
| Nodes Dashboard | You see details such as,<br>• list of namespaces details<br>• list of services<br>• list of container pods<br>• Network traffic between nodes based on packets and bytes |

**Note:**

- VCF Operations for networks collects Kubernetes cluster details from Tanzu Kubernetes Grid Integrated Edition every 10 minutes.
- VCF Operations for networks collects all objects (Namespace, Node, Pod, Service) from Kubernetes cluster every 4 hours. However, if there is any change in the Kubernetes objects, VCF Operations for networks runs the Watch API and updates the changes immediately.
- Tanzu Kubernetes Grid Integrated Edition does not provide details about the Kubernetes primary nodes.
- VCF Operations for networks provides the details of the clusters that are in successfully created state only.

## Common Alerts or Error Messages

- `Data Source not reachable` - Ping the IP/FQDN of the Tanzu Kubernetes Grid Integrated Edition from the collector virtual machine to ensure Tanzu Kubernetes Grid Integrated Edition is reachable.
- `Kubernetes Cluster API Servers not reachable`-Ensure that all the Kubernetes Cluster API Servers are reachable from the collector virtual machine.

## Viewing Load Balancer Details

Load Balancer page summarizes all the information of the virtual servers and the pools that are created on the load balancer.

You see,

- list of virtual servers along with its problems on the load balancer
- list of pools on the load balancer and their associated problems
- Alerts associated with the load balancer
- list of flows, count and its network traffic on different destination IPs.
- the properties of the load balancer that provides information such as the vendor, type, serial number, virtual servers, pools.

## Viewing VM Details

You can use the VM page to get a detailed overview of your VMs available in VCF Operations for networks.

In the VM page, you see the following sections:

| Section | Details |
|---|---|
| **Overview** | You see,<br>• VM details.<br>• topology information.<br>• various configuration parameters.<br>• security-related parameters.<br>• VM to Internet path. |
| **Neighbors** | You see,<br>• the graphical view of various metric properties in comparison with the neighbor VMs<br>• the list of VMs belongs to the same host. |
| **Alerts** | You see the list of alerts related to the selected VM. |
| **Flows** | You see the list of flows which are either originated or trying to reach the selected VM for which firewall action is allowed and denied. Also, you see list of the flows that are originated or trying to reach a VM with App-Id info. |

| Section | Details |
| --- | --- |
| **Metrics** | You see,<br>• the metrics information related to the selected VM.<br>• information about the network usage of ports in the path to ToR.<br>• information about all the metrics properties.<br>• Input - output metrics information.<br>• the virtual disk space.<br>• the datastore performance<br>**Note:** You cannot see the datastore metrics of a VM if it is hosted on vSAN datastore.<br>• the latency metric collection details.<br>**Note:** To see virtual infrastructure latency, the port 1991 must be open on the collector to receive latency data from the ESX host.<br>• the network utilization metrics.<br>**Note:** The metrics support 20 seconds granularity and these metrics are retained only for 48 hours. |

## Viewing NSX Manager Details

You can use the **NSX Manager** page to get a detailed overview of your NSX Manager available in VCF Operations for networks.

### How to access the NSX Manager page

To access this page, search for `NSX Manager where SDDC Type = 'VMC'` and in the search result list, click the **NSX Manager** page you want to view.

### Overview

In the **NSX Manager** page, you see the following section:

**Table 1330:**

| Section | Details |
|---|---|
| **Overview** | You see:<br>• NSX policy entities overview details.<br>• Modified entities in last 24hours.<br>• Top flows by rule.<br>• List of routers.<br><br>**Note:**<br>The number of entities shown in the **NSX Policy Entities Overview** widget and the **Entities in last 24 hours** widget can differ. If some entities discovered in the last 24 hours were deleted, then the number of entities shown in the **Entities in last 24 hours** widget can be greater than the number of entities shown in the **NSX Policy Entities Overview** widget. |
| **Top Talkers** | You see:<br>• Top talking entities in your environment. |
| **Network Traffic and Alerts** | You see:<br>• Network traffic and alerts overview details.<br>• List of alerts. |

## Viewing VMware NSX Manager Details

You can use the **VMware NSX-T Manager** page to get an overview of your VMware NSX-T Manager available in VCF Operations for networks.

To access this page, search for `NSX-T Manager` and in the search result list, click the entity you want to view.

### Overview

In the NSX Manager page, you see:

| Section | Details |
|---|---|
| **Overview** | You see:<br>• A summary of your NSX-T Manager, including the alert chart, number of firewall rules, IPSET, transport zones, applications, and unprotected flows, and flows volume in last 24 hours.<br>• List of properties, firewall rules by number of hits, top flows by rule, and compute managers.<br>• The topology details. Topology provides a contextual view of the entities and also shows alerts associated with the entities.<br>• Top flows by App-Id. |
| **Alert** | You see:<br>• A list of various alerts and analytics threshold alerts. |
| **Flows** | You see:<br>• Various flow analytics. |
| **Metrics** | You see:<br>• NSX-T Management node health details.<br><br>**Note:**<br>The NSX-T Management node health details is available only for NSX-T version 2.4.0 and later. |

## Viewing NSX-T Management Node Details

You can use the **NSX-T Management Node** page to get an overview of your VMware NSX-T Management node details available in VCF Operations for networks.

To access this page, search for `NSX-T Management Node` and in the search result list, click the entity you want to view.

### Overview

In this page, you see:

| Section | Details |
|---|---|
| **Overview** | You see:<br>• A summary of your NSX-T management node, including properties details, system metrics, and service status. |
| **Event** | You see:<br>• A list of various events. |
| **Interface Stats** | You see:<br>• Various interface stats, including received packets, transmitted packets, received dropped packets, transmitted dropped packets and so on. |
| **System Stats** | You see:<br>• Various system stats, including system load, system usage, and file system usage. |

## Viewing Switch Port Details

You can use the Switch Port page to get a detailed overview of the switch ports available in VCF Operations for networks.

To access this page, search for `Switch Port` on the VCF Operations for networks home page. The search result lists all the switch ports on VCF Operations for networks. Click the entity for which you want to view further details.

| Section | Details |
|---|---|
| Overview | You see:<br>• Key configurations and runtime properties of the switch port.<br>• A list of VMs connected to the switch port. |
| Alerts | You see the problems and changes associated with the switch port. |

| Section | Details |
| --- | --- |
| Metrics | You see the following switch port metrics:<br>• **Network Rx Rate** - The average rate at which data was received during the time interval.<br>• **Network Traffic Rate** - The average of received and transmitted traffic during the time interval.<br>• **Network Tx Rate** - The average rate at which data was transmitted during the time interval.<br>• **Dropped Rx Packets** - The average ratio of dropped received packets to total received packets.<br>• **Dropped Tx Packets** - The average ratio of dropped transmitted packets to total transmitted packets.<br>• **Interface Peak Buffer Utilization** - Peak buffer occupancy per port during the time interval.<br>• **uRPF Drop Packets** -The number of packets dropped at the switch port due to unicast reverse-path forwarding (uRPF).<br>**Note:**<br>The number of dropped packets is displayed in the metrics only if you are viewing the switch port details of a Cisco ASR 1K device and if the uRPF feature is enabled on the device. |

## Viewing Router Interface Details

You can use the Router Interface page to get a detailed overview of your router interfaces available in VCF Operations for networks.

To access this page, search for `Router Interface` on the VCF Operations for networks home page. The search result lists all the router interfaces on VCF Operations for networks. Click the entity for which you want to view further details.

| Section | Details |
| --- | --- |
| Overview | You see:<br>• Key configurations and runtime properties of the router interface.<br>• A list of VMs on the same network as this router interface.<br>• A list of VMs on the same gateways as this router interface.<br>• A list of VMs on same the network, but different gateways.<br>• A list of other router interfaces which are on same network. |
| Alerts | You see the problems and changes associated with the router interface. |

| Section | Details |
|---|---|
| Metrics | You see the following router interface metrics:<br>• **Rx packets** - The average number of received packets during the time interval.<br>• **Network Max Tx Rate** - The maximum rate at which the data is transmitted during the time interval.<br>• **Network Max Rx Rate** - The maximum rate at which the data is received during the time interval.<br>• **Tx Packets** - The average number of transmitted packets during the time interval.<br>• **Dropped Rx Packets** - The average ratio of dropped received packets to total received packets.<br>• **Dropped Tx Packets** - The average ratio of dropped transmitted packets to total transmitted packets.<br>• **Rx Bytes** -The total number of bytes received over the router interface.<br>• **Tx Bytes** -The total number of bytes transmitted over the router interface.<br>• **uRPF Drop Packets** -The number of packets dropped at the router interface due to unicast reverse-path forwarding (uRPF).<br>**Note:**<br>The number of dropped packets is displayed in the metrics only if you are viewing the router interface details of an NSX device and if the uRPF feature is enabled on the device. |

## Viewing NSX-T Transport Details

You can use the **NSX-T Transport Node** page to get an overview of your transport node details available in VCF Operations for networks. You can view both host node details and Edge node details in VCF Operations for networks.

### NSX-T Transport Node page where the node type is Host

To access this page, search for `NSX-T Transport Node where Node Type = 'HostNode'` and in the search result list, click the entity you want to view.

### Overview

In this page, you see:

| Section | Details |
|---|---|
| **Overview** | You see:<br>• A summary of your host transport node, including the alert chart, incoming traffic, outgoing traffic, internal traffic, number of network interfaces, and number of total VMs.<br>• Properties details, transport node status, PNIC statistics in last 24 hours, TEP statistics in last 24 hours, and system metrics in last 24 hours.<br>**Note:**<br>The system metrics is available only for NSX-T version 2.4.0 and later. |
| **Alert** | You see:<br>• A list of various alerts. |
| **Latency** | You see:<br>• TEP to TEP latency details. |

| Section | Details |
|---|---|
| **Interface Stats** | You see:<br>• Various interface stats, including received packets, transmitted packets, received dropped packets, transmitted dropped packets and so on. |
| **System Stats** | You see:<br>• Various system stats, including system load, system usage, and file system usage.<br>**Note:**<br>The **System Stats** is available only for NSX-T version 2.4.0 and later. |
| **Flows** | You see:<br>• Top VMs by flows (in last 24 hours) and top rules by flows (in last 24 hours). |

**NSX-T Transport Node page where the node type is Edge**

To access this page, search for `NSX-T Transport Node where Node Type = 'EdgeNode'` and in the search result list, click the entity you want to view.

**Overview**

In this page, you see:

| Section | Details |
|---|---|
| **Overview** | You see:<br>• A summary of your Edge transport node, including the alert chart, number of network interfaces, tier0 service routers, tier1 service routers, and routes.<br>• Properties details, transport node status, uplink statistics in last 24 hours, TEP statistics in last 24 hours, and system metrics in last 24 hours |
| **Alert** | You see:<br>• A list of various alerts. |
| **NAT Stats** | You see:<br>• Various NAT stats, including NAT Rule Statistics, top NAT rules by total bytes, top NAT rules by total packets, and top NAT rules by session count. |
| **Interface Stats** | You see:<br>• Various interface stats, including received packets, transmitted packets, received dropped packets, transmitted dropped packets and so on. |
| **System Stats** | You see:<br>• Various system stats, including system load, system usage, and file system usage. |

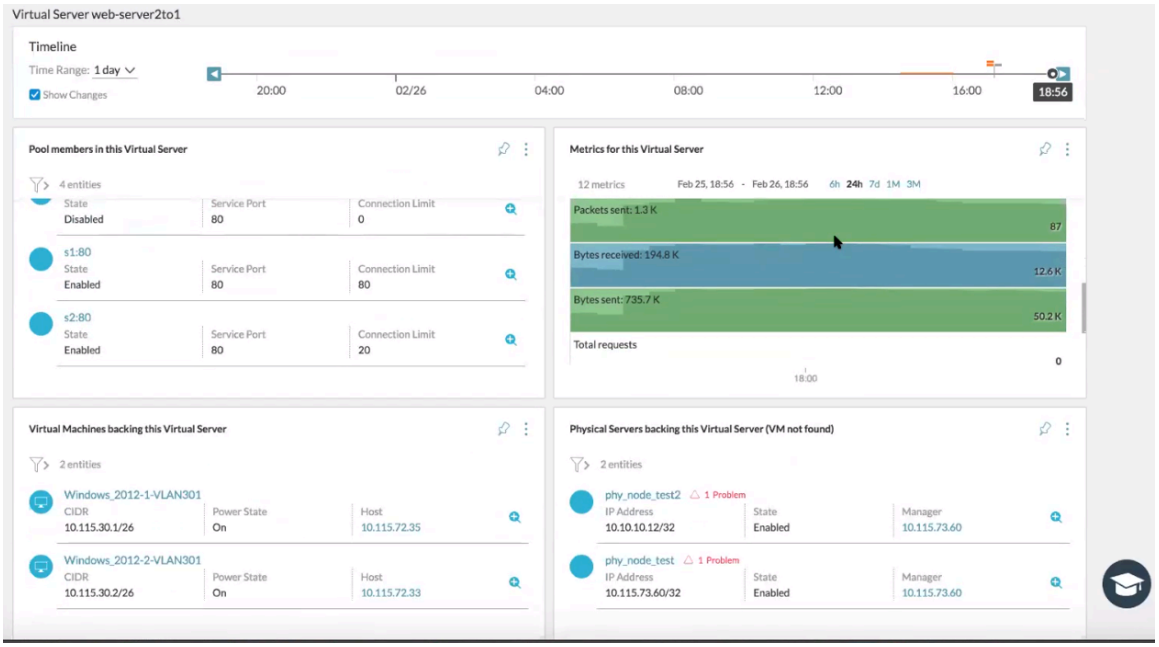
## Viewing Virtual Server Details

The Virtual Server page displays the virtual server metrics, problems, and change alerts.

You see,

- The list of all pool members in the virtual server and its details, along with an alert for any problem.

- The list of virtual machines
- The list of physical servers
- The list of problem alerts that are associated with the virtual server .
- The list of metrics that are related to the virtual server, such as:
  - Connections (count, duration)
  - Network metrics (packets and bytes received or sent)
  - CPU usage
- The top flows for the pool members used by the virtual server.
- The virtual server properties that provides information about the load balancer IP address, network traffic, service port.



To view the path topology associated with the load balancer, you can use the following query:

*client VM name* to *Virtual server IP*.

If there are multiple virtual servers on different service ports, you see the list under the **Select a Destination VM** section. To see the VM to virtual server path, you can select a server from the list and click **Show Path**.

To see a set of VMs on the Virtual Server window, you can click the virtual server on the VM path topology and click **View Path** to see the path from virtual server to the selected VM.

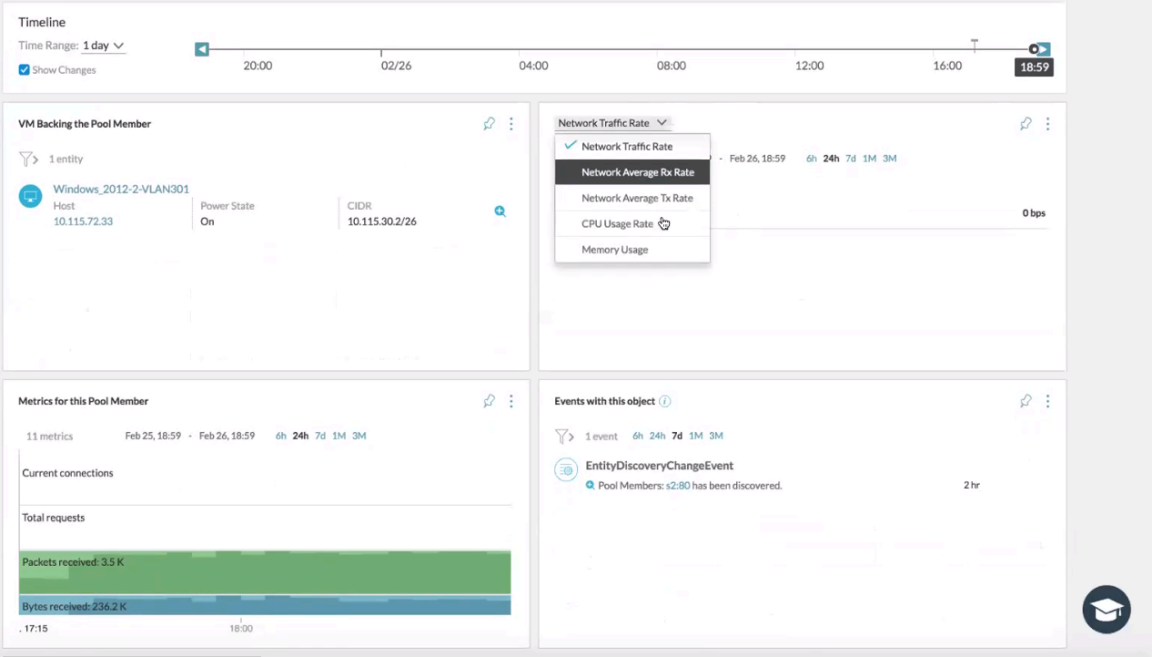
## Viewing Pool Members Details

The Pool Member page provides insight about the pool members, metrics, and alerts associated with the pool member.

You see:

- The list of virtual machines and additional details about the VM
- The list of metrics that are related to the pool member, such as:
  - Connections (count, duration, age )
  - Network metrics (packets and bytes received or sent)
  - CPU usage
- The pool member properties that provide information about the load balancer, node, status, service port.

The Pool Member page also allows you to compare the metrics of the pool member with the metrics of the VM. For example, memory and CPU usage, Network traffic, and so on.



## Viewing Microsoft Azure Details

You can use the **Microsoft Azure** page to get a quick overview of your Azure environment details in VCF Operations for networks.

### How to access

To access this page, on the search bar, enter `Azure`.

> **Note:**
>
> Starting with version 9.1.1, adding new **Microsoft Azure** data sources is not supported. **Microsoft Azure** data sources configured before version 9.1.1 are disabled. Data collection for these data sources has stopped, and they cannot be enabled. Dashboards only display historical data was collected from previously configured **Microsoft Azure** data sources.

### Overview

In this page, you see:

- List of subscriptions
- List of virtual machines
- List of network interfaces, virtual networks, subnets, route tables, and routes
- List of network security groups, application security groups, and NSG rules.

You can also click the entities on this page to the see more detailed insight about the particular entity.

In addition to the **Microsoft Azure** page, you can see the insight about the following Azure entities:

**Table 1331: Azure Entity details**

| Entity name | Description |
|---|---|
| **Azure Application Security Group** | You see:<br>• List of properties, alerts, associated VMs, and associated VMs for last 24 hours.<br>• List of incoming NSG rules and outgoing NSG rules.<br>• List of allowed flows, denied flows, flows for last 24 hours. |
| **Azure Data Source** | You see:<br>• List of properties, alerts, and metrics. |
| **Azure NSG Rules** | You see:<br>• List of properties, alerts, and metrics. |
| **Azure Network Interface** | You see:<br>• List of properties, alerts, and metrics. |
| **Azure Network Security Group** | You see:<br>• List of properties, alerts, NICs, and subnet.<br>• List of outbound rules and inbound rules.<br>• List of allowed flows, denied flows, flows for last 24 hours. |
| **Azure Route** | You see:<br>• List of properties, alerts, and metrics. |
| **Azure Route Table** | You see:<br>• List of properties, alerts, and metrics. |
| **Azure Subnet** | You see:<br>• List of properties, alerts, VMs, NICs, and custom routes.<br>• List of NSG rules. |
| **Azure Subscription** | You see:<br>• List of properties and alerts.<br>• List of virtual machines.<br>• List of NICs, virtual networks, and route table<br>• List of network security groups, application security groups, and NSG Rules. |
| **Azure Virtual Machine** | You see:<br>• List of properties, alerts, NICs, associated Application Security Groups (ASGs).<br>• List of incoming NSG rules and outgoing NSG rules.<br>• List of allowed flows and denied flows. |
| **Azure Virtual Network** | You see:<br>• List of properties, alerts, VMs, VMs created in last 24 hours, associated ASGs, associated ASGs for last 24 hours, subnets, and route tables.<br>• List of allowed flows, denied flows, and flows for last 24 hours. |

## Viewing Internet Service Provider Details

You can use the **Internet Service Provider** page to Internet Service Provider(ISP) visibility across all the edges of an enterprise?.

To access this page, search `Internet Service Provider` and in the search result list, click the entity you want to view.

| Section | Details |
|---|---|
| **Overview** | You see:<br>• List of VeloCloud Edges, quality of experience reports on Edges and Links, packets details, latency details, and flow packets details. |

## Viewing VMC SDDC Details

You can use the **VMC SDDC** page to get an overview of your VMC on AWS SDDC in VCF Operations for networks.

### How to access the VMC SDDC page?

To access this page, search for `VMC SDDC` and in the search result list, select an entity you want to view.

### Overview

In the **VMC SDDC** page, you see:

| Section | Details |
|---|---|
| **Overview** | You see an overview of your NSX Entities and the count of Direct Connect Interface (VIFs) present within SDDC.<br>You see entities in last 24 hours, Top flows by rule which also shows the firewall manager responsible for the firewall rule, list of routers, and properties details.<br>You also can see the top 25 VMs based on the resource pool, metrics, and aggregate type. |
| **Microsegmentation** | You see the graphical representation of flows between entities. |
| **Network Traffic and alerts** | You see an overview of the network traffic and the list of all alerts associated with the SDDC entities discovered by VCF Operations for networks alerts. |
| **Top Talkers** | You can see the top talking entities in VMC SDDC. |
| **Metrics** | You see the Tier0 Router interface metrics, such as Rx Packets, Tx Packets, Dropped Rx Packets, and so on for Public, Cross-VPC, and Direct Connect interfaces.<br>You see Network Utilization metrics.<br>You see Entity Usages metrics which show metrics related to various distributed firewall rules. The Entity Usages metrics also shows the alert threshold and the maximum value by colored dash lines.<br>**Note:**<br>The metrics support 20 seconds granularity and these metrics are retained only for 48 hours. |

### VMC SDDC Limits

The following messages are displayed when the VMC SDDC exceeds the network and security maximum limits:

| Message | Severity | Alert Name |
|---|---|---|
| Number of IPsec VPN tunnels created per SDDC | Info | VMware Cloud Threshold Alert |

| Message | Severity | Alert Name |
|---|---|---|
| Number of logical segments per SDDC | Critical | |
| Number of Management Gateway firewall rules | Critical | |
| Number of Compute Gateway firewall rules | Critical | |
| Number of grouping objects (security groups) | Critical | |
| Number of private virtual interfaces attached to one SDDC | Info | |
| Number of distributed firewall rules per section group | Critical | |
| Number of distributed firewall rules across all categories | Critical | |
| Number of distributed firewall Sections per categories | Critical | |
| Number of distributed firewall sections across all categories | Critical | |

**Related Topic**

VMC SDDC Search Queries

You can search the VMware Cloud on AWS SDDC ( Software-defined data center) entity details in VCF Operations for networks.

## Viewing VMC on AWS Outposts SDDC Details

The **VMC on AWS Outposts SDDC** page provides a detailed overview of an SDDC hosted within AWS facilities.

### How to access the VMC on AWS Outposts SDDC page?

To access this page, do one of the following:

- Search for `VMC on AWS Outposts SDDC` and in the search result list, select an SDDC you want to view.
- Select **VMC on AWS Outposts** on the **Environments** widget of the homepage. From the list, select the SDDC you want to view.

### Overview

In the **VMC on AWS Outposts SDDC** page, you see:

| Section | Details |
|---|---|
| **Overview** | You see the following information:<br>• The number of entities within the SDDC which includes number of VMs, groups, firewall rules, and policy based VPNs.<br>• Important configuration and runtime properties of the SDDC.<br>• Entities discovered in the last 24 hours.<br>• The top firewall rules based on flow traffic.<br>• The top 25 VMs based on a selected metric and aggregate type. |
| **Microsegmentation** | You see the graphical representation of flows between entities. |
| **Network Traffic and alerts** | You see an overview of the network traffic and the list of alerts related to the SDDC. |
| **Top Talkers** | You see the top talking VMs in the SDDC. |

| Section | Details |
| --- | --- |
| **Metrics** | You see the following metrics:<br>• Tier0 router interface metrics such as Rx Packets, Tx Packets, Dropped Rx Packets for public, cross-VPC, and direct connect interfaces.<br>• Network utilization metrics.<br>**Note:**<br>The network utilization metric supports 20 seconds granularity and its retention interval is 48 hours.<br>• Entity usage metrics on various distributed firewall rules. |

## Viewing Arista Hardware Gateway and Arista Hardware Gateway Binding Details

You can view the **Arista Hardware Gateway** and **Arista Hardware Gateway Binding** page to get an overview of your Arista Hardware Gateways.

### How to access the Arista Hardware Gateway page?

To access the **Arista Hardware Gateway** page, search for `Arista Hardware VTEP` and in the search result list, click the entity you want to view.

To access the **Arista Hardware Gateway Binding** page, search for `Arista Hardware Gateway Binding` and in the search result list, click the entity you want to view.

### Overview

In the **Arista Hardware Gateway** page, you see:

- List of alerts
- List of key properties
- List of Arista hardware gateway bindings.

In the **Arista Hardware Gateway Binding** page, you see:

- List of alerts
- List of properties.

## Viewing Avi Load Balancer Details

You can use the Avi Load Balancer entity pages to get detailed insight of Avi Load Balancer entities such as cluster, data source, tenant, controller, pool, virtual service, service engine, and analytics profile.

### How to Access Avi Load Balancer Entity Pages?

To access Avi Load Balancer entity pages:

1. Enter `NSX-ALB` in the Search bar.
2. In the search result, click the entity type that you want to view, and press **Enter**.
3. On the respective entity type page, click the name of the entity for which you want to view the details.

Alternatively, select **Entities** on the left navigation pane and enter `ALB` or `NSX-ALB` in the entity search bar.

## Avi Load Balancer Entity Details Pages

| Entity Name | Description |
|---|---|
| **NSX-ALB Cluster** | You see the deployment details at the cluster level, which includes:<br>• Summary of open alerts<br>• Count of Tenants, Clouds, Service Engines, Service Engine Groups, Virtual Services, Pools and Pool Members in the deployment.<br>• List of key properties<br>• List of Controllers<br>• List of alerts encountered in the last seven days<br>• Health of Virtual Services<br>• Graphical representation of the following metrics:<br>– Controller Metrics<br>– Service Engine Metrics<br>– Virtual Service Metrics<br>– Pool Metrics |
| **NSX-ALB Data Source** | You see the details of the data source which includes:<br>• List of key properties<br>• List of open problems<br>• List of all the changes and the problems encountered in the last seven days |
| **NSX-ALB Controller** | You see the details of the controller which includes:<br>• List of key properties<br>• List of alerts encountered in the last seven days<br>• Graphical representation of the CPU Usage Metrics<br>**Note:**<br>You have to be a super user to view this metrics. |
| **NSX-ALB Tenant** | You see the details of the tenant which includes:<br>• Summary of open alerts<br>• Count of Service Engines, Service Engine Groups, Virtual Services, Pools and Pool Members in the deployment.<br>• List of key properties of the tenant<br>• List of alerts encountered in the last seven days<br>• Graphical representation of the following metrics:<br>– Virtual Service Metrics<br>– Service Engine Metrics<br>– Pool Metrics |
| **NSX-ALB Cloud** | You see the deployment details at the Cloud level which includes:<br>• Summary of open alerts<br>• Count of Service Engines, Service Engine Groups, Virtual Services, Pools and Pool Members in the deployment.<br>• List of key properties<br>• List of open alerts encountered in the last seven days<br>• Graphical representation of the following metrics:<br>– Service Engine Metrics<br>– Virtual Service Metrics<br>– Pool Metrics |

| Entity Name | Description |
|---|---|
| **NSX-ALB Service Engine Group** | You see the details of the Service Engine Group which includes:<br>• Summary of open alerts<br>• Count of Service Engines, Virtual Services, Pools and Pool Members in the deployment.<br>• List of key properties<br>• List of alerts encountered in the last seven days<br>• Graphical representation of the following metrics:<br>– Virtual Service Metrics<br>– Service Engine Metrics<br>– Pool Metrics |
| **NSX-ALB Service Engine** | You see the details of the Service Engine which includes:<br>• Summary of open alerts<br>• Count of Virtual Services, Pools, and Pool Members<br>• List of alerts encountered in the last seven days<br>• Graphical representation of the following metrics:<br>– Virtual Service Metrics<br>– Service Engine Metrics<br>– Pool Metrics |
| **NSX-ALB Virtual Service** | You see the details of the Virtual Service which includes:<br>• List of key properties<br>• List of Pool Members<br>• List of VMs associated with the Virtual Service<br>• List of Pool Members associated with this Virtual Service by Sum of Connections<br>• List of alerts encountered in the last seven days<br>• Graphical representation of the Virtual Service Metrics |
| **NSX-ALB Pool** | You see the details of the pool which includes:<br>• List of key properties<br>• List of Pool Members associated with the pool<br>• List of VMs in the pool<br>• List of alerts encountered in the last seven days<br>• Graphical representation of the Pool Metrics |
| **NSX-ALB Pool Member** | You see the details of the pool member which includes:<br>• List of key properties<br>• Details of the VM that is backing the Pool Member<br>• List of alerts encountered in the last seven days<br>• Graphical representation of VM and Pool Metrics |
| **NSX-ALB Pool Group** | You see the details of the Pool Group which includes:<br>• List of key properties<br>• List of alerts encountered in the last seven days<br>• Graphical representation of the Pool Metrics |
| **NSX-ALB Analytics Profile** | You see the detailed analytics of Avi Load Balancer which includes:<br>• List of key properties<br>• List of alerts encountered in the last seven days<br>• List of Virtual Services |

## Viewing Cisco Nexus Device Details

You can use the **Cisco Nexus Device** page to get an overview of your cisco nexus device available in VCF Operations for networks.

**Overview**

In this page, you see:

- Performance monitoring metrics.

  **Note:**
  To get more insight about each metric, click the individual metric value.
- Alert list.
- Properties details.
- List of switch ports, switch port peers, and VMs connected to port.
- Switch port metrics.

## Viewing Micro-Segmentation Details

You can analyze the flows by selecting scope and segment them accordingly based on entities such as VLAN/VXLAN, Security Groups, Application, Tier, Folder, Subnet, Cluster, virtual machine (VM), Port, Security Tag, Security Group, and IPSet.

The micro-segmentation page provides the analysis details with the topology diagram. This page consists of the following sections:

- Micro-Segments: This widget provides the diagram for topology planning. You can select the type of group and flows. Based on your inputs, you can view the corresponding topology planning diagram.
- Traffic Distribution: This widget provides the details of the traffic distribution in bytes.
- Top Ports by Bytes: This widget lists the top 100 ports that record the highest traffic. The metrics for the flow count and the flow volume are provided. You can view the flows for a particular port by clicking the count of flows corresponding to that port.

To access the micro-segmentation page:

1. In the left navigation panel, click **Security > Plan Security**.
2. Select the scope, subscope, and the duration for which you want to plan and analyze. Click **Analyze**.

   The micro-segmentation page appears.

   **Note:**
   The micro-segmentation wheel view can show upto 600 nodes and 6000 edges. If the limit exceeds, you see the `Too many micro-segments to analyse. Please select a different entity or micro-segmentation criteria` error.

## Viewing VMware HCX Manager Details

You can view the VMware HCX Manager details deployed per VMware vCenter.

To access the VMware HCX Manager page, from the left navigation pane, go to **Environments** and select **VMware HCX Manager**. Alternatively, search **HCX Manager** to list all the VMware HCX Managers. VCF Operations for networks also supports search for all the VMware HCX entities.

The VMware HCX Manager page displays the list of sites, click any of the sites to open the VMware HCX Manager details page of that site.

In the VMware HCX Manager details page you see the following sections.

| Section | Details |
| --- | --- |
| Overview | • In the **Summary** widget, you see the total number of alerts, appliances, services meshes, L2 extensions, tunnels, and applications communicating over the L2 extension in that site.<br>Click the total number on any of these categories to see the associated entities and its details.<br>• In the VMware HCX Appliance Topology widget:<br>  • The **Interconnect** tab shows the sites paired with the current VMware HCX Manager site. Here, the current VMware HCX Manager site is shown at the top and the sites paired are shown at the bottom.<br>  Hover over the connection between the sites to see information about the source appliance, destination appliance, unhealthy tunnels, and the total number to tunnel entities.<br>  If any tunnels have any alerts raised, you can click the number of unhealthy tunnels to view those details. Click the total number of tunnels to see the tunnel entity details.<br>  • The **Network Extension** tab shows the topology of how the networks are extended from the current VMware HCX Manager site to the paired sites.<br>  This topology shows the network extension appliance pairs between the sites connected via tunnels, the L2 networks that are extended via these appliances, and the VMs that belong to these L2 networks. Hover over any of the appliance, L2 networks, VMs, or tunnels to view more details.<br>  **Note:**<br>  You can sometimes see appliances that not connected to any appliances on the paired sites. This occurs when the VMware HCX data source for the paired site of that appliance is not added to VCF Operations for networks.<br>  • You can also filter the topology map to show the entities (with their connections) that have critical alerts.<br>In the **Interconnect** tab and the **Network Extension** tab, click on the site to expand it and only one paired site can be in the expanded state.<br>**Note:**<br>Only the sites that are added as VMware HCX data sources in VCF Operations for networks are shown in these tabs. |
| Alerts | You see the list of various alerts raised based on the health of the VMware HCX entities and any misconfigurations between the paired VMware HCX sites. |

| Section | Details |
| --- | --- |
| Flows | VCF Operations for networks identifies the flows going over the VMware HCX network extension tunnels and enriches them with the information of the VMware HCX L2 extension entity.<br>• **Top Talking Entities Over L2 Extensions**: In this widget, you can see the top talking entities like VM pairs, L2 networks, VMware HCX L2 extensions, etc over the network extension tunnels that belong to the current VMware HCX Manager.<br>• **Flows Per L2 Extensions**: In this widget, you see the number of flows and the related flow metrics for each L2 extension entity in the current VMware HCX Manager.<br>• **Tromboning Flows Per L2 Extension**: In this widget, you see the tromboning flows that traverse from the remote site to the local site and then back to the remote site via the network extension tunnels.<br>This helps you to identify if you want to enable Mobility Optimized Networking on the participating L2 extensions so that the flows from VMs in the remote sites can directly traverse over the remote gateway.<br>• **Flows Per Appliance Pair**: In this widget, you see the flows over the network extension tunnels and related metrics grouped by the network extension appliance pairs. |
| Metrics | You see the metrics details of the VMware HCX appliances VMs and hosts, tunnels, and appliance VM network utilization. |

In addition to the VMware HCX Manager details page, you can also see the insights about the VMware HCX entities. You can access the VMware HCX entity pages from the VMware HCX Manager details page or directly search for them in the VCF Operations for networks search.

### VMware HCX Site

You see the list of properties and alerts of the selected VMware HCX Site.

### VMware HCX Service Mesh

VMware HCX service mesh is a group of VMware HCX services deployed between two site.

In the **Flows** tab of this VMware HCX Service Mesh entity page, VCF Operations for networks identifies the flows going over the HCX network extension tunnels and enriches them with the information of the VMware HCX L2 extension entity.

- **Top Talking Entities Over L2 Extensions**: In this widget, you can see the top talking entities like VM pairs, L2 networks, VMware HCX L2 extensions, etc over the network extension tunnels that belong to the current VMware HCX Manager.
- **Flows Per L2 Extensions**: In this widget, you see the number of flows and the related flow metrics for each L2 extension entity in the current VMware HCX Manager.
- **Tromboning Flows Per L2 Extension**: In this widget, you see the tromboning flows that traverse from the remote site to the local site and then back to the remote site via the network extension tunnels.
  This helps you to identify if you want to enable Mobility Optimized Networking on the participating L2 extensions so that the flows from VMs in the remote sites can directly traverse over the remote gateway.
- **Flows Per Appliance Pair**: In this widget, you see the flows over the network extension tunnels and related metrics grouped by the network extension appliance pairs.

In this entity page you also see:

- List of properties and alerts.
- List of all the VMware HCX service and tunnel entities under that service mesh.

Click any entity to view more details.

### VMware HCX Service

VMware HCX service is a part of the service mesh that is responsible for the VMware HCX features like interconnect, network extension, bulk migrations, etc.

In this entity page, you see a list of all the properties and alerts of the selected VMware HCX service.

### VMware HCX Appliances

VMware HCX appliance is a VM that runs the VMware HCX services. VCF Operations for networks supports VMware HCX interconnect appliance, VMware HCX network extension appliance, and the VMware HCX WAN optimisation appliance.

In the **Flows** tab of this VMware HCX Appliances entity page, VCF Operations for networks identifies the flows going over the HCX network extension tunnels and enriches them with the information of the VMware HCX L2 extension entity.

- **Top Talking Entities Over L2 Extensions**: In this widget, you can see the top talking entities like VM pairs, L2 networks, VMware HCX L2 extensions, etc over the network extension tunnels that belong to the current VMware HCX Manager.
- **Flows Per L2 Extensions**: In this widget, you see the number of flows and the related flow metrics for each L2 extension entity in the current VMware HCX Manager.
- **Tromboning Flows Per L2 Extension**: In this widget, you see the tromboning flows that traverse from the remote site to the local site and then back to the remote site via the network extension tunnels.
  This helps you to identify if you want to enable Mobility Optimized Networking on the participating L2 extensions so that the flows from VMs in the remote sites can directly traverse over the remote gateway.
- **Flows Per Appliance Pair**: In this widget, you see the flows over the network extension tunnels and related metrics grouped by the network extension appliance pairs.

In this entity page, you also see a list of properties, alerts, and metrics for the selected VMware HCX appliance.

### VMware HCX Tunnels

VMware HCX tunnel is an overlay tunnel between the VMware HCX appliances.

In this entity page, you see a list of properties, alerts, and metrics for the selected VMware HCX tunnel entity.

### VMware HCX L2 Extension

VMware HCX L2 extension stretches an L2 network from one site to another.

In the **Flows** tab of this VMware HCX L2 Extension entity page, VCF Operations for networks identifies the flows going over the HCX network extension tunnels and enriches them with the information of the VMware HCX L2 extension entity.

- **Top Talking Entities Over L2 Extensions**: In this widget, you can see the top talking entities like VM pairs, L2 networks, VMware HCX L2 extensions, etc over the network extension tunnels that belong to the current VMware HCX Manager.
- **Flows Per L2 Extensions**: In this widget, you see the number of flows and the related flow metrics for each L2 extension entity in the current VMware HCX Manager.
- **Tromboning Flows Per L2 Extension**: In this widget, you see the tromboning flows that traverse from the remote site to the local site and then back to the remote site via the network extension tunnels.
  This helps you to identify if you want to enable Mobility Optimized Networking on the participating L2 extensions so that the flows from VMs in the remote sites can directly traverse over the remote gateway.
- **Flows Per Appliance Pair**: In this widget, you see the flows over the network extension tunnels and related metrics grouped by the network extension appliance pairs.

In this entity page, you also see a list of properties and applications with flows over the VMware HCX L2 extension.

### VMware HCX Network Profile

In this entity page, you see a list of properties and alerts for the selected VMware HCX network profile entity

### VMware HCX Compute Profile

In this entity page, you see a list of properties and alerts for the selected VMware HCX compute profile.

You can set analytics threshold events on the HCX Tunnel and the HCX Appliance Metrics. For more information about analytics thresholds, see Working with Analytics.

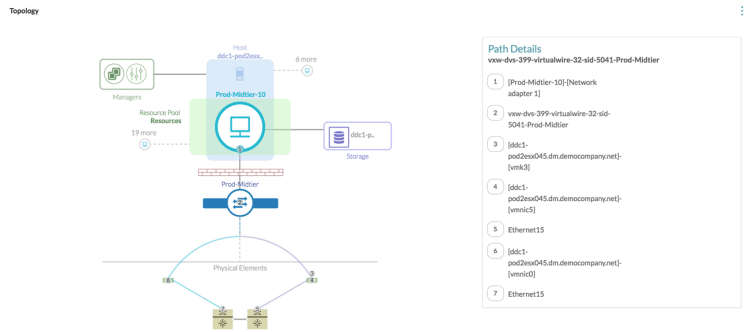
You can also use Guided Network Troubleshooting to troubleshoot VMware HCX entities from a single page. To troubleshoot VMware HCX entities, in the VMware HCX Manager details page or in any of the VMware HCX entity page, click the **Troubleshoot** icon located near the top-right corner.

## Viewing Entity Topology

The topology provides a comprehensive pictorial view of the entity.

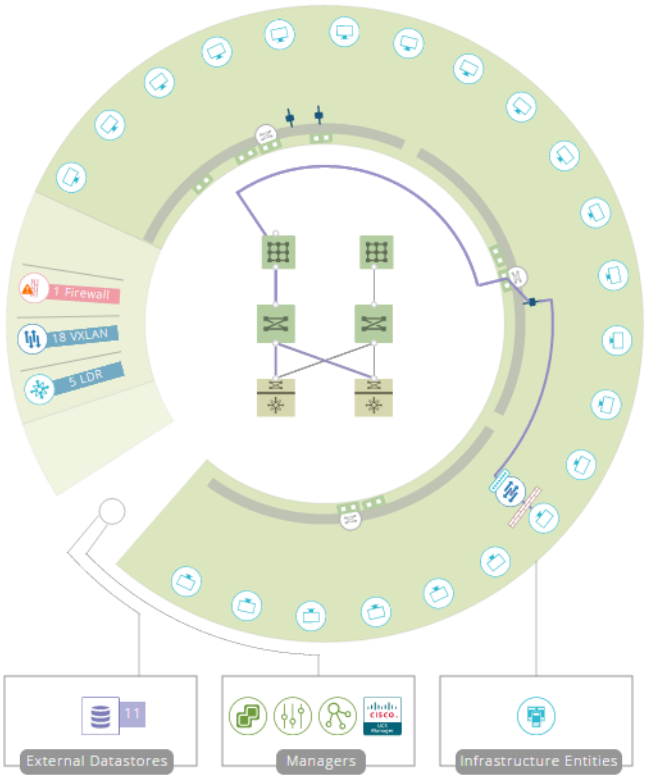
### Virtual Machine Topology

The virtual machine topology provides a comprehensive view of a singular virtual machine in relation to the rest of your data center.



### Host Topology

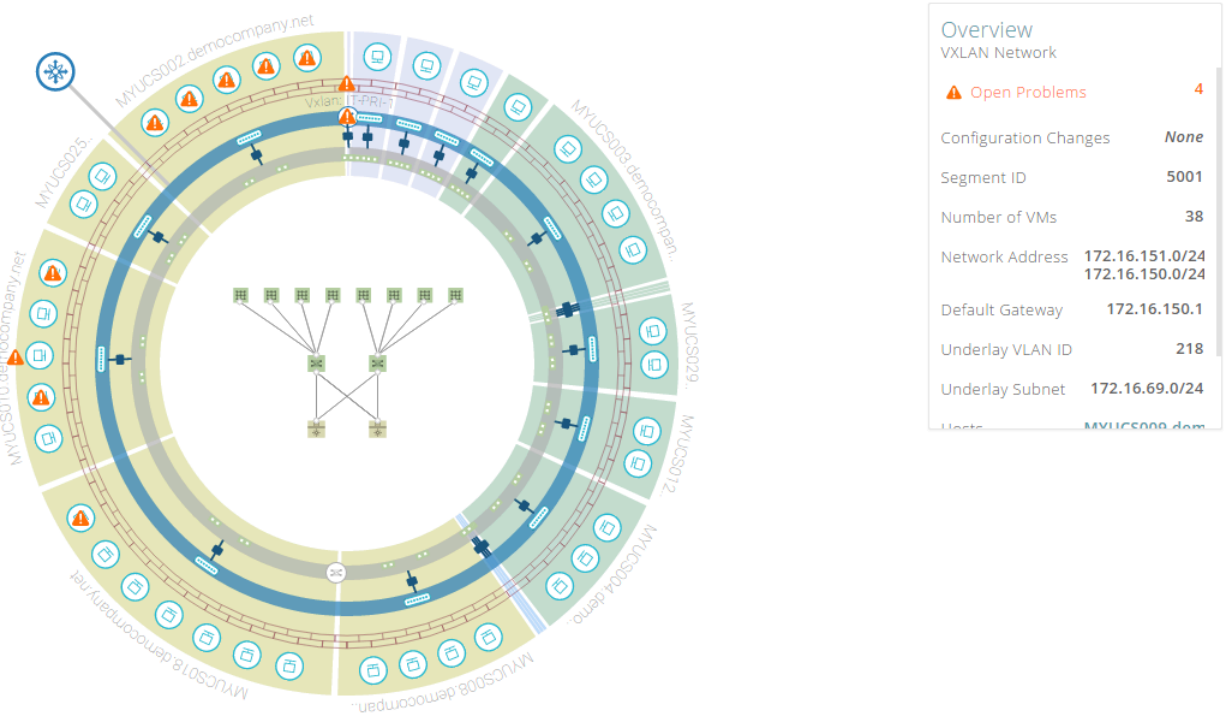
The host topology shows how VMs of a particular host are connected to the virtual and physical components of your data center and also how the host itself is connected with your data center.



## VXLAN Topology

Virtual eXtensible Local Area Network (VXLAN) overlay networking technology is an industry standard that is developed by VMware jointly with the major networking vendors.

The VXLAN topology is an innovative visualization that gives you an overview of the selected VXLAN. The following diagram elucidates the various components that make up the visualization:



**Note:**
Both virtual and physical components can be visualized in this manner.

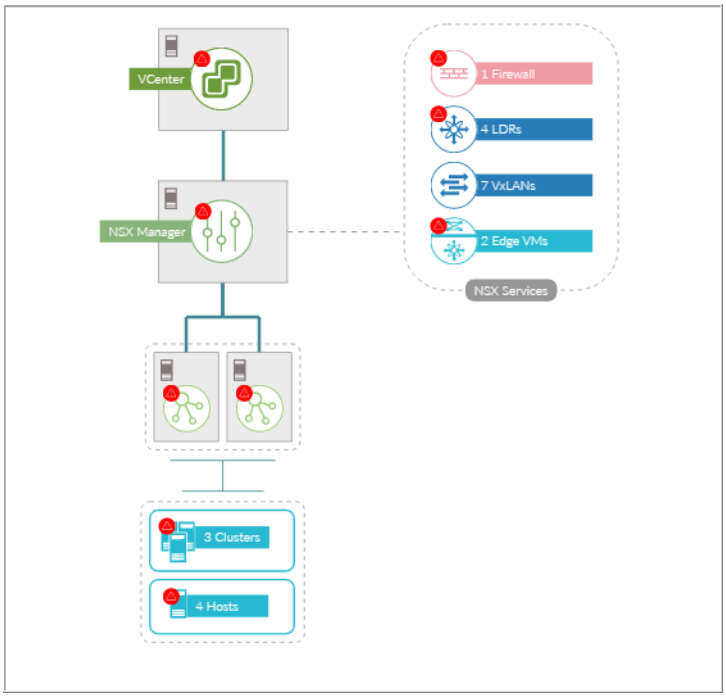
## VLAN Topology

Virtual LANs (VLANs) enable a single physical LAN segment to be further segmented so that groups of ports are isolated from one another as if they were on physically different segments.

The VLAN topology is constructed in a similar manner as the VXLAN topology.

## NSX Manager Topology

The NSX Manager topology shows the components that are associated with the NSX Manager.



**Viewing Audit Information of NSX objects in VCF Operations for networks**
VCF Operations for networks can capture an audit information of NSX objects quickly from the NSX-T Manager. The information includes the user name who created or modified the NSX object, when the operation happened and the operation details on the object.

If you have enabled audit logs in NSX-T Manager, VCF Operations for networks can collect the audit details for some of the NSX-T.

**NSX-T**

List of NSX-T objects for which VCF Operations for networks collects audit details.

**Note:**
The audit information is not available for the VMC Policy entities.

- NSGroup
- NSService
- NSServiceGroup
- NSFirewallRule

**Note:**
The audit information is not available for the Delete alert of the NSFirewallRule.

- IPSet
- NSX Policy Group
- NSX Policy Firewall Rule

**Note:**
If you are using NSX-T version 4.x and later, the following entities are not available and search wont show any result; you must update your user defined dashboards and user defined alerts using the corresponding policy entities:

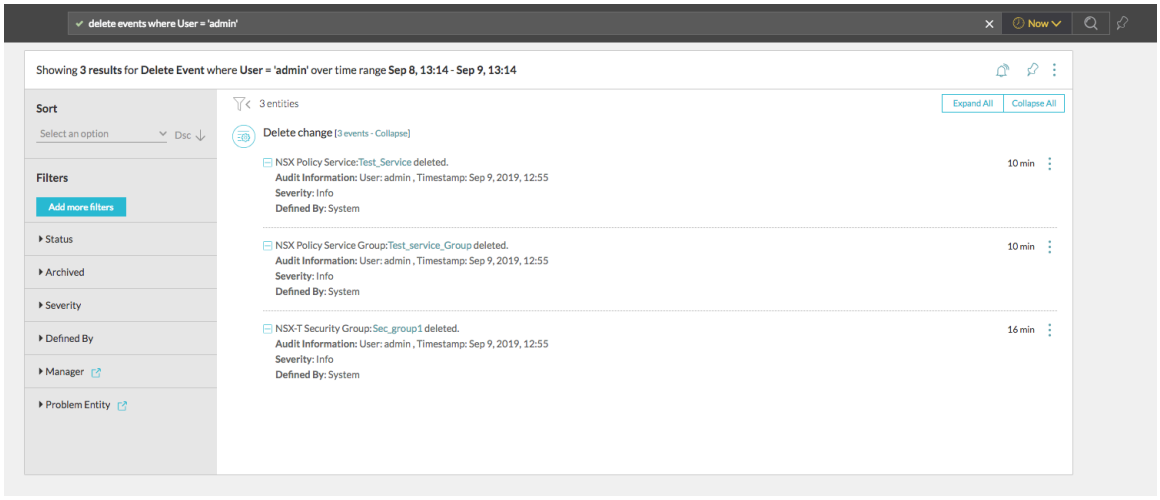
| Entities | Corresponding Policy Entities |
|---|---|
| NSGroup | NSX Policy Group |
| NSService | Policy Service entry |
| NSService Group | Policy service |
| NSX-T Firewall | NSX Policy Firewall |
| NSX-T Firewall Rule | NSX Policy Firewall Rule |
| NSX-T IPSet | IPSet |

The audit details of the NSX-T objects are captured for the Discovery, Property Change and the Delete alerts:

- `Discovery`

- `Properties Change`

- `Delete`



**Note:**
The Delete alerts are not available on the entity dashboard. However, you can search the alert to see the audit information.

**Sample queries to see audit information**

- `alerts where user = username`
- `discovery alerts where user = username`
- `delete alerts where user = username`
- `change alerts where user = username`

# Working with Pins and Dashboards

You can pin any widget on the VCF Operations for networks user interface to a new dashboard or an existing dashboard to access it quickly and easily.

## Pins

The information on each entity page is separated into pins. All the entity pages are made up of pins and each pin contains a specific bit of information related to the entity.

Pins have the following features:

- You can maximize the view of any pin using the **More options** button and also view more information about the pin using the **Help** option.
- Pins can also contain filters so that you can drill down on the data that is displayed on the pin.
- Many pins also contain the **Export as CSV** option so that you can export the data present in the pin in CSV format. You can select the specific properties and the number of CSV rows you want to export in the dialog box that is displayed.

  **Note:**
  The export as CSV feature for the flow data takes more than 30 minutes for 180,000 flows when all fields are selected.
- You can go back to the original page from the pinned page. To go to the original page, on the saved pin, click **More options** > **Go to original page**.

To add a pin, click the **Pin** icon, select the dashboard, and click **PIN**. You can find your saved pins on the **All Dashboards** page.

### Types of Pins

There are many types of pins in VCF Operations for networks. Most of the pins that are available in the software can be categorized into the following:

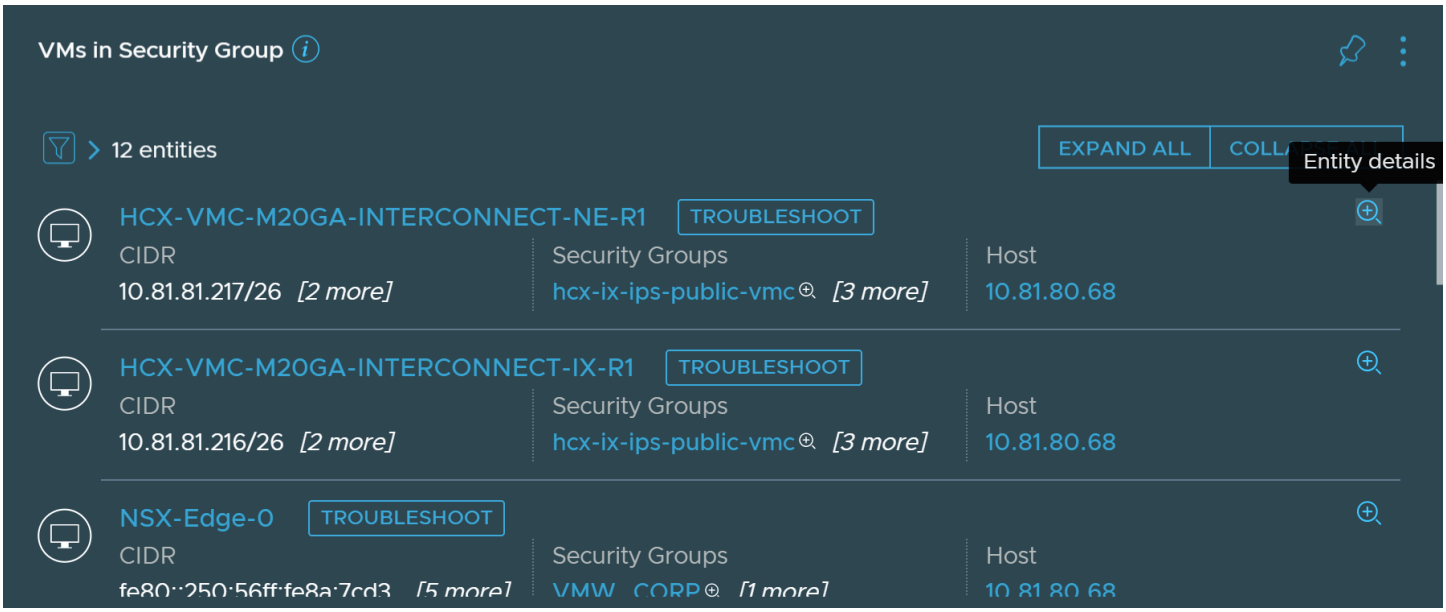
**Metrics Pins**
Metrics pins show important metrics pertaining to the selected entity.

A metrics pin uses the line graph to display data about the selected entity. You can point anywhere on the line graph to get informative tool tips. You can also co-relate multiple entities or two metrics graphs at the same time.

**Entity List View Pins**
The entity list view pins display a list of entities that are grouped by a common theme. The list shows important attributes per entity.

You can see more attributes of a particular entity by clicking the magnify icon on the far right. You can also click the entity name to navigate to the respective entity page.

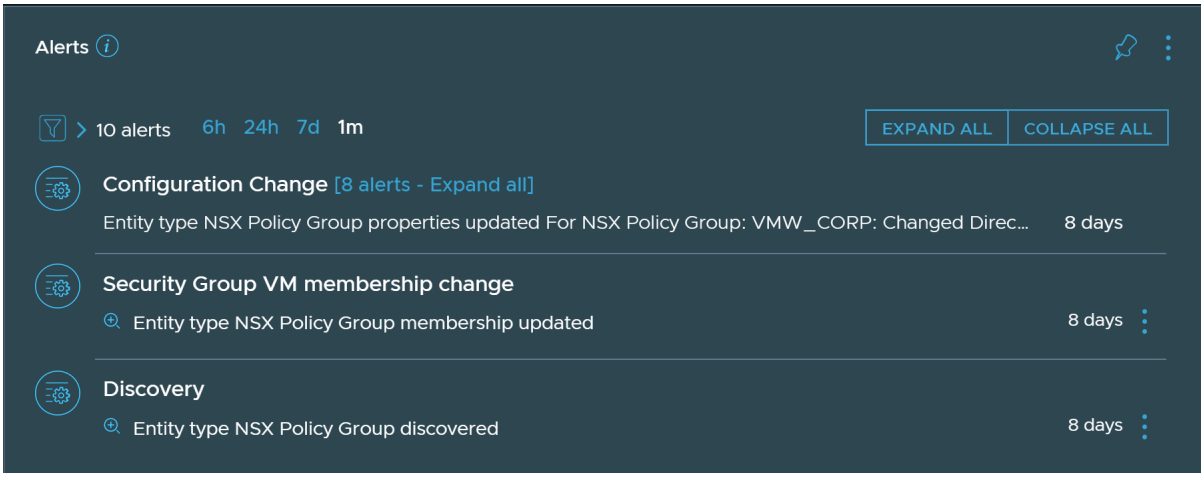
Like other pins, the filter icon houses various facets to filter the list. An example of the entry list view pin is VMs by security groups. By default, this pin shows the VMs that are part of the same security group. You can also filter VMs by properties such as VXLAN, OS hostname, vendor ID, and datastore.



**Alert View List Pins**
The alerts list view pins provide a list of alerts in the chronological order for a particular entity or group of entities.

You can change how far back in time (from now) must the pin show alerts by using the available presets or entering in a custom date/time. Other filter options such as **Alert Status** and **Alert Type** can be selected by clicking the filter icon.

Here, the alerts related to an NSX policy group are displayed. You can expand an alert and click the entity name to navigate to the entity page and view alerts related to that entity. By clicking the filter icon you can filter the alerts based on their status and type.



You can search for the alerts by using the alerts search query. You can search for open or closed alerts with queries such as open alerts or closed alerts. You can also search for problems with the same modifiers.

## Dashboards

You can create a dashboard or pin any widget from any page on a dashboard to make it easier to access and share data. Using dashboards, you can organize and present information from multiple sources in one location, and in real time.

**Note:**

Pinboards are deprecated from VCF Operations for networks version 6.9. They are replaced with dashboards.

When you upgrade to VCF Operations for networks version 6.9, your existing pinboards are automatically migrated and saved as dashboards.

Currently, VCF Operations for networks doesn't support dashboard backup and restore features. So, you cannot take backup of the dashboard data and restore the data in a new deployment.

**Viewing All Dashboards**

To view all dashboards in VCF Operations for networks, on the navigation pane, click **Dashboard** > **All Dashboards**.

You can edit, delete, share, or duplicate dashboards based on the access granted.

**Note:**
If you are an admin user, the **All Dashboards** page displays two tabs:

- The **My Dashboards** tab displays all the dashboards created by other users accessing the VCF Operations for networks instance.
- The **Admin View** tab displays dashboards created by the administrator.

**Note:**
It takes some time for the dashboard to appear in the **All Dashboards** page after it is created.

## Create a Dashboard

In VCF Operations for networks, you create a dashboard to quickly access information that is critical to your business operations.

To create a dashboard, do one of the following:

- a. Click the **Create New Dashboard** option on the homepage or on the **All Dashboards** page.
  b. Enter the name and description for the new dashboard.
  c. From the **Suggested Widgets** section, drag widgets and drop them to the dashboard. Or, click the **Add** button on the widget to add the widget to the dashboard.
  d. Click **Save**.
- a. Click the pin icon on the widget that you want to pin.
  b. Click **Create New Dashboard** on the **Pin to Dashboard** pop-up window.
  c. Enter the name and description for the new dashboard.
  d. Click **Create and Pin**.

**Note:**

- The dashboard name must be unique across VCF Operations for networks.
- The dashboard name must not have more than 100 characters.
- You can use only letters, numbers, and spaces while naming a dashboard.
- The maximum number of entries you can see in the **Recently Modified** list is 15.
- The maximum number of dashboards that you can create across all users is 500. The maximum number includes custom dashboards, shared dashboards, and default dashboards.
- The maximum number of pins allowed per dashboard is 20.

You can perform the following actions on the dashboard:

- Share the dashboard with any other VCF Operations for networks users.
- Edit the name and description of the dashboard.
- You can modify, and rearrange the pins on a dashboard. Their positions are persisted.
- Duplicate and delete the dashboard.
- Export the information on the dashboard as a PDF report.

## Updating a Dashboard

You can add, delete, and organize widgets on the update dashboard page.

You can click the **Edit** button on the respective dashboard page to update the dashboard.

On the update dashboard page, you can:

- Update the dashboard name and description.
- Rearrange widgets in the dashboard by clicking the drag icon on the widget.
- Add new widgets to the dashboard.
- Delete existing widgets from the dashboard.

After updating the dashboard page, you can either click **Save** to save the latest changes, or click **Reset all** to reset the dashboard to the last saved state.

### Sharing a Dashboard

You can share the dashboards that you create with other users or groups (LADP/AD/vIDM). An admin user can view and delete any dashboard.

The following are the features of sharing and collaboration of dashboards:

If you have created a dashboard, you can view, edit, or delete it irrespective of you being an admin or a member user.

| Dashboard Owner | Shared With | Privilege | Possible Actions |
|---|---|---|---|
| Admin | Admin | View and Edit | View, Edit, Delete |
| | Admin | View only | View, Delete |
| | Member | View and Edit | View, Edit |
| | Member | View only | View |
| Member | Admin | View and Edit | View, Edit, Delete |
| | Admin | View only | View, Delete |
| | Member | View and Edit | View, Edit |
| | Member | View only | View |

**Note:**
The admin user can delete any dashboard.

To share a dashboard:

1. Click **More Options** on the dashboard that you want to share.
2. Click **Share**.

   **Note:**
   You can also share a dashboard from the **All Dashboards** page.
3. By default, the link sharing is enabled. You can share the link of a dashboard with any users or groups (LDAP/AD/vIDM).
4. You can add the users with whom you want to share the dashboard. You can specify the privileges such as `view` and `view and edit` to a particular user.

   **Note:**

   Users that only have view priviliges cannot share the dashboard with other users.
5. Click **Save** to save the share and collaboration changes that you have made.

You can view the sharing and collaboration information in the **Shared** column of the particular dashboard on the **All Dashboards** page.

## Manage Dashboards on the Home Page

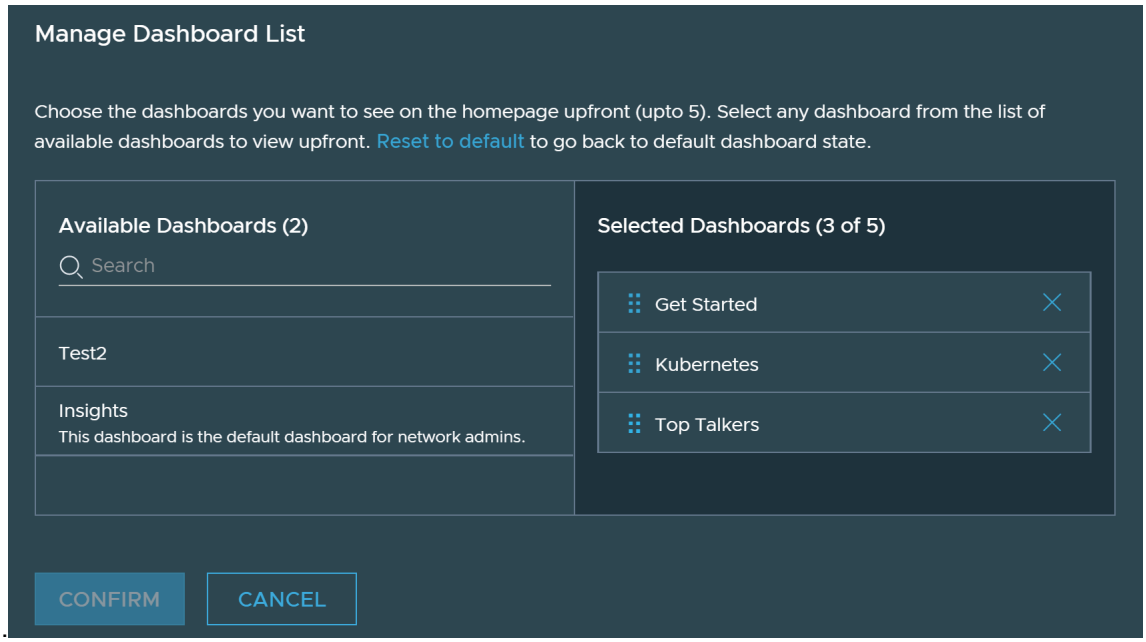
You can choose the dashboards you want to view on the homepage:

You must have created at least one dashboard in VCF Operations for networks.

1. Navigate to the homepage.
2. Click the **More** drop-down menu and select **Manage Dashboard List**.

   **Note:**
   The **More** drop-down menu is displayed only if you have created one or more dashboards in VCF Operations for networks.

   The **Manage Dashboard List** window is displayed.



3. On **Available Dashboards**, hover over a dashboard and click **>** to move the dashboard to **Selected Dashboards**.

   **Note:**
   You can display upto five dashboards on the homepage.

4. Optional: To rearrange the order of dashboards on the **Selected Dashboard** list, use the drag icon before the dashboard name.
5. Click **Confirm** to save changes.

   If you want to revert the changes and restore dashboards to their default state, click **Reset to default**.

## To Duplicate a Dashboard

1. From the left navigation pane, go to **Dashboards** > **All Dashboards**.

   A list of existing dashboards is displayed.
2. To duplicate a dashboard, click the **More Options** icon and select the **Delete** button.
3. On the pop-up window, enter the name and description of the new dashboard and click **Duplicate**.

   **Note:**
   The name of the dashboard is mandatory. The **Duplicate** button is deactivated till you enter the name.

4. If you are trying to duplicate a dashboard that is shared, then you can opt to retain the source dashboard users and their permissions. Select **Keep source dashboard users and permissions** if you want to retain them.

   **Note:**
   If the dashboard that you want to duplicate is shared with you with read-only access, you do not see the **Keep source dashboard users and permissions** option.

   The user who duplicates a dashboard becomes the owner of the new dashboard.

### Delete a Dashboard

1. From the left navigation pane, go to **Dashboards** > **All Dashboards**.
   A list of existing dashboards is displayed.
2. To delete a dashboard, click the **More Options** icon and select the **Delete** button.
3. On the **Confirm Action** pop-up window, click **Delete**.

   **Note:**
   You can delete a dashboard only if:

   - You created the dashboard.
   - You have edit access to the shared dashboard.

   You cannot delete a dashboard that is shared with you with read-only access.

## Working with Local Tags

VCF Operations for networks enables you to add custom local tags for supported data sources.

Local tags are always a key-value pair where you can add a unique key and a value. The local tags help you organize and find your data source faster and better. The local tags has the following characteristics:

- Tags are always key-value pairs.
- Keys must be unique with only one value.
- Tags are extended properties of entities.
- Tags are meant to be consumed with search.
- Tag key can be of maximum 63 characters and value can be of maximum 255 characters.
- Maximum 25 tags can be added per data source.
- Tags can be used only for plain text search.

You can add the local tags only in VCF Operations for networks. When you select **Apply tag operations to all associated entities** check box, the tags get applied to all associated entities related to that data source.

The following are the supported data sources and the associated entities for local tags:

| Data Source | Associated Entities |
|---|---|
| VMware vCenter | Host |
| VMware NSX-T | • NSXT Transport Node<br>• NSXT MP Node<br>• NVDS<br>• NSXT Router Device<br>• Virtual Host Switch<br>• Virtual Host Router |
| Cisco UCS Manager | • Blade servers<br>• Fex<br>• Fabric interconnect switches |
| ACI | Leaf and spine devices |
| Palo Alto Networks | • Pan Physical Device<br>• Pan VM Device |

| Data Source | Associated Entities |
|---|---|
| Checkpoint management server | Check point gateways |
| Cisco Nexus | N2K device |
| • Arista 7050QX-32S, 7280TR<br>• Cisco ASR 1K<br>• Cisco ISR 4K<br>• Cisco ASR 9K<br>• Cisco Catalyst 3000, 4500, 6500, 9300<br>• Dell OS10<br>• Force 10<br>• Juniper<br>• Mellanox<br>• All routers and switches with a single manager | L3 Switch |
| F5 BIG-IP | F5 Big IP |
| Cisco ASA | L3 Switch |

# Load Balancer Support in VCF Operations for networks

Load balancing allows you to distribute inbound application traffic across multiple back-end destinations, including deployments in public or private clouds. It is therefore a necessity to have the concept of a collection of back-end destinations.

In addition to the load balancing support, VCF Operations for networks also provides the following advantages:

- Enables to identify whether the application servers are physical servers or the virtual machines.
- Allows you to debug or troubleshoot the problems easily by providing visibility into the application server (host or VM) information such as configuration, performance, flows.
- Provides visibility into physical or virtual networking components in an application where the load is distributed.
- Raises alerts for any issue in the environment and also helps to detect the reason for the issue. For example, application is not responding because the service node VM is down.
- Provides end to end flow visibility.

  **Note:**
  VCF Operations for networks does not support end to end flow visibility in Avi Load Balancer. However, it supports the VM-VM path.

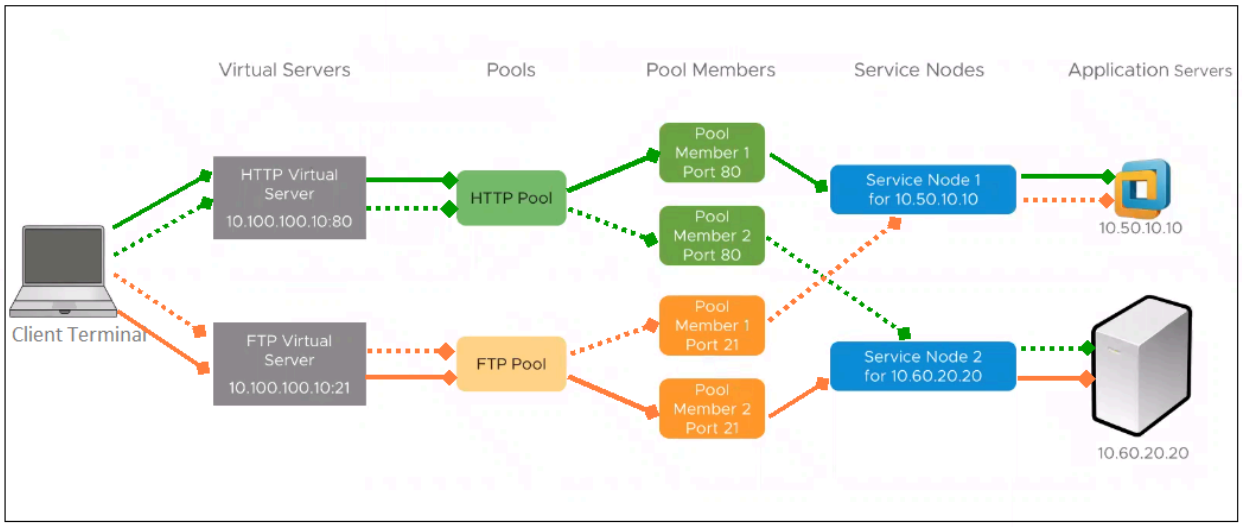
VCF Operations for networks supports the following load balancers:

- F5
- VMware Avi Load Balancer

## F5 as a Load Balancer

VCF Operations for networks supports the F5 load balancing feature by discovering and representing the required F5 components, such as service nodes, pool members, pools, and virtual servers.

### Overview of a F5 Load Balancer and its Components



- Application Servers - The machines where the applications are hosted. For example, if you have a web server, your server runs on application servers (physical or a virtual server).
- Service Nodes - F5 represents the application servers as service nodes. Service node have the same IP address or FQDN of the application server. Each service node can have multiple applications.
- Pool Members - A logical entity. Each application in a service node is represented by a pool member, which has the same IP address or FQDN of the service node. To identify different applications, the pool members embed the port number with the IP address of the Service Nodes.
- Pools - All pool members that serve one application are grouped as a pool.
- Virtual Servers - A public facing IP address of the application. Clients that want to use an application connect to the virtual server IP address (For example, 10.100.100.10) and port number (80 or 21).
- Client Terminal - The connection starts from a client terminal, such as a desktop, laptop, mobile device, or virtual machine.

The client request connects to the virtual server, which decides the pool members based on the pool. Pool members, then, forward the request to the application server (VM or physical server).

> **Note:**
> A single application server can serve multiple requests from different ports and different service nodes.

## Overview of VMware Avi Load Balancer

Avi Load Balancer performs load balancing and delivers application services such as application analytics, predictive autoscaling, and micro-segmentation.

### Platform Overview

The Avi Load Balancer platform includes the following components:

- Controller cluster. A single point of management and control of the Avi Load Balancer system. It is usually deployed as a redundant three-node cluster and has full visibility across the environments. It automates the deployment and management of the service engines.
- Service engine. Receives and executes instructions from the Controller. The Service engines perform load balancing and manages client and server-facing network interactions.
- Virtual service. Advertises an IP address and ports to the external world and listens for client traffic.

### Supported Load Balancers

Avi Load Balancer supports the following load balancers:

- Native Load Balancer, also referred to as L2 Load balancer

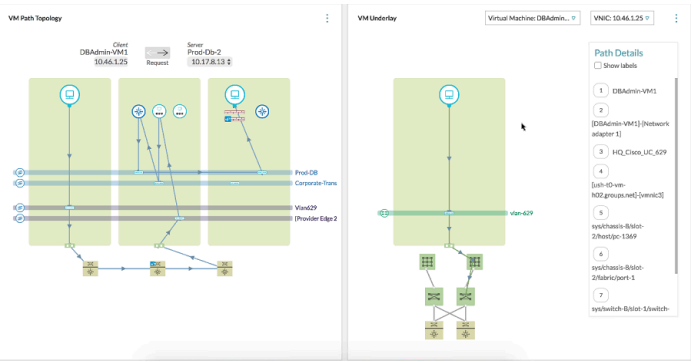
- Equal-Cost Multi-Path (ECMP) Load Balancer

In Avi Load Balancer, virtual services can be scaled across one or more service engines using either native (L2 punting) or BGP-based load balancing techniques. Virtual services in a Native Load Balancer can be scaled upto four service engines. Virtual services in an ECMP Load Balancer can be scaled upto sixty four service engines.

# Network Visibility

## Path Topology

The path topology draws a detailed connection that exists between any two virtual machines in your environment.



The topology involves both Layer 3 and Layer 2 components. You can view this topology using the search query `vm_name_1` to `vm_name_2`. If a path exists, the VM-to-VM path visualization proceeds to populate all the components that exist between `vm_name_1` to `vm_name_2` and also draws an animated path. If the routers are physical, then they are shown outside the boundary. To see physical routers, you must enable Link Layer Discovery Protocol (LLDP) and, if it is supported, Cisco Discovery Protocol (CDP) on the network devices.

In the path topology, you see the VM-to-VM path between the source and the destination. If the default path is not configured between the VMs, an error message appears to inform that the path is not defined or the router interface is not found.

For Kubernetes, the Path topology displays the path for the following scenarios:

- Kubernetes Service to Kubernetes Service
- Kubernetes Service to Kubernetes Pod
- Kubernetes Pod to Kubernete Pod

> **Note:**
> The path involving physical devices is not supported.

The **Path Via Load Balancer** option lists all the load balancers that are used in between the path from the selected source and the destination VM. To see the path between the VMs via a particular load balancer, select the load balancer name from the list. If you hover the mouse on load balancer component on the path topology, you see the following details:

- Virtual Server name
- Load Balancer IP address
- Port number
- Load Balancer Algorithm
- The default gateway that was taken from the load balancer.

You can also see the routing components on the path topology.

If you hover your mouse on any of the routers, edges, or LDRs that are involved in the path, the complete routing or NAT information is shown.

The VM Underlay section that is on the right side of the VM Path topology shows the underlay information of the VMs involved and their connectivity to the top of the rack switches and the ports involved. For Kubernetes entities, VM Underlay displays the VM or the Kubernetes node information on which the Pod resides.

In the VM underlay section, the components are labeled if you select **Show labels** under **Path Details.** In this section, the drop-down list at the top shows the endpoint VMs and the active VMs at the edges. For each edge VM, the neighboring drop-down menu shows the ingress and the egress interface IP addresses. Based on the selection, the underlay path for that particular interface is shown.

You can also reverse the path direction using the arrows on top of the topology map.

The topology map gives more visibility regarding the ports involved in the VM-VM path. In the **Path Details** section, the name of the actual port channel is shown.

For NSX-T version 4.x and later, VCF Operations for networks does no support VM-VM path for federation deployments.

**Note:**
There is no complete visibility for layer 2 on the physical front. If a packet is traversing from one switch to another, there maybe multiple switches involved. But the topology does not show the switches in the underlay network.

## AWS VM-VM Path

The VM-VM path for AWS provides the path visibility between the on-premises VMs and the AWS EC2 instances.

Currently, VCF Operations for networks supports the following scenarios:

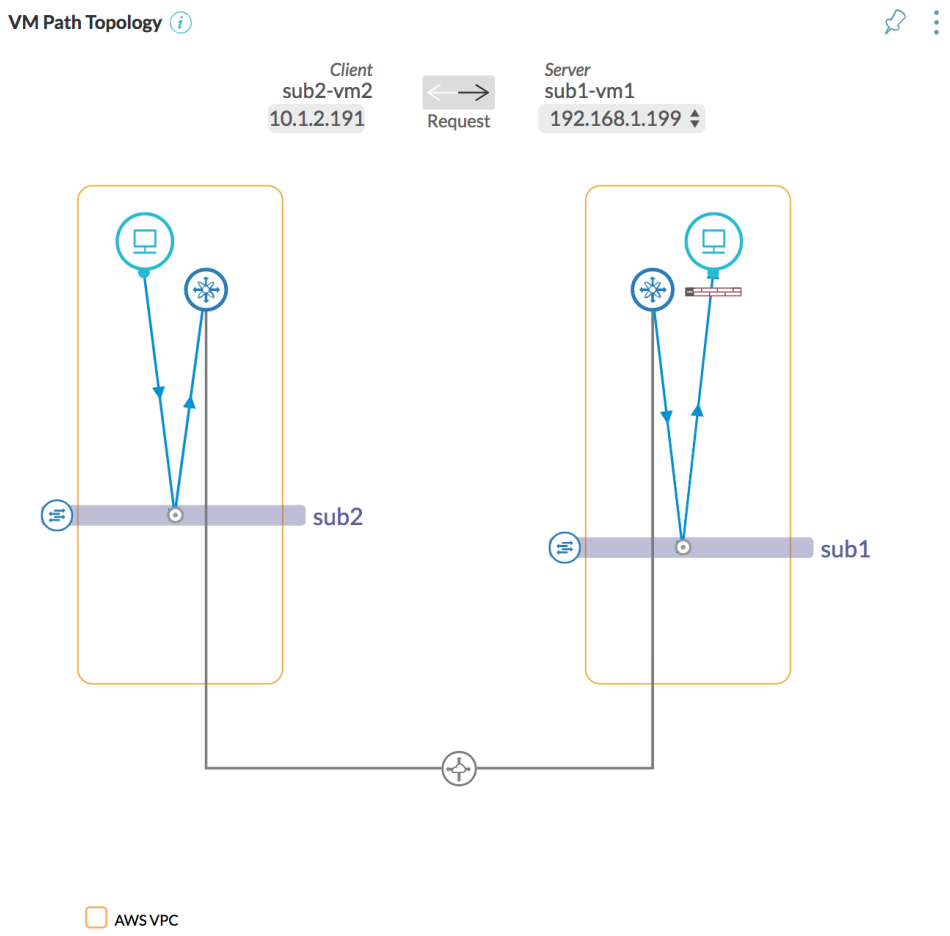
- AWS intra-VPC VM-VM path: This scenario involves the communication between the VMs of the same subnet or different subnets in a particular VPC.
- AWS inter-VPC VM-VM path through the peering connection: This scenario involves the communication between the VM of one VPC to the VM of another VPC through a peering connection.
- AWS VM to Internet: The VM in a VPC communicates to Internet through the Internet Gateway.
- AWS VM to the data center VM through AWS VPN connection: In this scenario, the VM in a VPC communicates to the VM in a data center through the AWS VPN connection. VCF Operations for networks supports SDDC and NSX-T data centers for this scenario.

  **Note:**

  - The hybrid path topology to NSX-T data centers works only when the NSX-T edge routers are configured with a public IP address.
  - VCF Operations for networks does not support the VM underlay topology for AWS.

  **Note:**

An example of the AWS VM-VM path for the AWS inter-VPC VM-VM path through the peering connection is as follows:



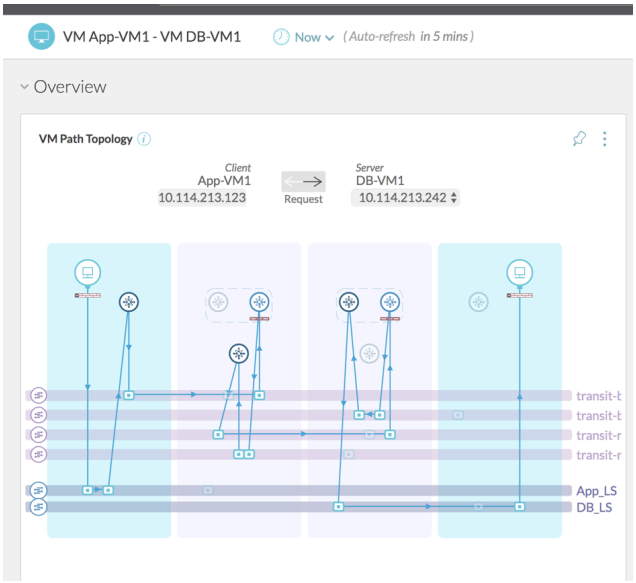
You can view the properties of the peering connection by pointing to its icon in the VM-VM path.

You can search the following entities concerning the AWS VM-VM path:

- AWS Subnet
- AWS Route Table
- AWS Virtual Private Gateway
- AWS Internet Gateway
- AWS VPN Connection
- AWS VPC Peering Connection

## NSX-T VM-VM Path

An example for VM-VM path for NSX-T is as follows:



The blue color represents the host node and the grey color represents the edge node. The icons used in the VM path topology are listed on the right side of the screen along with the labels under Path Details. The distributed routers are shown in the same color irrespective of their tiers. The color of the service router in the topology diagram changes as per the associated tier. All the Tier 1 components are shown at the same level and all the Tier 0 components are shown at a different level. In NSX-T, the edge firewalls are depicted in the diagram.

## VCF Operation HCX VM-VM Path

In VCF Operations for networks, you can view the VM-VM path over a network extended by VCF Operation HCX Network Extension (HCX-NE) service.

VCF Operations for networks supports the following VM-VM path scenarios for VCF Operation HCX Network Extension:

Here are a few examples of VCF Operation HCX VM-VM paths:

### Single Site Network Extension (NE) Scenarios

- The source VM is on a local site and the destination VM is on a remote site. The VCF Operation HCX L2E extends the L2 network of the source VM to the remote site, and the destination VM is on that same extended L2 network on the remote site. So, logically, both the VMs are on the same L2 network.
- The source VM is on a different L2 network on a local site and the VCF Operation HCX L2E extends to a different L2 network from a local site to a remote site. And the destination VM is on this extended L2 network on a remote site. So, logically, the source VM and destination VM are on different L2 network.
- The source and the destination VMs are on a remote site, but both the VMs are on different extended L2 networks extended from the local site to the remote site.
- Both the source VM and the destination VM are on a remote site, and the source VM is on an extended L2 network but the destination VM is on a non-extended L2 network native to the remote site. Also, there is a different L3 connectivity between these sites.
- Path to internet via NE: The VCF Operation HCX L2E extends a L2 network from a local site to a remote and the source VM is on this extended L2 network on the remote site. The source VM is communicating to the internet.

**Figure 443: The source and the destination VM on different sites.**

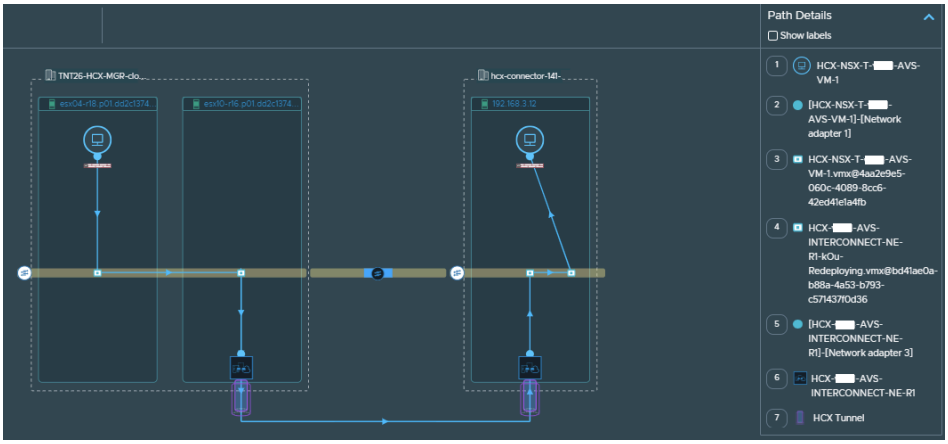


**Figure 444: The source and the destination VM on different remote sites**

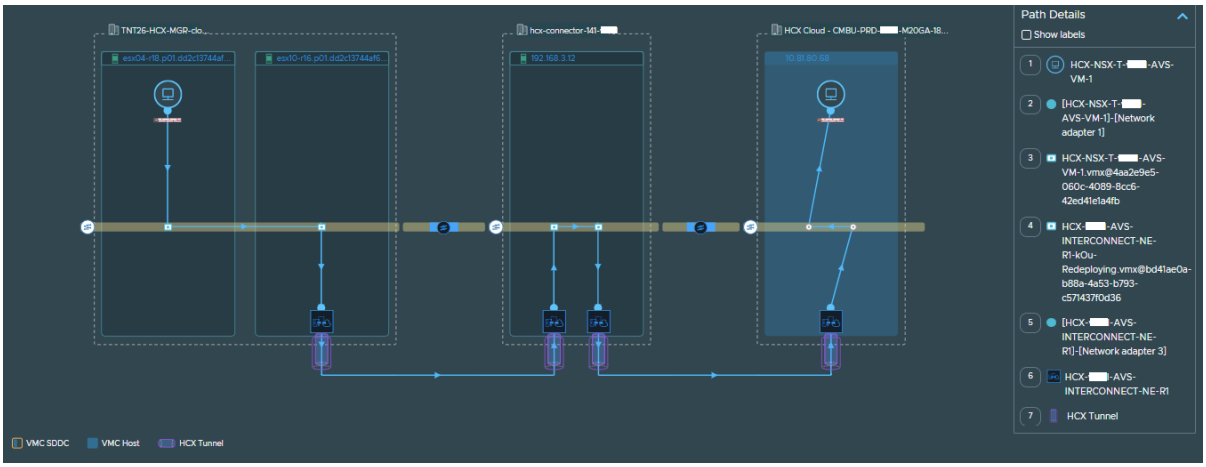

**Figure 445: VMs communicating to the Internet over the VCF Operation HCX Network Extension**

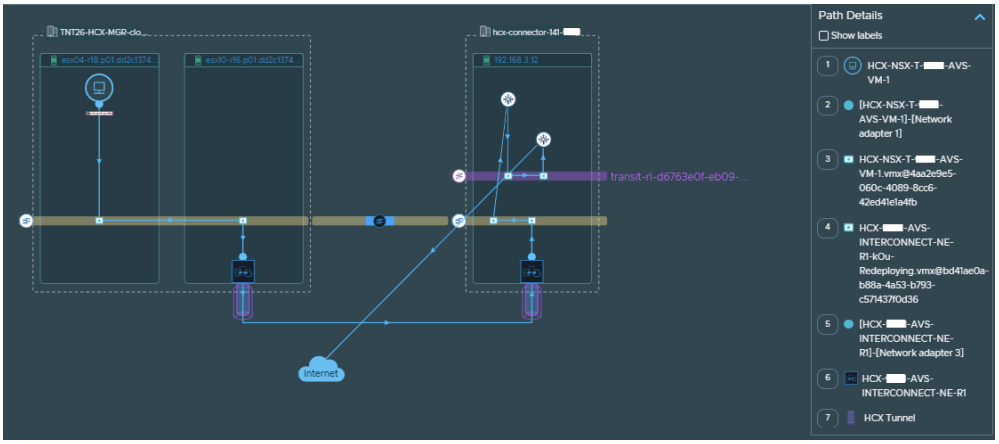

## Multi-site Network Extension (NE) Scenarios

V (One to Many) Network Extension: In this topology, the local site is paired to two remote sites, and a L2 network is extended to the two connected remote sites.

- In this scenario, the source VMs and the destination VMs are on the different remote sites on this same extended L2 network. So,logically, the VMs are on same L2 network.
- In this scenario, different L2 networks are extended to each of the connected remote sites. The source VM is on one remote site on the extended L2 network and destination VM is on another remote site on the extended L2 network. Logically, the VMs are on different L2 networks.

Daisy Chain Network Extension: In this topology, a local site is paired to a remote site and this remote site is paired to another remote site.

- A L2 network is extended to the first remote site and the same L2 network is extended to the next remote site. Source VM is on local site and Destination VM is on the second remote site. Logically, the VMs are on same L2 network.

### Unsupported Paths

Currently, we don not support the following VM-VM paths for VCF Operation HCX:

- Underlay paths
- Path with an endpoint as VCF Operation HCX Network Extension (HCX-NE) appliance.

## Support for NAT in VCF Operations for networks

VCF Operations for networks supports the VM-VM Path for NSX for vSphere, NSX-T Edges, Fortinet, and Check Point.

### VM-VM Path

A sample VM-VM path through NAT is as follows:

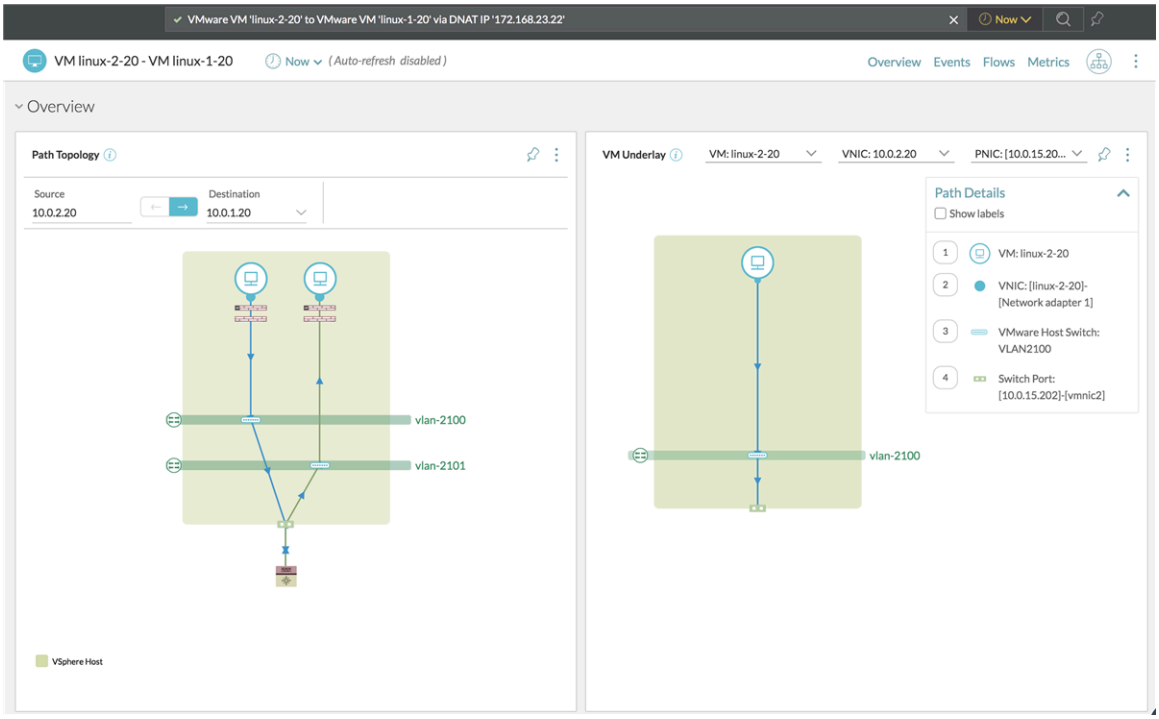

**Figure 446: VM-VM path through Check Point NAT**

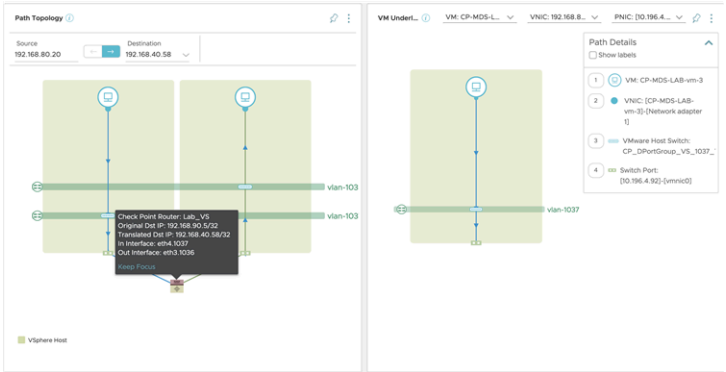


**Queries**

To view VM-VM path through NAT, use the following queries:

- If destination VM is behind a Fortinet and Check Point router, and configured with NAT, then use `VMware VM '<name of the VM>' to VMware VM '<name of the VM>' via DNAT` query.
- If destination VM is behind an NSX for vSphere or NSX-T Edge and configured with NAT, then use `VMware VM '<name of the VM>' to VMware VM '<name of the VM>'` query.

**Considerations**

- For the VM-VM path with the NSX-T logical routers where the NAT service is enabled, VCF Operations for networks doesn't show the NSX-T edge firewall rules correctly for such a path.

## Arista Hardware VTEP VM-VM Path

In VCF Operations for networks, you can view a hardware VTEP in the VM-VM path.

Currently, VCF Operations for networks supports the following scenarios:

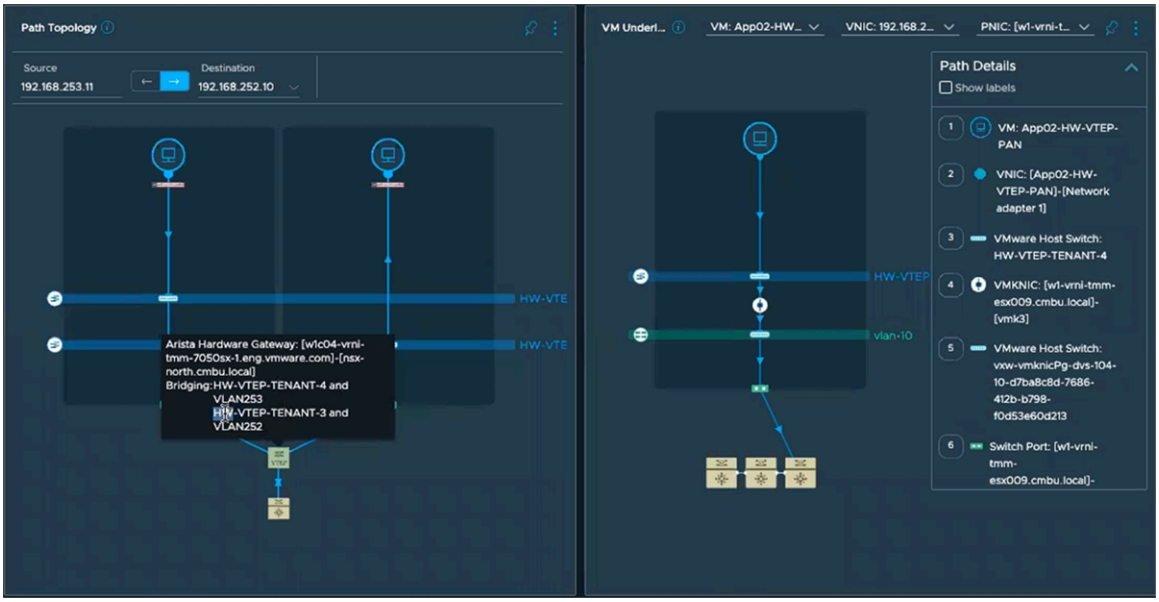
- VM-VM path through hardware VTEP when the source and the destination VMs are located in a different VXLAN and a different host.
- VM-VM path through hardware VTEP when the source and the destination VMs are located in the same host but different VXLAN.
- Hardware VTEP in the VM underlay topology when the switch is directly connected to the host.

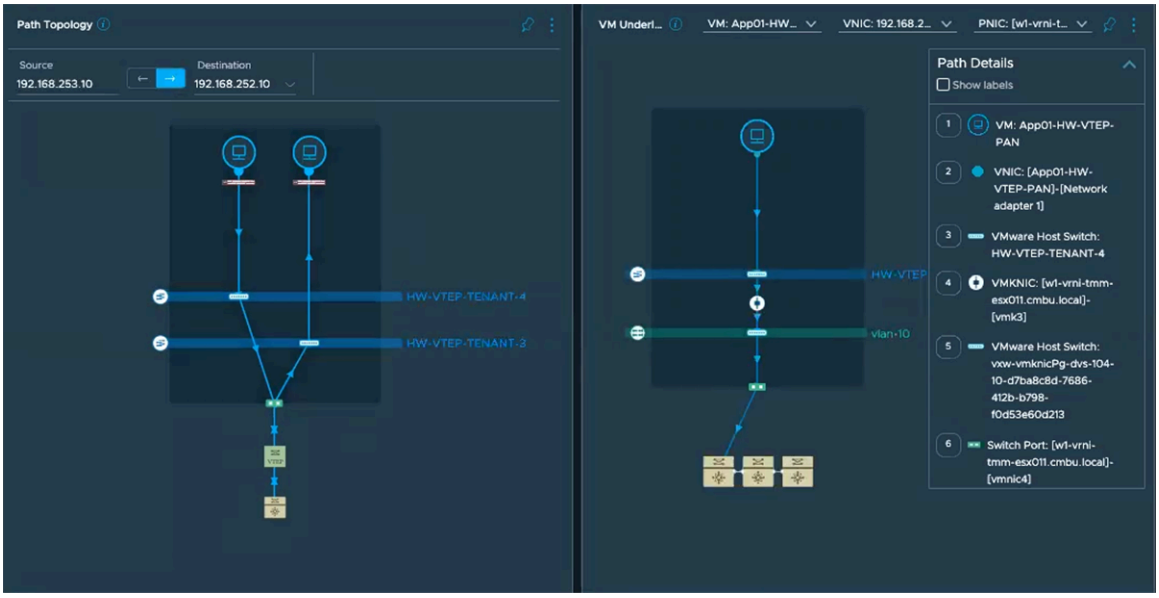
> **Note:**
> When you add the Arista Switch SSH in VCF Operations for networks as a data source, you must use the same IP/FQDN that you have used in the VMware NSX Manager to configure Arista Switch SSH. Otherwise, you do not see the hardware VTEP in the VM-VM path.

You can also view the hardware VTEP in VM topology and in the VM to Internet path if a hardware VTEP is available between the VM and Internet.

VM-VM path through the hardware VTEP when the source and destination VMs are located in the same VXLAN is unsupported.

Here are a few examples of VM-VM path through hardware VTEP:

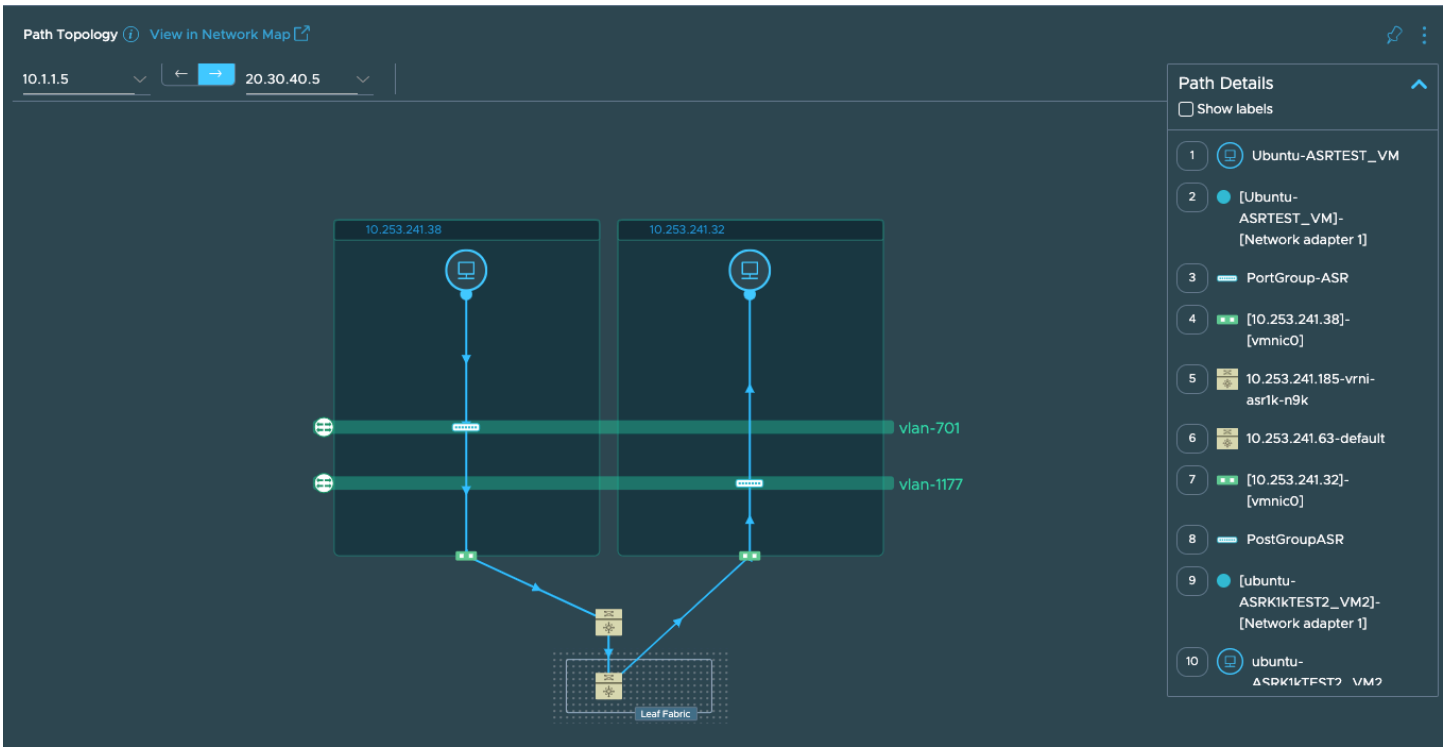




## Cisco ASR 1000 VM-VM Path

In VCF Operations for networks, you can view the VM-VM path through a Cisco ASR 1000.

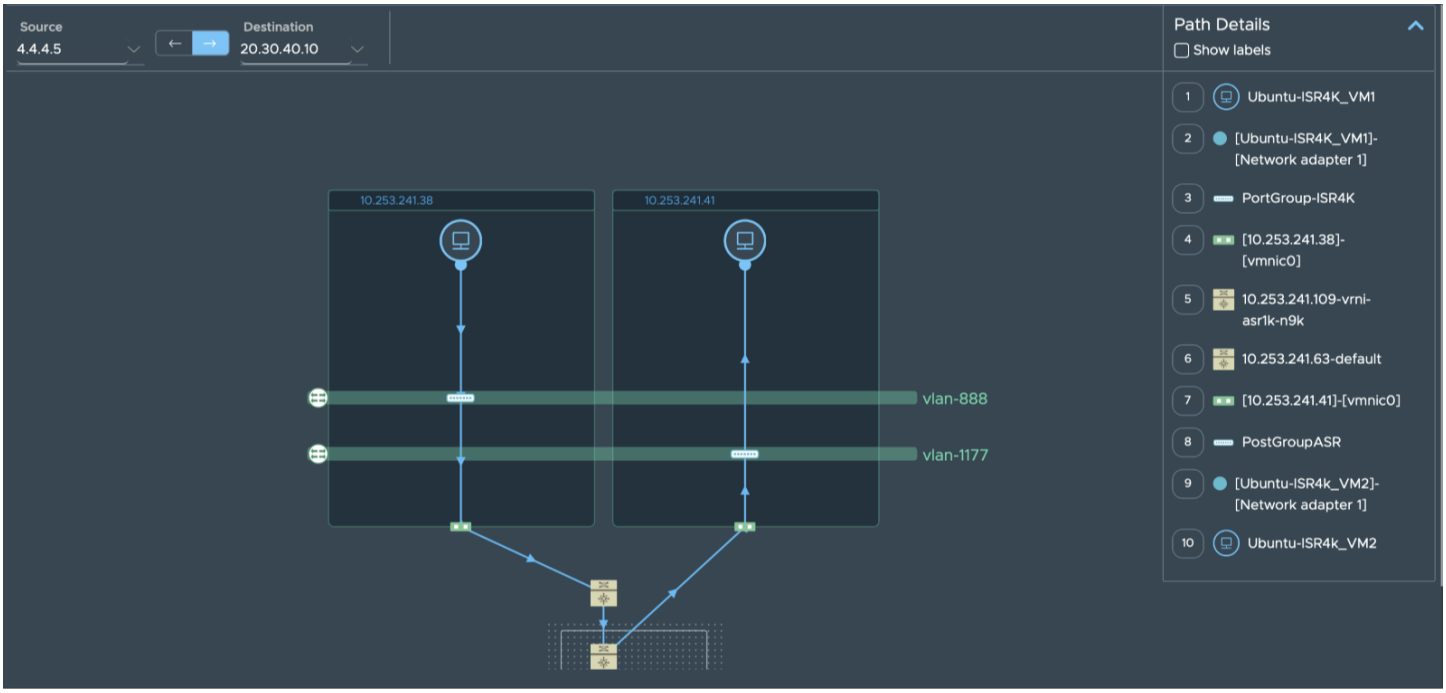
A sample VM-VM path for the Cisco ASR 1000 is as follows:



## Cisco ISR 4000 VM-VM Path

In VCF Operations for networks, you can view the VM-VM path through Cisco ISR 4000.

A sample VM-VM path for the Cisco ISR 4000 is as follows:



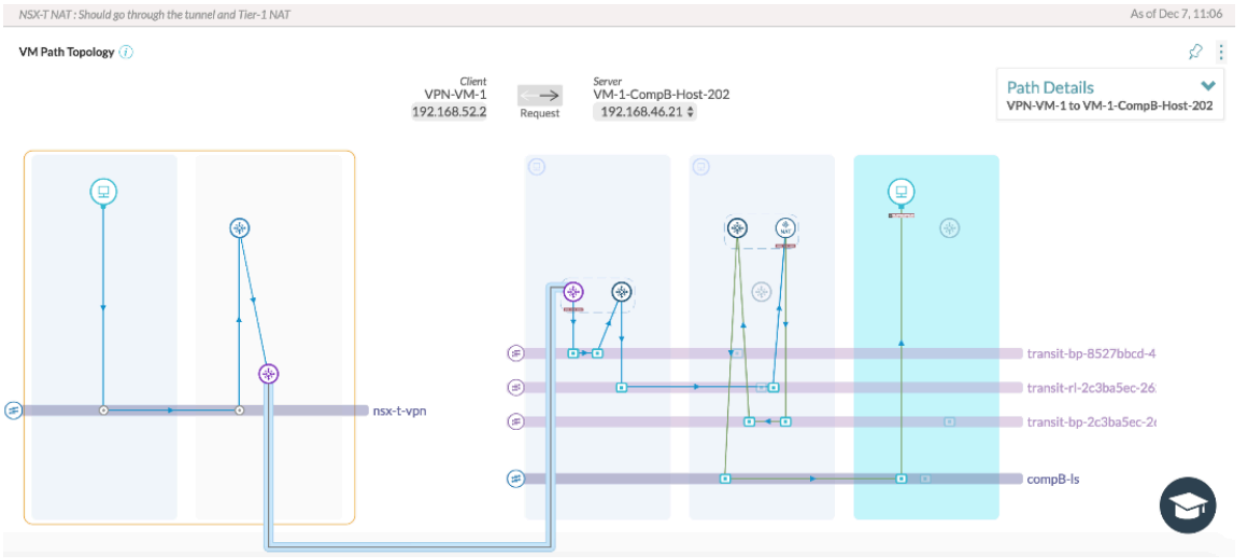
## VMware Cloud (VMC) VM-VM Path

VCF Operations for networks supports the following hybrid paths in VMware Cloud on AWS:

- VMware Cloud on AWS and VMware Cloud on AWS
- VMware Cloud on AWS and NSX-T
- VMware Cloud on AWS and AWS
- Intra VMware Cloud on AWS

For all VMs present in VMware Cloud on AWS, the underlay information is shown only until the segment on which the VM lies because the underlying physical elements of the network are abstracted out by VMware Cloud on AWS and no visibility is present at that level.

A sample VMware Cloud on AWS and NSX-T VM-VM path is as follows:



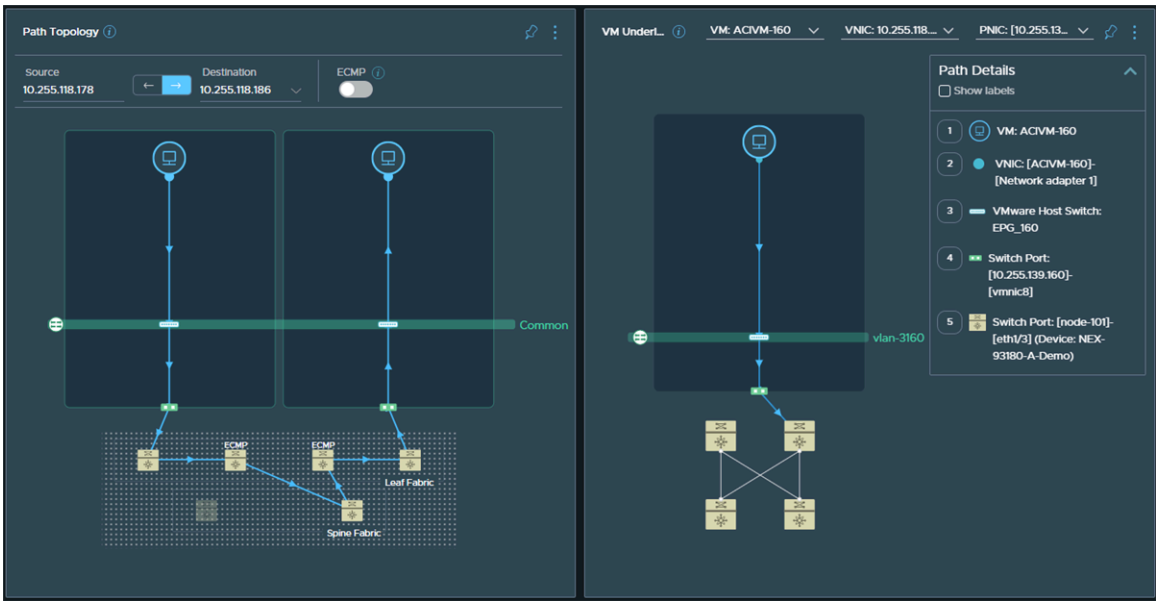
The dark blue line depicts the tunnel.

## Cisco ACI VM-VM Path

In VCF Operations for networks, you can view the VM-VM path through Cisco ACI.

A sample VM-VM path for the Cisco ACI is as follows:

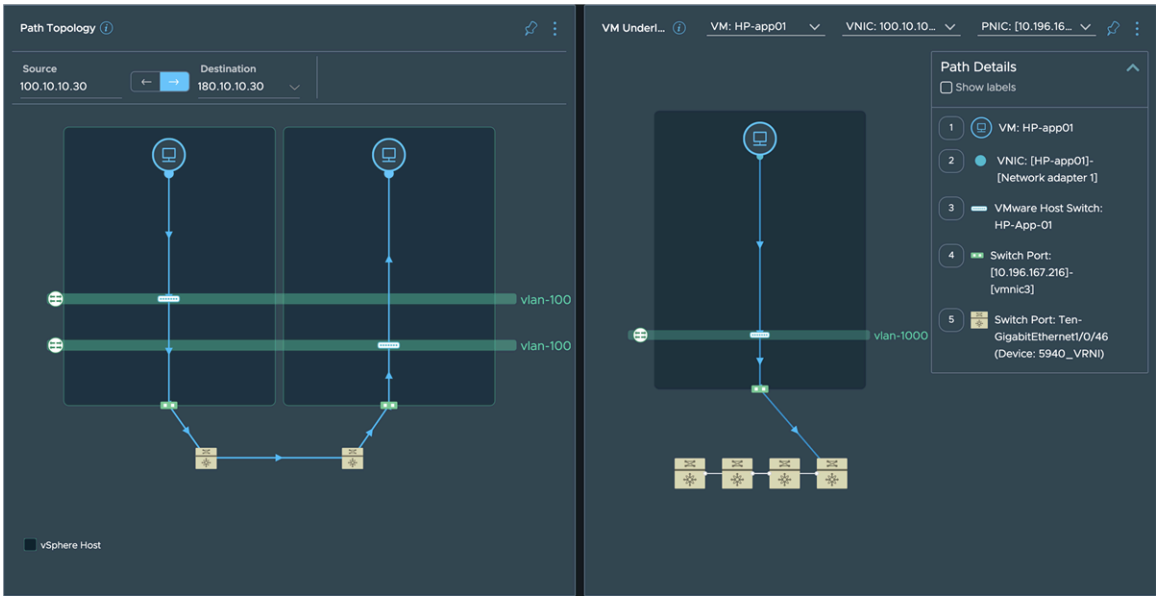
> **Note:**
> VCF Operations for networks shows the VM-VM path through the leaf and spine switches if the Cisco ACI APIs provide the switch level details. If not, VCF Operations for networks shows a single Cisco ACI VRF for the entire fabric instead of the leaf and spine switches in the VM to VM path.



## HPE VM-VM Path

In VCF Operations for networks, you can view the VM-VM path through supported HPE switches.

A sample VM-VM path through an HPE switch is as follows:



## Avi Load Balancer VM-VM Path

The VM-VM path provides the path visibility between the Avi Load Balancer Virtual Services in your environment.

Before viewing the path topology, learn about the core components of the Avi Load Balancer platform. For more information, see the Overview of VMware Avi Load Balancer topic.

**Note:**

VCF Operations for networks does not support vNIC - vNIC path in Avi Load Balancer.

NSX or VMware vCenter manages the network of Avi Load Balancer pool members. Therefore, you can view the following VM-VM paths only:

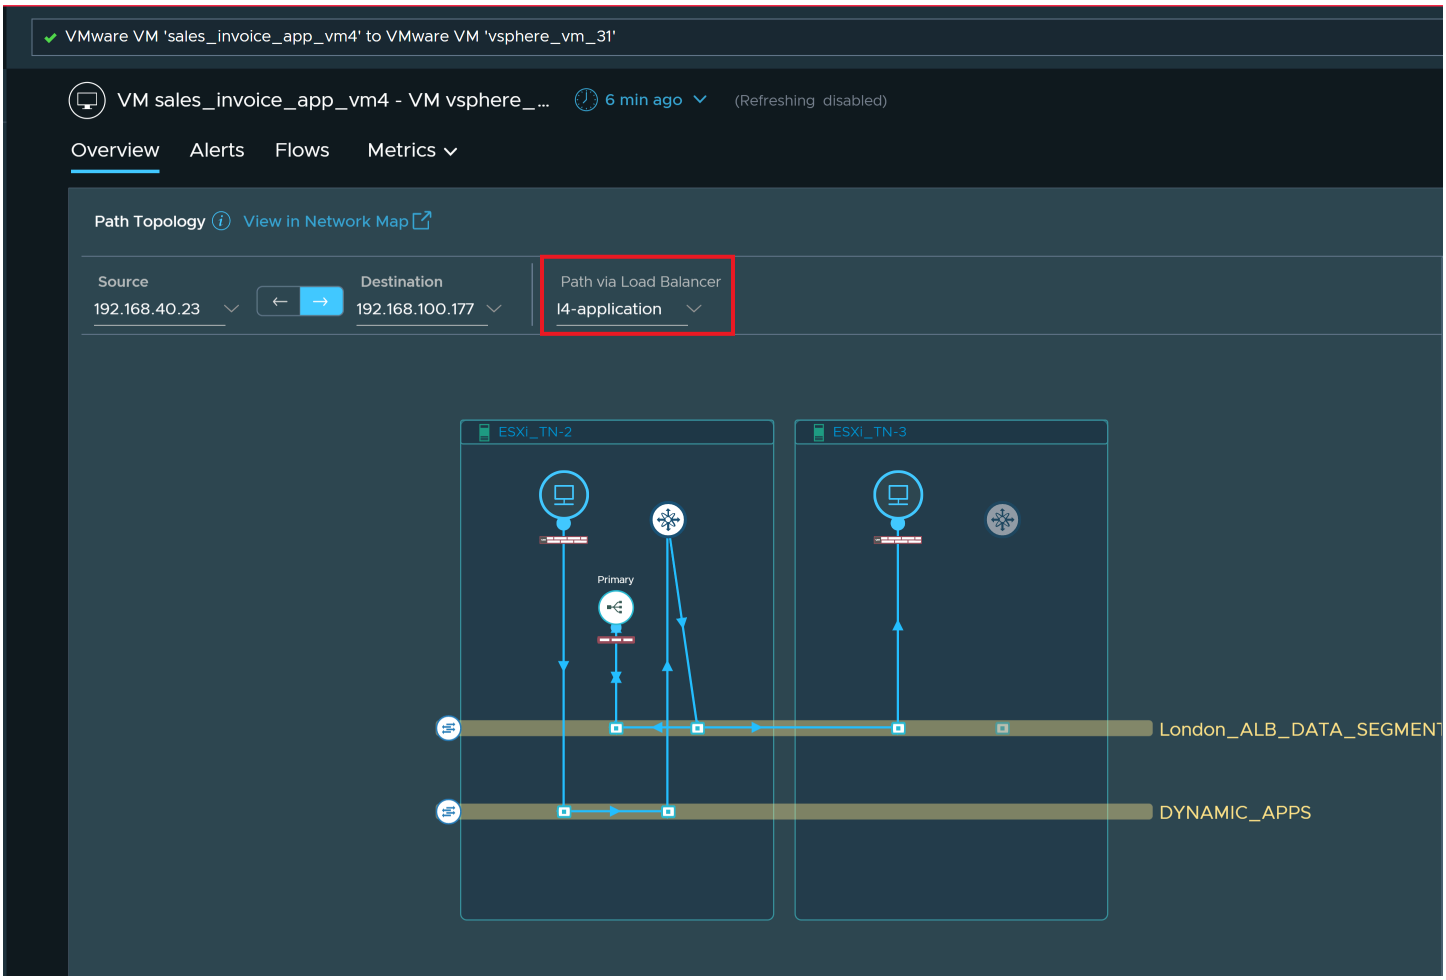
- NSX and Avi Load Balancer and VMware vCenter
- vCenter and Avi Load Balancer
- VMware Cloud on AWS NSX-T and VMware vCenter and Avi Load Balancer

### VM-VM Path Through a Virtual Service

To see the VM-VM path through a virtual service, perform the following steps on the Path Topology page:

1. Select the **Source** and **Destination** VMs.
2. Select the Avi Load Balancer virtual service from the **Path via Load Balancer** drop-down menu.

An example of VM-VM path through an Avi Load Balancer virtual service is as follows:



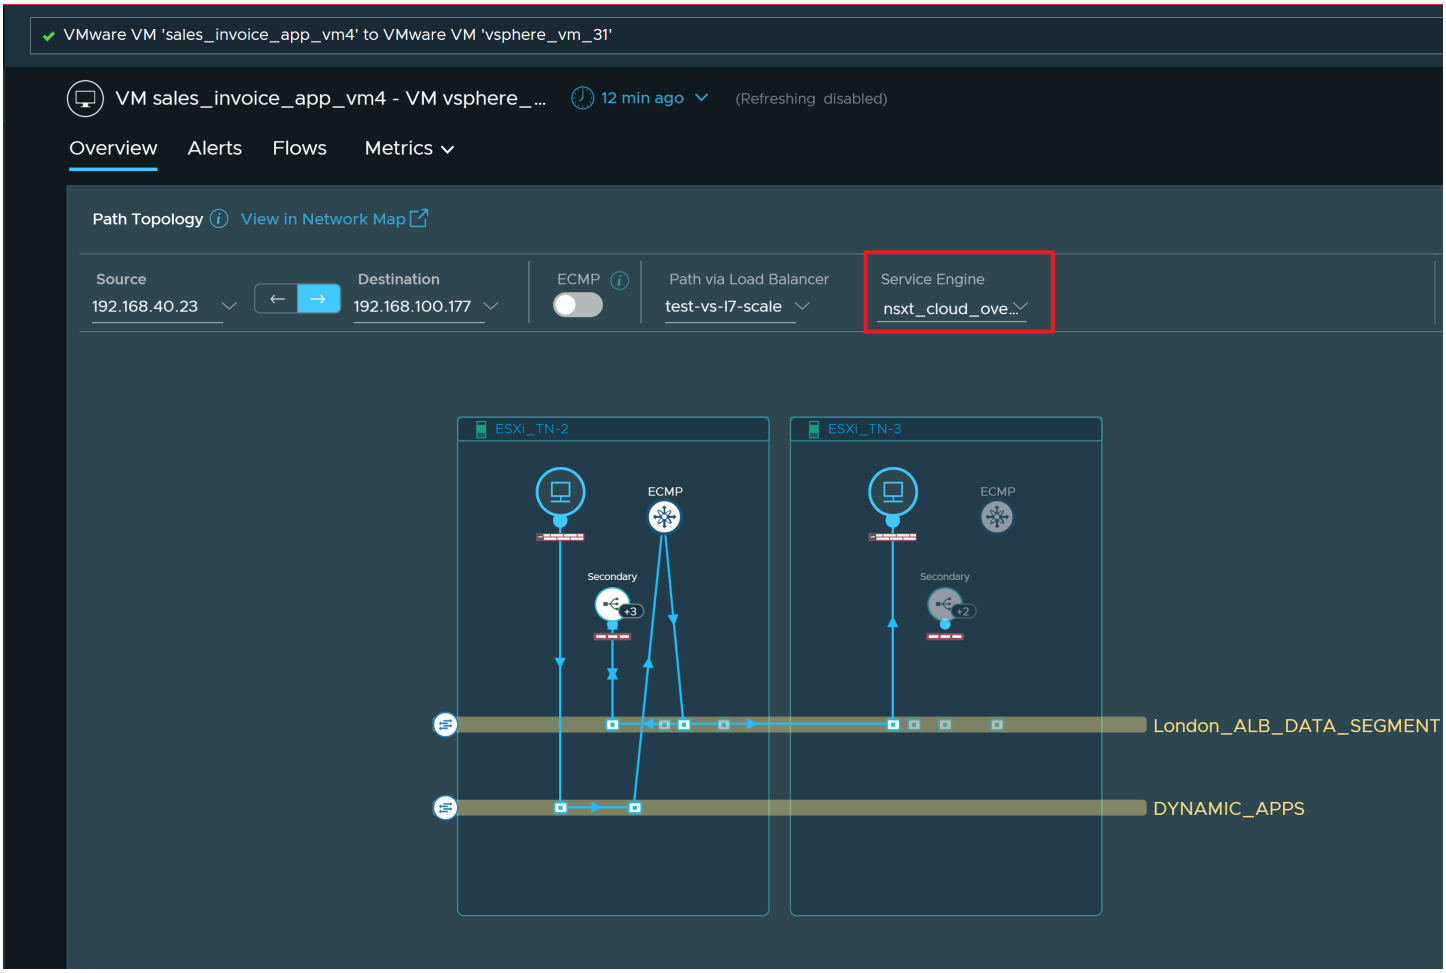
## VM-VM Path Through a Virtual Service That Uses Multiple Service Engines

When a virtual service is scaled across multiple service engines, by default, VCF Operations for networks displays the VM-VM path through the primary service engine.

To see the VM-VM path through a secondary service engine, perform the following steps:

1. Select the **Source** and **Destination** VMs.
2. Select the Avi Load Balancer virtual service from the **Path via Load Balancer** drop-down menu.
3. Select the secondary service engine from the **Service Engine** drop-down menu.

An example of the VM-VM path through a secondary service engine is as follows:



In this example, **+3** indicates that the traffic of the virtual service in ESX_TN-2 is distributed to three service engines, and **+2** indicates that the traffic of the virtual service in ESX_TN-3 is distributed to two service engines.

You can click the number on respective hosts to see the list of service engines associated with that host. You can also select a different service engine from the list to see the VM-VM path through the selected service engine.

> **Note:**
> To see the VM-VM path through all the Service Engines, turn on the **ECMP** toggle. For more information, see Support for Equal-Cost Multi-Path (ECMP) Route.

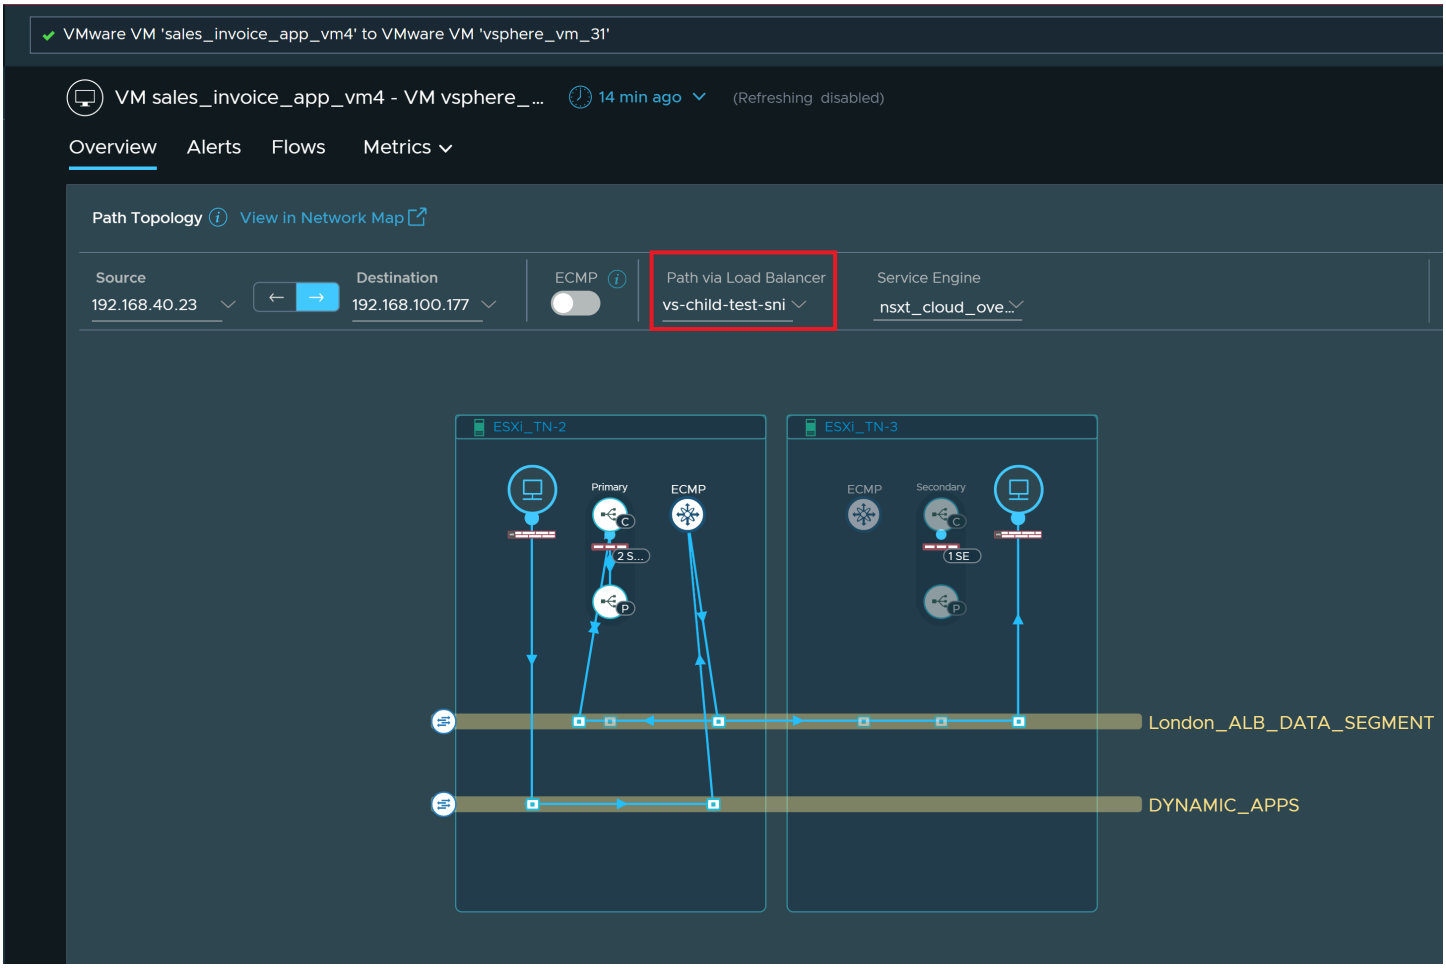
## VM-VM Path Through a Virtual Service That Uses Server Name Indication

Server Name Indication (SNI) is a method of virtual hosting multiple domain names for a single virtual IP.

In Avi Load Balancer, SNI hosting is implemented as parent and child virtual services. For more information, see the VMware Avi Load Balancer documentation.

If you have configured your virtual service to use SNI, select the child virtual service (through which you want to view the VM-VM path) from the **Path via Load Balancer** drop-down menu.

An example of a VM-VM path through a child virtual service is as follows:

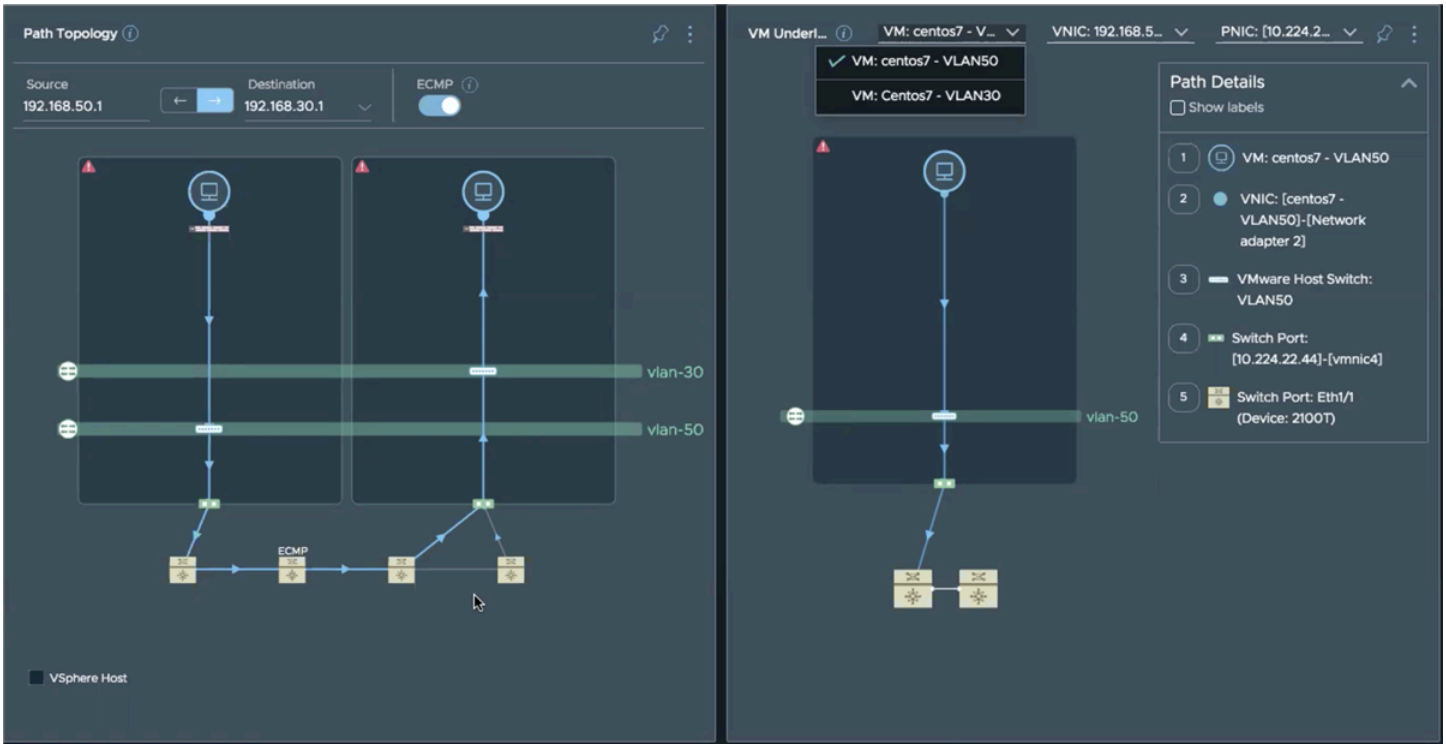


In this example, **2SE** indicates that the traffic of the virtual service in ESX_TN-2 is distributed to two service engines, and **1SE** indicates that the traffic of the virtual service in ESX_TN-3 is handled by a single service engine. You can click **SE** on respective hosts to see the list of service engines associated with the host. You can also select a different service engine from the list to view the VM-VM path through the selected service engine.

## Mellanox VM-VM Path

In VCF Operations for networks, you can view the VM-VM path through supported Mellanox switches.

A sample VM-VM path through a Mellanox switch is as follows:

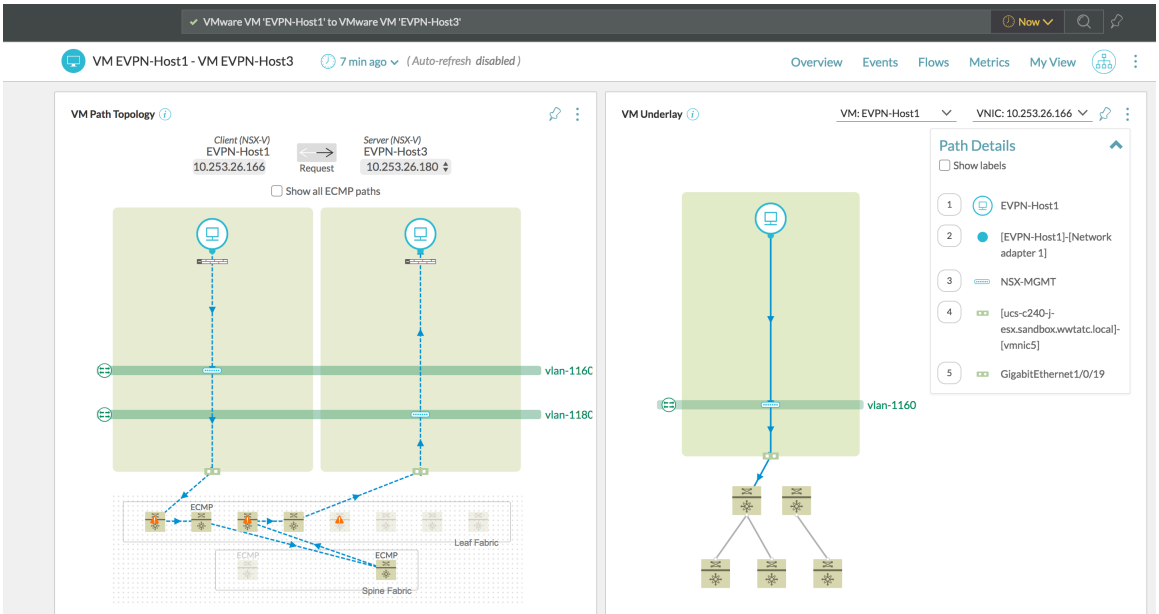


## Support for the Cisco BGP-EVPN Mode

VCF Operations for networks supports the fabric of Cisco 9000 switches configured in the Cisco BGP-EVPN configuration mode for the Enterprise edition only. VCF Operations for networks does not support the switch models other than Cisco Nexus 9000 with the Cisco BGP-EVPN configuration.

Each Cisco Nexus 9000 switch that is a part of the fabric is individually added as a data source. To view all the spine or leaf switches in the fabric, use the `switches where role is set` query.

A sample VM-VM path for the Cisco BGP-EVPN mode is as follows:



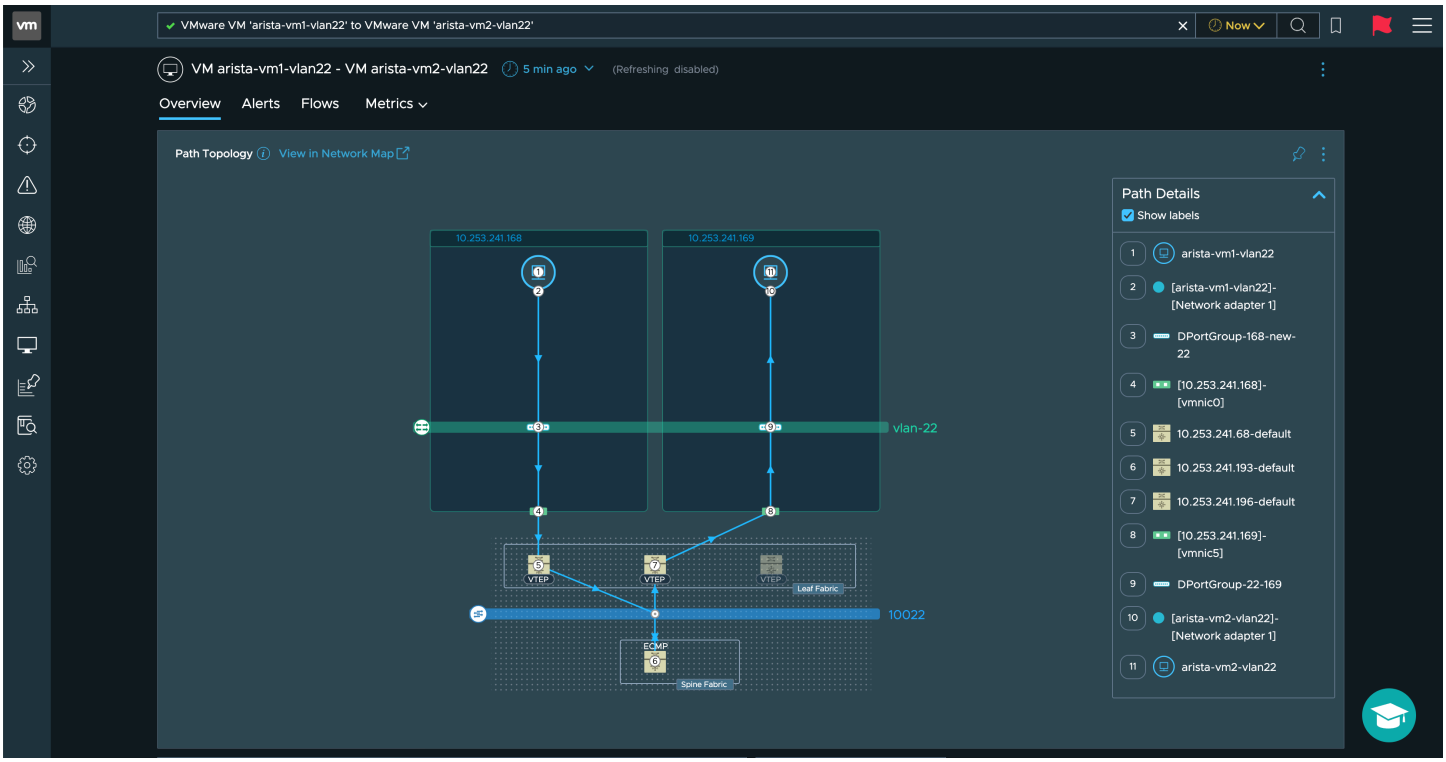
## Support for Arista BGP EVPN

VCF Operations for networks supports Arista Layer 2 and Layer 3 Ethernet VPN (EVPN) in the asymmetric Integrated Routing and Bridging (IRB) mode.

In the asymmetric IRB mode, EVPN allows the routing operation to occur closer to the end host by integrating the routing and bridging functionality directly onto the VXLAN Tunnel Endpoint (VTEP).

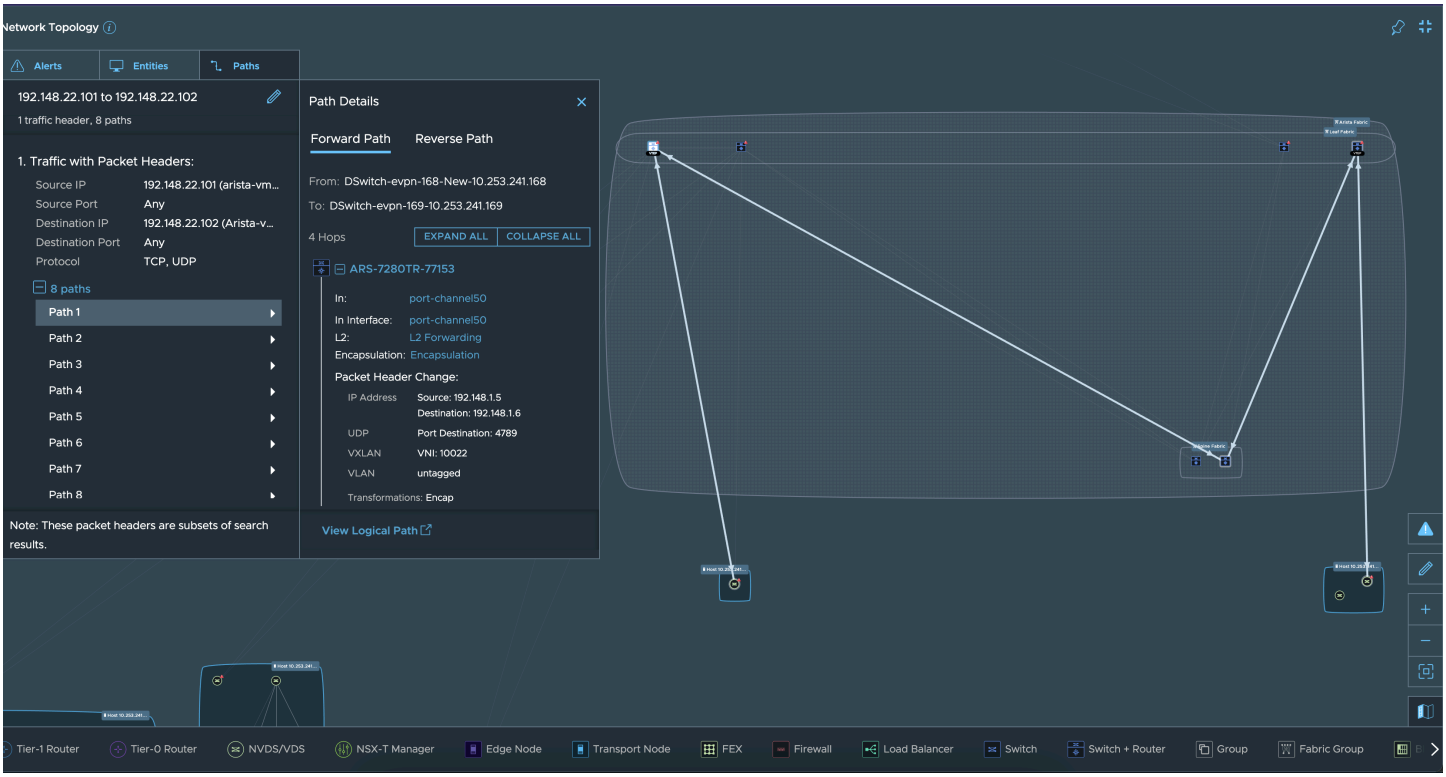
When you view the VM-VM path for Arista switches, VCF Operations for networks also displays the spine and leaf switches of the Arista fabric. Where, the leaf switches are responsible for encapsulation and decapsulation of data packets, and the spine switches are responsible for the BGP routing.

A sample VM-VM path of Arista BGP EVPN (same VLAN) with spine and leaf fabrics is as follows:

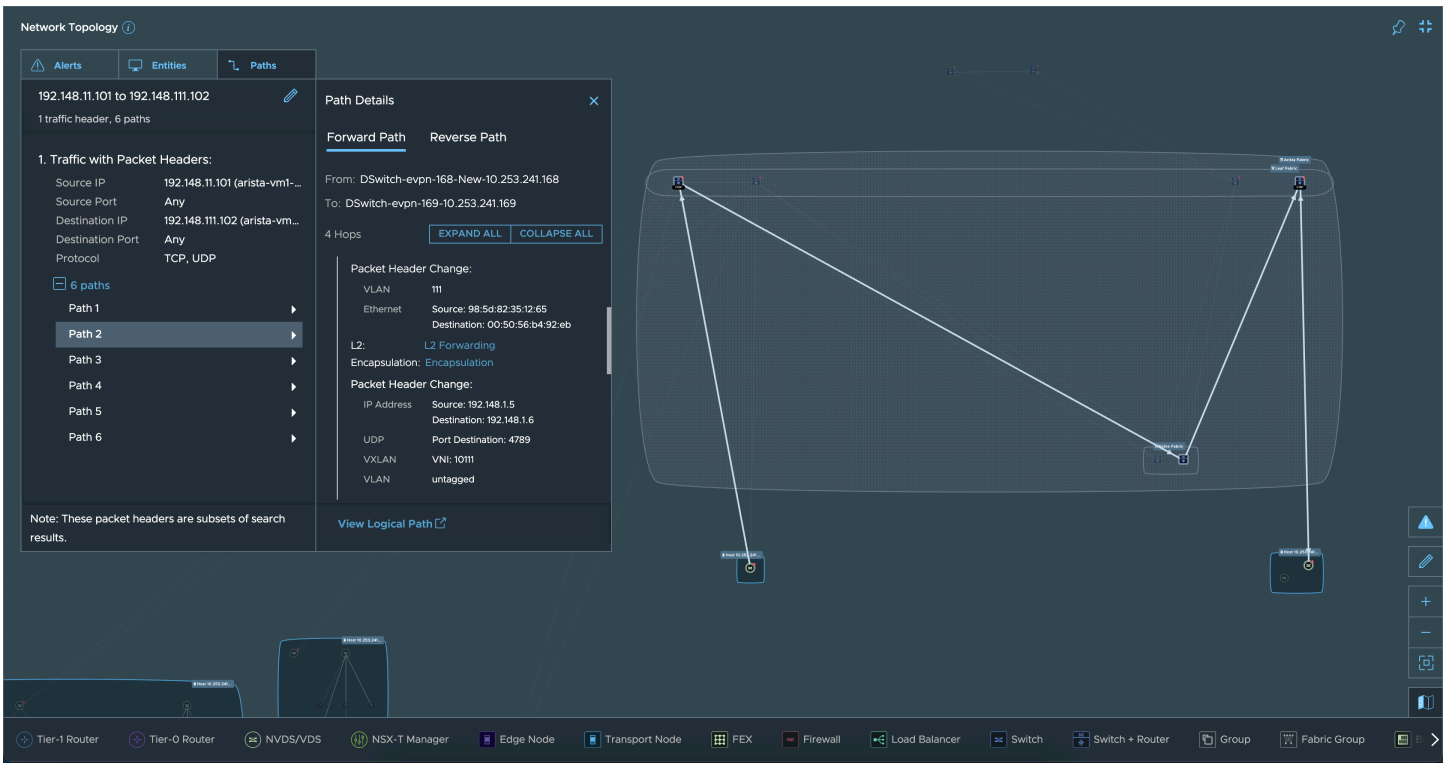


The spine and leaf switches are also displayed when you view the VM-VM path for Arista BGP EVPN on the **Network Map** page.

A sample VM-VM path of Arista BGP EVPN (same VLAN) on the **Network Map** page is as follows:



A sample VM-VM path of Arista BGP EVPN (inter-VLAN) on the **Network Map** page is as follows:

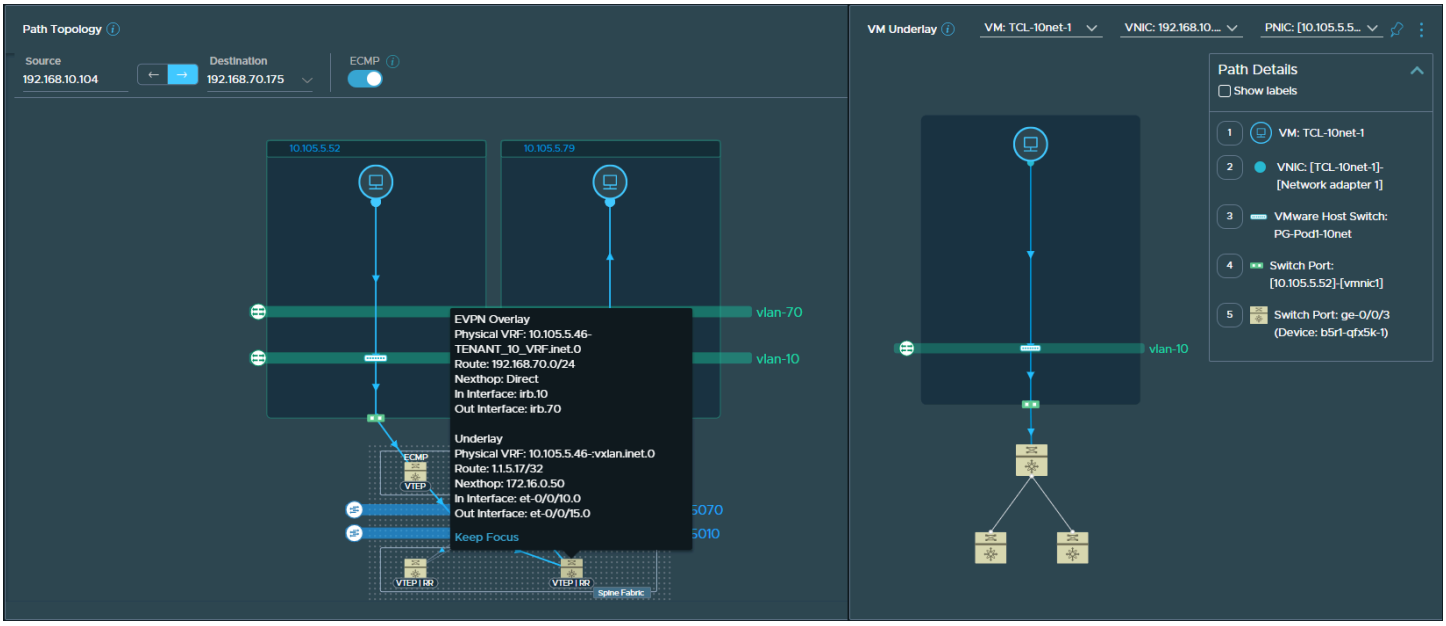


## Support for the Juniper EVPN CRB

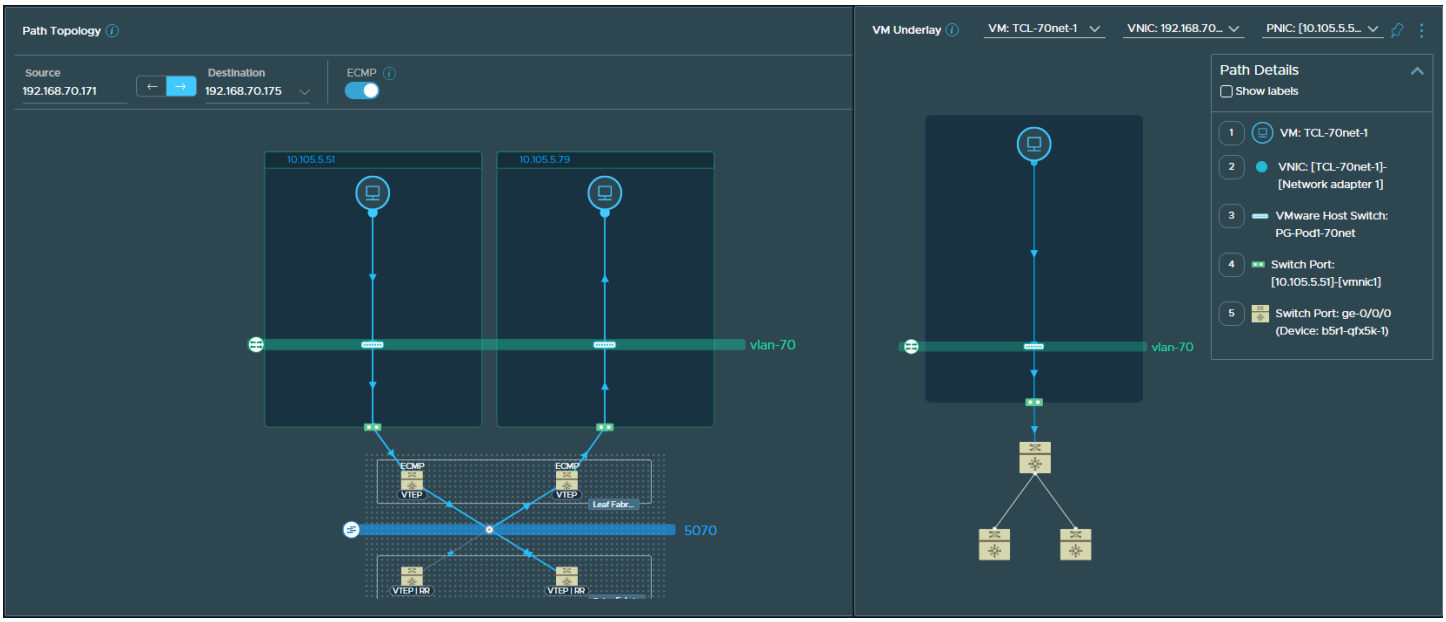
VCF Operations for networks supports the Juniper EVPN Centrally Routed Bridging (CRB) overlay in Asymmetric mode. In CRB, routing happens at the central location with a two layer leaf-spine fabric where the Anycast Gateway (AGW) is

configured on the spine. The AGW is used by the VMs to send out the packets. Here, host is connected to the leaf where the VLAN to VXLAN bridging happens.

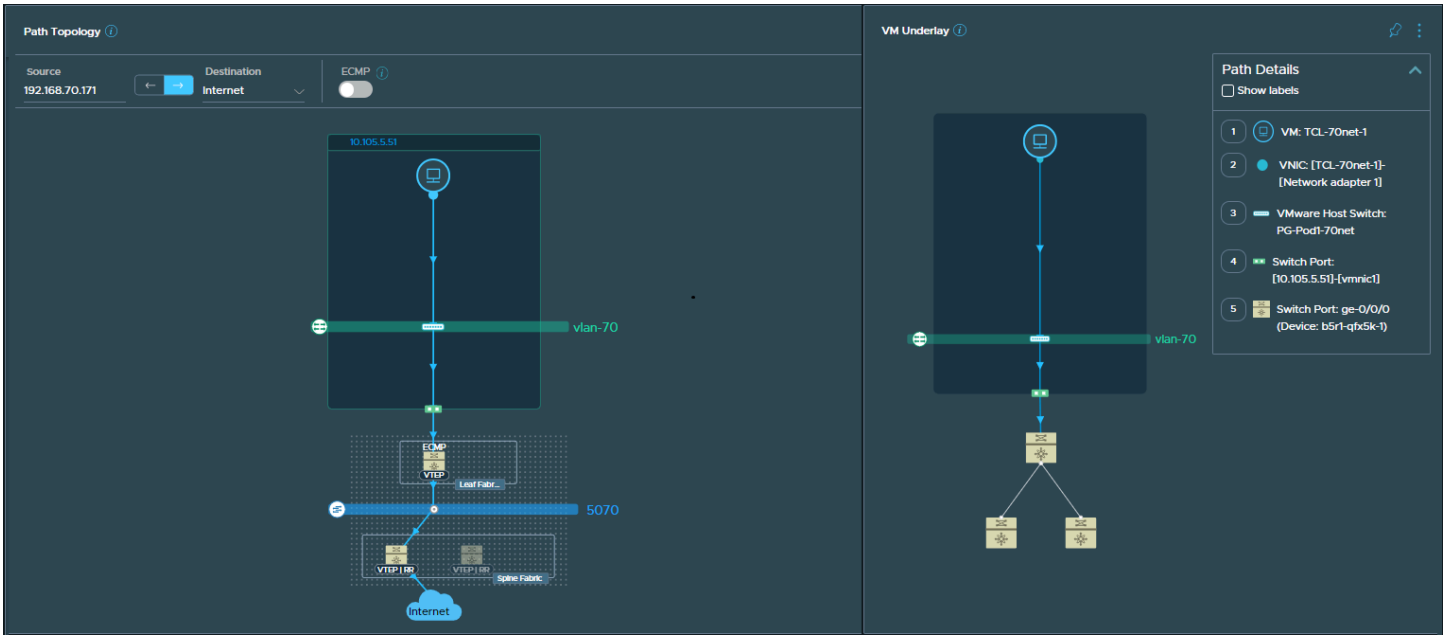
A sample VM-VM path for the Juniper EVPN CRB Inter-VLAN is as follows:



A sample VM-VM path for the Juniper EVPN CRB Same VLAN is as follows:



A sample VM to Internet path for the Juniper EVPN CRB is as follows:

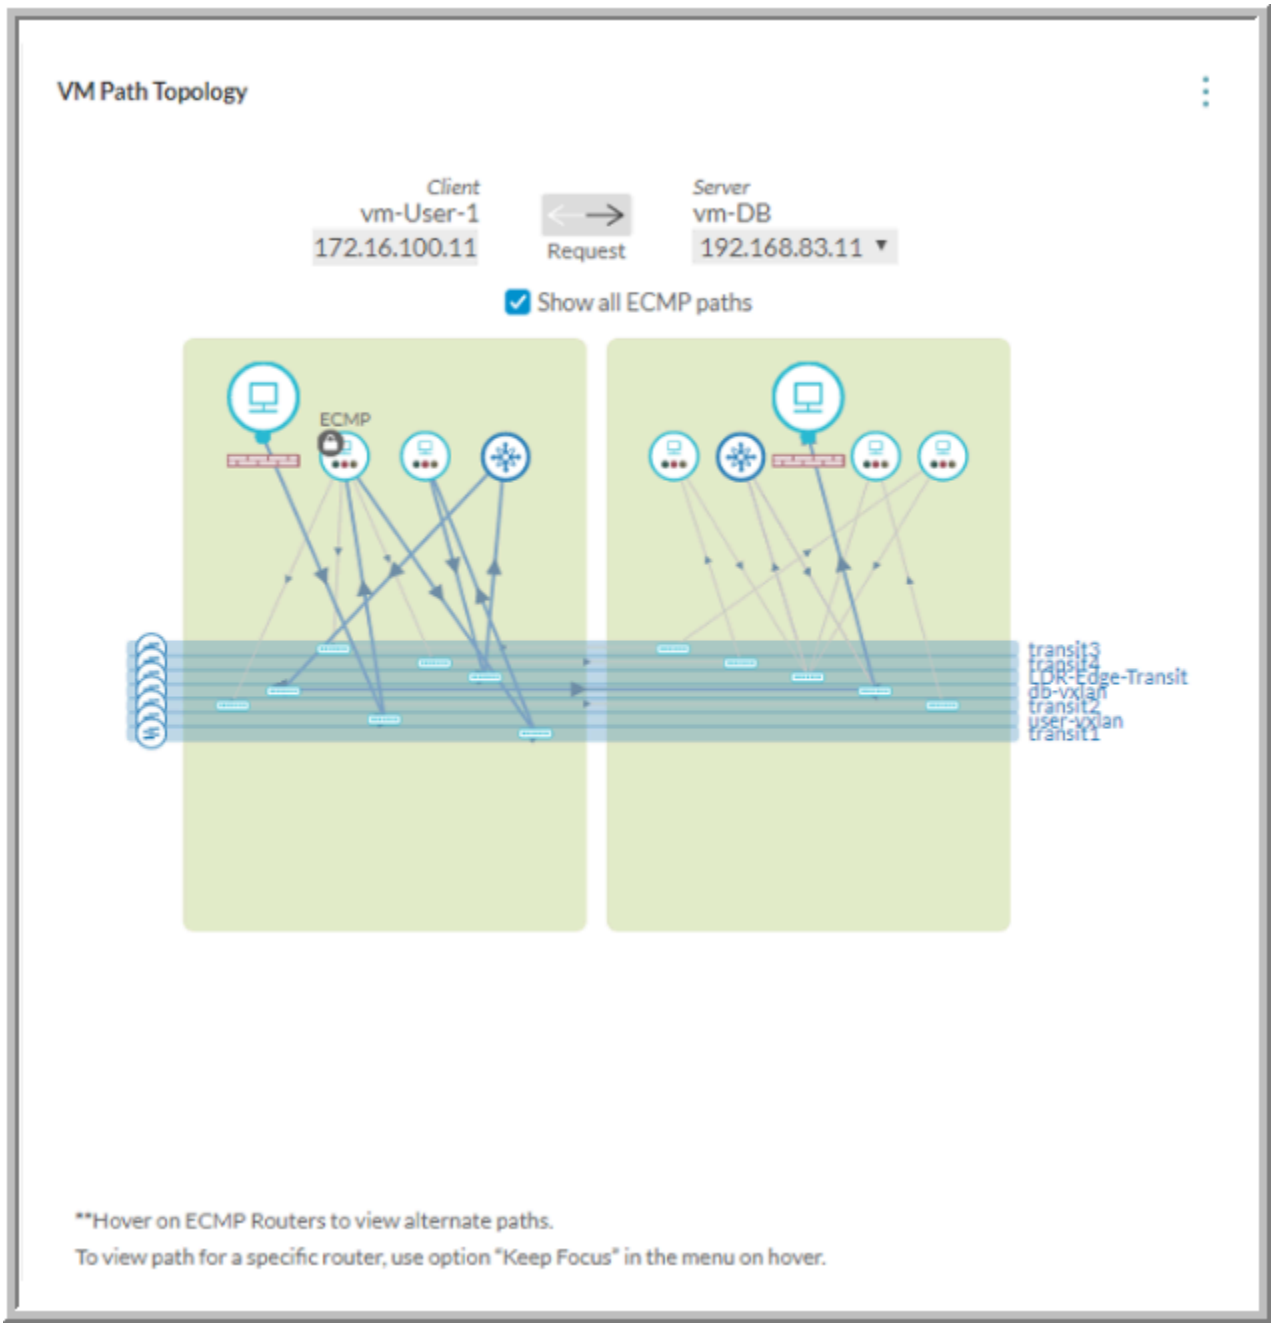


## Support for Equal-Cost Multi-Path (ECMP) Route

VCF Operations for networks provides ECMP support in the VM-VM path.

The VM-VM path shows the following information on ECMP:

- The multiple ECMP paths from source to destination
- The routers on which ECMP occurs
- The possible outgoing paths for a given router (VRF)
- The route for the possible path



In the preceding figure, you can see the ECMP-enabled routers. If you point over them, the additional paths are shown. Also, you can create a path by selecting and locking the routers as per your requirement. If you want to view all the ECMP paths between the two VMs, select the **Show all ECMP paths** option in the topology diagram.

If you want to view the path for a particular router, point on the router and click **Keep Focus**. The paths specific to the router is shown.

### Support for the L2 Bridges

The L2 or the VLAN bridges create a single broadcast domain from multiple VLANs. In the previous releases, if the VM-VM path involved an L2 bridge between two or more VLANs, the VM-VM path did not work. From this release onwards, VCF Operations for networks supports L2 bridging. Currently, this feature is supported only for the Cisco ASA routers.

## View Information on BGP Neighbors

In VCF Operations for networks you can see information on BGP neighbors. You can view the BGP neighbors of an NSX edge or a logical router.

1. Enter `Router where bgp= 'Enable'` in the search bar and press **Enter**.
2. Expand the particular router from list to see the details.

   You can view the following information under BGP neighbors for NSX-T:

   - `IP Address`
   - `Remote AS`
   - `Keep Alive Time`
   - `Hold Down Time`
   - `Status`

   **Note:**

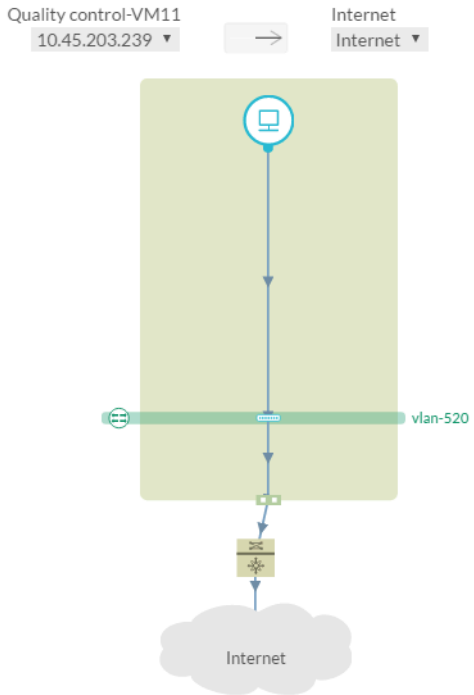
   - If the information regarding the neighbors is not fetched, then the `Status` is shown as `Unknown`.
   - If the `Status` is not `Established.up`, then the `One or more BGP neighbors are not in established state` alert is raised for that edge. You can also view this alert when you search for `problems`.
3. Optional: To view Routers where BGP status is deactivated, search for `Router where bgp= 'Disabled'`.

## Path to Internet

For each virtual machine present in your environment, VCF Operations for networks shows you how the VM is connected to the Internet by using an animated path in the **Path to Internet** pin.

The path populates all the components (both virtual and physical) that exist between the virtual machine and the Internet. It draws an animated path that connects each component in a sequence. The path direction can also be reversed by using the arrows situated above the visualization.

Point your mouse pointer to the entity icons to get their addressable names. Click an icon on the path to display a summarized account of its primary attributes. You can also maximize the pin to see the path details.



# Working with Network Maps and Intents

## Working with the Network Map

Using the network map, you can view a detailed network model of the data sources that are added to VCF Operations for networks.

**Note:**

- The network map is available only for Enterprise and NAV license users who use XL brick.
- Also, network map is supported for a few data sources only. For more information, see Supported Products and Versions.

To access this page, on the VCF Operations for networks home page, click **Network Map**.

The network map contains several elements.

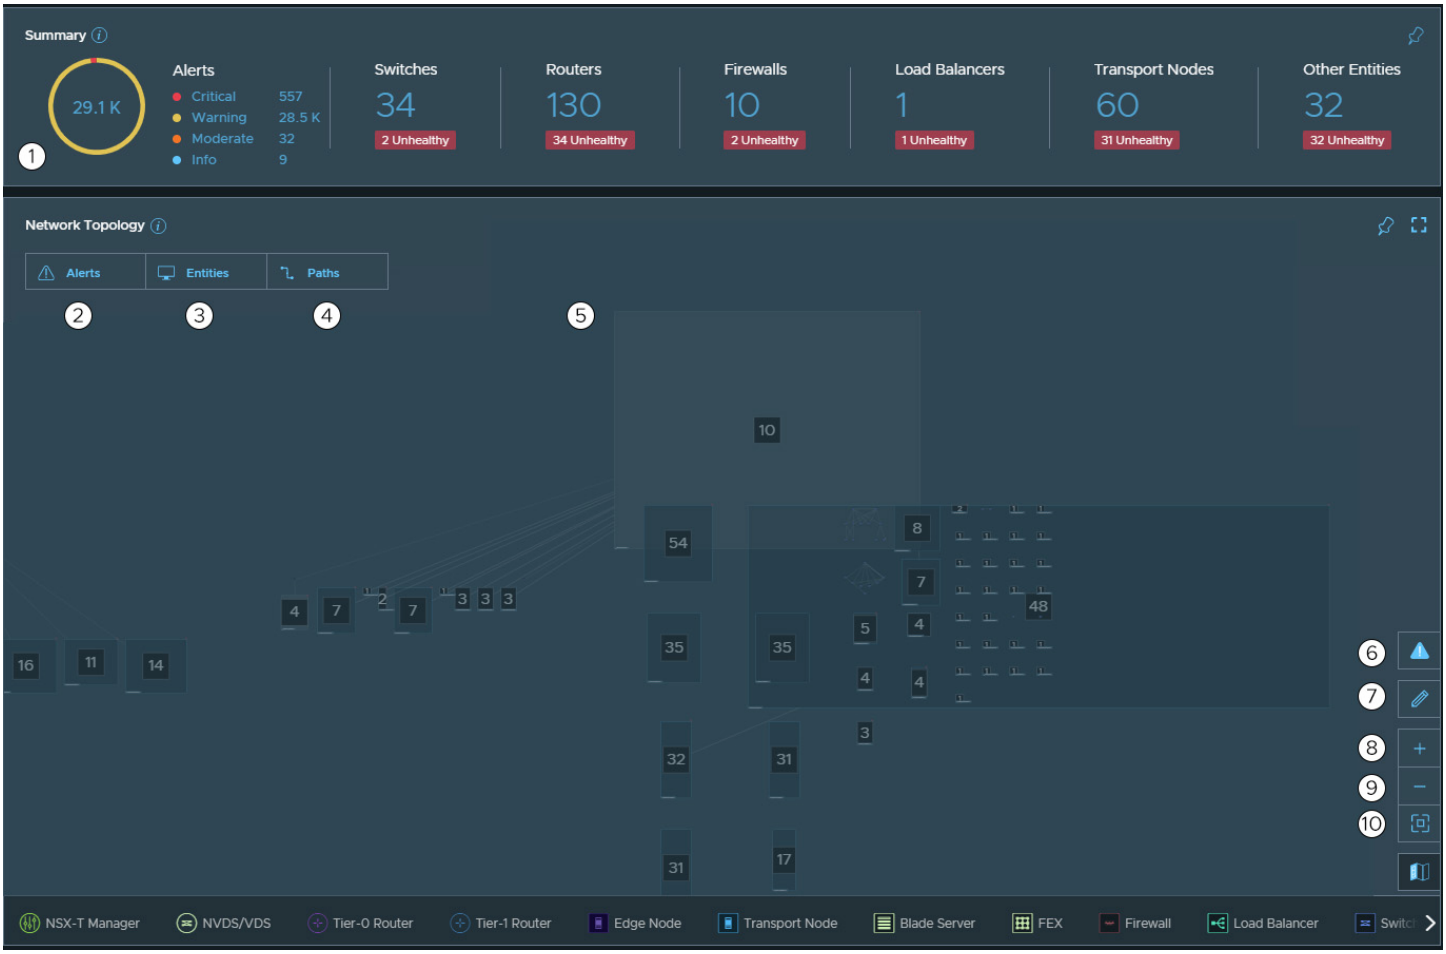


**Table 1332: Elements**

| Elements | Description |
|---|---|
| (1) **Summary** | A summary of your data center which includes an alert chart, switches, routers, firewalls, load balancers, transport nodes, and other entities. |
| (2) **Alerts** | The list of available alerts in your network when you click the **Alerts** tab.<br>You can also search for alerts using the search bar that is available in the **Alerts** tab. To get more details about an alert, click **+** (if available). To see related alerts, click **Expand all**. |
| (3) **Entities** | Entities and groups of entities in your network . All the virtual entities are shown in logical groups. For more information on entities, see Viewing Entity Details. |
| (4) **Paths** | The paths between specified entities. |
| (5) **Network Topology** | An end-to-end interactive topology map of your network including physical and virtual devices. For details, see Network Topology Map. |
| (6) **Alerts** | Hide or show the alerts on the network topology map. |
| (7) **Edit** | Rearrange entities and groups, create groups, and delete groups. To learn about how to create and delete a group, see Add, Edit, or Delete a Group. |
| (8) **Zoom In/Zoom Out** | Zoom in or zoom out of map by clicking the (+) or the (-) button. |
| (9) **Fit to screen** | Rearrange the map to fit the current screen. |
| (10) **Legend** | Show or hide the meaning of each of the icons used in the network topology. |

## Network Topology Map

The network topology map is a map of your entire network at a point in time. VCF Operations for networks constructs this map based on the data collected from all the data sources that are available in VCF Operations for networks and that support network map.

VCF Operations for networks does the following actions:

- Automatically arranges all the virtual entities in different groups for better management.
- Shows the parts of the network affected by alerts so that you can quickly troubleshoot issues.
- Allows you to zoom the network map to see additional details such as group name, entity name, details of an entity, and so on.

## Entities on the Network Map

To see the list of entities and groups of entities available in your network, click **Entities**. All the virtual entities are shown in logical groups. The list of entities can include NSX virtual entities, physical switches, physical firewalls, and so on. For details, see Supported Products and Versions.

To see details about the entities or the groups, click that entity or group. When you click an entity or group, you can see the details of that entity or group and the location of that entity or group in the topology map. You can click ( ) to view more details about that entity and click **Back to summary** to return to the entities list.

You can also search entities or IP addresses in your network using the search bar available in the **Entities** tab. For samples queries, see Search Queries for Entities.

## Auto-layout Map

In the **Network Topology**, you can auto arrange selected entities or your entire map to best fit your screen.

To auto-arrange your **Network Topology**, in **Network Topology** page, click **Edit button** > **Continue** > **Auto-layout map**. You can either auto-arrange entire network topology or a few selected entities.

> **Note:**
> Read the instruction on the UI carefully while using the auto-layout feature.

## Network Map Scope

In the network map, you can view a subset of the map using the **Network Map Scope**; this option enables you to view a more focused version of the network map.

With the **Network Map Scope**, you create a subset of the network map by selecting the entities you are interested in, and the network map creates a network topology only with those selected entities. You can perform the following activities in the network map with **Network Map Scope**:

- Create simple scopes by selecting your choice of entities.
- Edit, modify, or delete existing scopes.
- Toggle between All entities and user-defined scopes using **Scope** drop-down menu.
- Create multiple simple scopes as per your requirement. You can create up to 10 scopes in the network map.

To create a simple scope, do the following:

1. In the **Network Map** page, select **New Scope** > **Create Scope**.
2. In the **Network Map Scope** window, from the **Scope by** drop-down menu, select one of the following:
   – **Entities**: Select entities you want to view in the network map.
   All the entities are segregated in two major categories, virtual entities and physical entities. Each major category has multiple different entity types.

   > **Note:**
   > In the simple scope, you can select entity categories. You cannot select individual entities from the **Scope** drop-down menu.

   > **Note:**
   > The **Network Map Scope** considers only VMware overlay components such as the Edge transport node, the host transport node, and so on as virtual entities, and all third-party virtual appliances, such as F5 BIG-IP VM, Palo Alto VM, Cisco NX-OSv, and so on, as physical entities and grouped under the physical entities.
   – **Groups**: Select groups or subgroups you want to view in the network map. You can also search for groups and sub-groups and select the groups or subgroups you want to view in the network map.
3. Click **Apply**.
   You see a preview of the network map for your scope.
4. Click **Save Scope** located at the top-right corner.
5. If the preview is not per your requirement, click **Discard**.
6. Add a name for your scope, and click **Confirm**.

**Figure 447: Network Map Scope**

You can also edit, delete, or duplicate saved scopes. To edit, delete, or duplicate a saved scope, do the following:

1. In the **Network Map** page, from the **Scope** drop-down located on the top-left corner, select **Manage Saved Scopes**.

2. In the **Network Map: Saved Scopes** page, select the saved scope you want to modify, and do the following:
   - To edit a saved scope, click the **Edit** button, make the required changes and click **Save Changes**.
   - To delete a saved scope, click the **Delete** button and confirm your action.
   - To duplicate a saved scope, click the **Duplicate** button, make the required changes (if necessary), and click **Apply**.

### Search Queries for Entities

Here are some of the sample search queries that you can use in the search bar of the **Entities** tab:

| Search Queries | Description |
|---|---|
| device bb-ny-1 | Shows devices whose name contains 'bb-ny-1'. |
| device 'bb-ny-1' | Shows devices whose name is exactly 'bb-ny-1'. |
| device ny | Shows devices whose name contains 'ny'. |
| abcd | Shows entities whose name contains 'abcd'. |
| 'abcd' | Shows entities whose name is exactly 'abcd'. |
| '1.1.1.1' | Shows entities whose manager IP address is 1.1.1.1. |
| 1.1.1.1 | Shows all the entities whose manager IP address contains 1.1.1.1. For example 1.1.1.1, 21.1.1.12, or 31.1.1.12. |
| device where manager = 1.2.3.4 | Shows device whose manager IP address = 1.2.3.4. |
| host switch | Shows a list of host switches. |
| host switch where name = 'DSwitch-1-localhost' | Shows host switch whose name = DSwitch-1-localhost. |
| host switch where name like 'vds-switch1' | Shows a list of host virtual switches whose name contains 'vds-switch1'. |
| interfaces | Shows a list of all interfaces. |
| interface 'fastethernet0/0' | Shows interfaces whose name contains 'fastethernet0/0'. |
| interface where mac address = 'c401.1cbe.0000' | Shows a list of interfaces whose MAC address contains 'c401.1cbe.0000'. |
| interface where name like vlan | Shows a list of interfaces whose name contain keyword vlan. |
| router interface where ip address = 192.168.10.1 | Shows a list of router interfaces whose IP address contain 192.168.10.1. |
| interface where name like 'ethernet' and start vlan = 10 | Shows a list of interfaces whose name contain 'ethernet' and whose VLAN range start from VLAN 10. |
| router interface where ip address = 192.168.1.0/24 | Shows a list of interfaces whose IP address falls within the given subnet 192.168.1.0/24. |
| 00:01:02:03:04:05 | Shows a list of interfaces whose MAC address is 00:01:02:03:04:05. |
| host router | Shows a list of all virtual routers available in all the hosts. |
| host router where name like 'tier0' | Shows a list of all virtual routers whose name contain 'tier0' |
| port channel where administrative status = 'down' | Shows a list of all port channels whose administrative status is down. |
| network device group | Shows a list of all user created groups and auto inferred hosts as groups. |

### Paths on a Network Map

To find paths between specified entities -

1. In the **Network Topology** section, click **Paths**.
2. Enter the source and destination VMs , and click **Show Paths**.

**Note:**
Powered off VMs are not supported while performing a path search on the Network Map page. If you manually enter a powered off VM name in the **Source** or **Destination** field, path search will display the `Unknown Source` or `Unknown Destination` error message.

To know more about path search, see Use Advanced Path Search.

VCF Operations for networks also supports subnet to subnet path search on network maps.When you click **SHOW PATHS**, the system searches the model of your network available in VCF Operations for networks to find all possible paths matching the search parameters. The results are grouped according to traffic headers. Each traffic header description contains a list of paths that the packets with those headers can follow. There can also be more than one path. For example, you can see multiple paths if your network uses multipath forwarding. You can see a maximum of 25 results in the list. If necessary, you can narrow your search parameters to see all results.

Click **Path N** (N = numerical digit, example: 1, 2, 3, and so on) to see **Path Details**. In the **Path Details**, you can see the forward path, reserve path, hops details and so on.

### Path Search Queries

Following are some sample path search queries:

| From | To | Expected Result |
|---|---|---|
| `switch port where routedportips = 61.0.1.1` | `switch port where routedportips = 61.0.1.2` | Shows paths from routed port with IP 61.0.1.1 to routed port with IP 61.0.1.2 |
| `interface 'ethernet1' where Device = 'R1-arista'` | `interface 'ethernet1' where Device = 'R2-arista'` | Shows paths from interface ethernet1 of R1-arista to interface ethernet1 of R2-arista |
| `61.0.1.1` | `61.0.1.2` | Shows paths from 61.0.1.1 to 61.0.2.1 where both IPs are of routed ports |
| `61.0.1.0/24` | `63.0.1.0/24` | Shows all paths from subnet 61.0.1.0/24 to subnet 63.0.1.0/24. |
| `61.0.1.10` | `63.0.1.0/24` | Shows paths from IP address 61.0.1.10 to subnet 63.0.1.0/24. |

## Use Advanced Path Search

With Advanced Path Search, you can add more filters in your path search.

1. On the VCF Operations for networks home page, click **Network Map**.
2. In the **Network Map** page, click **Paths**.
3. In the **Source** and **Destination** text boxes, enter an entity query or IP address that you want to search. In general, you can use any query in the **Source** and **Destination** text boxes. For sample queries, see Search Queries for Entities.

   Searches can match multiple entities, so that you can search for paths between a set of sources and a set of destinations.

   **Note:**

   - Powered off VMs are not supported while performing a path search on the Network Map page. If you manually enter a powered off VM name in the **Source** or **Destination** field, path search will display the `Unknown Source` or `Unknown Destination` error message.
   - You cannot use a Cisco Nexus 2000 series fabric extender devices as a source or a destination as this device cannot generate or consume traffic.
4. Optional: To find the paths that traverse certain intermediate entities, click **Add a Hop**.

   You can add multiple hops.

5. To add more option in your path search, click the **Advanced Options** check box and provide the required information.

| Option | Action |
|---|---|
| **Packet Headers at Source** | Select one of the following:<br>• **Source Port**: Source transport port.<br>• **Destination Port**: Destination transport port.<br>• **Protocol**: Transport protocol. |
| **Path Type** | Select one of the following:<br>• **Primary**: To see the primary paths.<br>• **Backup**: To see the backup paths.<br>• **All**: To see all available types of paths. |
| **Path Direction** | Select one of the following:<br>• **Forward**: To see paths only in the forward direction.<br>• **Bidirectional**: To see the full round-trip path from source to destination and back. |
| **Path Status** | Select one of the following:<br>• **All**: To see both reachable and blocked paths.<br>• **Reachable**: To see paths for which packets reach the destination.<br>• **Blocked**: To see paths for which packets are blocked before reaching the destination. For example, because they are dropped by a firewall, dropped at a routing black hole, or are caught in a loop. |

6. Click **SHOW PATHS**.

## Add, Edit, or Delete a Group

In the **Network Map** page, you can group multiple entities together for the better management and visibility. In the **Network Map** page, groups define a set of multiple entities. A group can also contain other groups. Groups are used to organize the entity list and to provide a context to the visualization in the network map. You can also use groups when searching for entities and paths.

VCF Operations for networks automatically creates certain types of groups. For example, the system groups virtual entities inside the same physical host. You can also add, edit and delete your own groups.

**Note:**
You cannot edit or delete system-generated groups.

1. In the **Network Map** page, click **Edit** in the lower-right corner.
2. After you click **Edit**, you can do the following:

| Option | Action |
|---|---|
| **Add a group** | To add a group, do the following:<br>1. Click the **Add Group** icon located in the lower-right corner.<br>2. In the **Create Group** window, in the **Name** text box, enter a group name.<br>3. From the **Entities** drop-down, select all the entities that you want to add in the group.<br>**Note:**<br>• You can select entities using device name, groups, IP address, IP range or subnet, and custom search.<br>• You can use combination of these options to find entities.<br>• You can also select entities in the **Network Topology** to create groups. You can only select entities which are not part of any previous group. You can not select entities which are part of any existing groups, but you can select a top-level group to create a new group.<br>• The custom search enables you to find entities using SQL like queries. |

| Option | Action |
|---|---|
| | • If you use the IP range/subnet or custom search to create a group, the group can change size dynamically. This happens because, based on your search criteria, devices get added or removed automatically to the group when any data sources get added or removed in VCF Operations for networks.<br>• When using the IP range/subnet or custom search option to create groups, if an entity matches more than one group, then the entity gets added to the group whose name comes first in alphabetical order.<br>4. From the **Color** drop-down, select a color for the group, and click **Submit**. |
| **Edit a group** | To edit a group, do the following:<br>1. Select the user-defined group that you want to edit, and click **Edit Group**.<br>2. In the **Edit Group** window, do the required changes.<br>3. Click **Submit**.<br>**Note:**<br>You can only edit user-defined groups. You cannot edit system-generated groups. |
| **Delete a group** | To delete a group, do the following:<br>1. Select the group you want to delete, and click **Delete Group**.<br>2. In the **Confirm Action** window, click **Confirm**. |

## Create and Delete Groups by Using a CSV File

You can use the network map group tool to create and delete groups by adding a CSV file.

To use a CSV file to create a group in your network map, the file must include the following three mandatory columns:

- `Member`: Includes the member, which can be a device or subgroup, you want to add. The member can be identified through a name or IP address. The device or subgroup must be part of the network map. If the member is a subgroup, it must be a top-level group available in the network map. The member must not be part of any other group. If the member is a device, it should be an orphan device, not part of any existing group.

  **Note:**
  If the IP address is used as the identification method for a member, it is expected to be the manager IP address. For managed devices, such as Panorama or Check Point, the expected IP address is the device IP address. If the member is a ESX host group, either group name or host IP address can be specified as the member.
- `GroupName`: Includes the name of the new group that you want to create. It must not be part of the network map.
- `Color`: Includes the color coding for the group. If the color you want to add is spelled with two words, the words should be separated by a whitespace. For example, Lemon Yellow. Supported colors include Black, Blue, Brown, Cyan, Gold, Green, Grey, Lemon Yellow, Light Grey, Light Red, Magenta, Mustard, Navy Blue, Neon Green, Neon Pink, Olive Green, Orange, Purple, Red, Sea Green, Sky Blue, and Violet.

The following are two example CSV files. The first example includes device members, while the second includes subgroup members.

```
Member,GroupName,Color
d1,g1,Red
d2,g1,Red
d3,g3,Lemon Yellow
d4,g3,Lemon Yellow
d5,g4,Green
10.10.10.10,g5,Cyan
```

```
Member,GroupName,Color
g1,g2,Blue
g2,g3,Blue
g3,g4,Cyan
g5,g6,Red
g7,g8,Magenta
```

1. Log in to the VCF Operations for networks command line interface.
2. Optional: To validate your new group before creating it, you can run the network map group tool command with the `-v` argument.

   To validate a group with subgroup members, for example, run the `network_map_group_tool -path <pathToFile> -m group -v` command.
3. To create a group with subgroup members, run the `network_map_group_tool -path <pathToFile> -m group` command.
4. To create a group with device members, run the `network_map_group_tool -path <pathToFile> -m device`.
5. To delete all groups specified in a given CSV file, run the `network_map_group_tool -d -path <pathToFile>` command.
6. To delete all user defined groups, run the `network_map_group_tool -d`.

### Troubleshooting Network Map Related Errors

The table lists errors you might encounter when using the **Network Map** with the cause and resolution steps.

| Error Text | Cause | Resolution |
|---|---|---|
| `Path search and intent verification may not be available in Network Map.` | Network-wide rule count has exceeded the current platform capacity. | You must switch your deployment to a cluster of bigger size. Contact VMware support. |
| `The network map and intent verification are unavailable due to insufficient Operations for Networks platform resources.` | Network-wide rule count has exceeded the current platform capacity. | You must switch your deployment to a cluster of bigger size. Contact VMware support. |
| `No data to show.` | No supported data source added. | You must add supported data sources and wait for 30 minutes. |
| `No data to show.` | Supported data source is present, but deactivated. | You must enable collection from supported data sources and wait for 30 minutes. |
| `Path search and intent verification may not be available for some devices.` | Number of rules set by one or more devices has exceeded the supported limit. Or, one or more devices have encountered processing errors. | You must contact VMware support. |
| `Showing only physical network entities on the map.` | Number of Network Map elements have exceeded the supported limit. | You must contact VMware support. |
| `Encountered an error.` | Can be due to various reasons. | You must contact VMware support. |

## Working with Intents

An intent is a desired property of your network. An intent can describe a business policy or an architectural goal. You can use intents to design, manage, and to verify networks based on business policies. Intents enable prediction of network behavior in advance.

VCF Operations for networks provides a powerful set of system defined intents out-of-the-box. You can also configure custom user-defined intents from a menu of intent templates.

Periodically, VCF Operations for networks verifies whether each intent is satisfied, using a model of all possible network-wide behavior. If an intent is violated, it triggers an alert.

**Note:**
This feature is available only for Enterprise License users using XL brick.

## Viewing Intent Details

VCF Operations for networks classifies intents as either system-defined or user-defined.

System-defined intents are provided out-of-the-box. You can clone a system-defined intent to create a user-defined copy, which you can then edit to change its parameters. System-defined intents are enabled by default, but you can deactivate them from the **Manage Intents** page.

You can define and configure new intents in VCF Operations for networks. The intents that you define are called user-defined intents. You can edit, delete, and duplicate these intents. You can also select multiple user-defined intents and enable or deactivate them at once.

Every 30 minutes, VCF Operations for networks verifies whether each intent is met in your network.

- If the system determines that the intent's specified conditions are met at that time, it marks the intent status as `Pass`.
- If the intent's specified conditions are not met, the system raises an alert corresponding to this problem and marks the intent status as `Fail`. If the alerts associated with an intent are closed or archived, then the intent status becomes `Pass`.
- If the system determines that one or more entities in the intent configuration are no longer available, it marks the intent status as `Invalid` and displays the `Entity not available` warning message with the intent name.
  Also, when you edit the configuration parameters of the invalid intent, the system highlights the invalid entities in red.

  **Note:**

  VCF Operations for networks does not process invalid intents. That is, if an intent is invalid, VCF Operations for networks does not verify whether the conditions defined in the intent are met in your network.

  To validate the intent, you must delete or replace the invalid entities in the intent configuration.

You can access the **Intents** page from the left navigation pane. You can view the count of all intents and the count of each individual type on this page. You can click each count to filter and view the details of specific types of intents.

VCF Operations for networks supports many different types of intents for a range of purposes. These intent types are grouped into three broad categories:

- Device Health
- Network Health
- STIG

  **Note:**
  STIG intents are supported for the following devices only:

  - Cisco ASA, Cisco ASR 1000, Cisco Catalyst, Cisco ISR 4000, and Cisco Nexus
  - Juniper EX and QFX, Palo Alto

You can filter the intents based on the intent type or intent category. You can view the count of alerts raised by each intent, and you can click this count to see the alert details.

You can also view the intent status (Pass or Fail) and the severity (Critical, Moderate, Warning, Info) of each available intent.

You can also search intents in the list based on their names.

## Define an Intent

You can define and configure new user-defined intents in VCF Operations for networks. After defining an intent, you can edit, delete, duplicate, enable, or deactivate the intent at any time.

**Note:**
VCF Operations for networks supports a maximum of 1,000 intents. If you have 1,000 intents in your environment, you cannot define any more intents. You must delete existing intents to define any new intents.

1. On the left navigation pane, click **Manage Intents**.
2. On the Intents page, click **DEFINE INTENT**.
3. Expand a category under **Intent Type** and click **Select** on the type of intent you want to create.

   **Note:**
   You cannot edit the intent type after creating the intent. However, you can use the **Change Intent Type** option to change the type while you are in the process of defining the intent.
4. Enter the intent parameters which includes the intent name, the intent severity, intent tags, and notes (optional).

   The parameter list displays additional options based on the intent type you select.
5. Optional: Select the **Include/Exclude entities** check box to limit the defined intent to certain entities.
   a) Choose an action depending on your requirement:

| Action | Procedure |
|---|---|
| Include | To add the entities on which the intent should apply, perform the following steps:<br>1. Click **Include**.<br>2. From the drop-down menu, do one of the following actions:<br>— Select a predefined entity and enter your search query.<br>— Select **Custom query** and enter a custom search query.<br>If you select **L3 Switch Manager** or **Custom search**, you can use **Add exception** to exclude certain entities from the query result.<br>For example, if you use a custom query to select all the Node Ids that are lesser than 3, you can add an exception on Node Id 0. Then, the defined intent applies on Node Ids 1 and 2. |
| Exclude | To add the entities on which the defined intent should not apply, perform the following steps:<br>1. Click **Exclude**.<br>2. From the dropdown menu, do one of the following actions:<br>— Select a predefined entity and enter your search query.<br>— Select **Custom query** and enter a custom search query.<br>If you select **L3 Switch Manager** or **Custom search**, you can use **Add exception** to apply the intent on one or more excluded entities.<br>For example, if you use the custom query to select Node Ids that are lesser than 3, you can add an exception on Node Id 1. Then, the defined intent applies on all Node Ids except ports 0 and 2. |

   b) To add another condition, Click **Add Condition**.
6. Under **Alert Notification**, select how you want to get the alert notifications.

   You get the alert notification on the configured email address or SNMP Trap destination. You can select multiple check boxes as per your requirement.
7. Click **Submit**.

   You can view the new intent on the Intents page.

When you create an intent, VCF Operations for networks immediately verifies whether the conditions defined in the intent are met in your network. If the intent is violated, the system raises an alert corresponding to this problem and marks the intent status as Fail.

## Supported Intent Types

VCF Operations for networks supports the following intent types.

| Group (Category) | Intent Type | Name | UI Name | Severity | Virtual/Physical | Description |
|---|---|---|---|---|---|---|
| STIG | Account Password Protection | Account Not Password Protected | Administrative account access is not password protected on the following devices. | High | Physical | The network device must be password protected for administrative access. |
| | Console Access Password Protection | Console Access Not Password Protected | Console port access is not password protected on the following devices. | High | Physical | The network device must require authentication for console access. |
| | Default Password Existence | Default Password Existence | Default manufacturer password is used on the following devices. | High | Physical | The network device must not have any default manufacturer passwords. |
| | Management Connection Password Protection | Management Connection Not Password Protected | Management port access is not password protected on the following devices. | High | Physical | The network device must require authentication prior to establishing a management connection for administrative access. |
| | Plaintext Password Visibility | Plaintext Password Visibility | Plaintext passwords are visible on the following devices. | High | Physical | The network device must not have plaintext passwords. |
| Network Health | Duplex Mismatch | Duplex Mismatch | Duplex configuration does not match on the following ports. | Critical | Physical, Virtual | Port duplex configuration of the ports on each link should match. |
| | Duplicate IP Address | Duplicate IP Address | Duplicate IP address has been configured on the following interfaces. | Critical | Physical | Duplicate IP address should not be configured on multiple interfaces. |
| | Duplicate MAC Address | Duplicate MAC Address | Duplicate MAC address has been configured on the following interfaces. | Critical | Physical | Duplicate MAC address should not be configured on multiple interfaces. |
| | HSRP/VRRP Configuration Error | HSRP/VRRP Configuration Error | HSRP Configuration contains the following error. | Critical | Physical | Check for HSRP/VRRP configuration mismatch between Active and Standby. |
| | Loop Detection | Loop Detection | Network contains the following loop. | Critical | Physical, Virtual | Network should be loop free. |
| | Native VLAN Mismatch | Native VLAN Mismatch | Native VLAN configuration does not match on the following ports. | Critical | Physical | Native VLAN configuration of the ports on each link should match. |
| | Native VLAN Tagging Mismatch | Native VLAN Tagging Mismatch | Native VLAN Tagging does not match on the following ports. | Critical | Physical | Native VLAN tagging of the ports on each link should match. |
| | Port Channel Member Mismatch | Port Channel Member Mismatch | Port channel member ports should not connect to non-member ports on linked devices. | Critical | Physical | Port channel member ports should not connect to non-member ports on linked devices. |
| | Port Mode Mismatch | Port Mode Mismatch | Port mode configuration does not match on the following ports. | Critical | Physical | Port mode configuration should match on the ports of each link. |

| Group (Category) | Intent Type | Name | UI Name | Severity | Virtual/Physical | Description |
|---|---|---|---|---|---|---|
| | Reachability | Reachability Failure | Network endpoints should be reachable. | Critical | Physical, Virtual | Network endpoints should be reachable. |
| | STP Path Cost Method Inconsistency | STP Path Cost Method Consistency | Inconsistent STP path cost methods have been configured on the following switches. | Moderate | Physical | STP path cost calculation methods should be consistent among switches. |
| | Segmentation | Segmentation Failure | Network endpoints should be segmented. | Critical | Physical, Virtual | Network endpoints should be segmented.<br>**Note:** Segmentation Intent verifies that specified source cannot communicate with destination, even using spoofed source IP addresses. |
| | Trunk VLAN Mismatch | Trunk VLAN Mismatch | Allowed VLANs configuration does not match on the following trunk ports. | Critical | Physical, Virtual | Allowed VLANs configuration should match on the ports of each trunk link. |
| Device Health | HSRP/VRRP Active STP Root Colocation | HSRP/VRRP Active STP Root Colocation | HSRP/VRRP Active should be colocated with STP Root, if both protocols are enabled. | Moderate | Physical | HSRP/VRRP Active is not colocated with the following STP Root. |
| | MTU Mismatch | MTU Mismatch | MTU configuration of the ports on each link should match. | Moderate | Physical, Virtual | MTU configuration of the ports on each link should match. |

**Note:**

- STIG intents are supported for the following devices only:
  - Cisco ASA, Cisco ASR 1000, Cisco Catalyst, Cisco ISR 4000, and Cisco Nexus
  - Palo Alto
- The STP Path Cost Method Inconsistency intent is supported only for Cisco Catalyst and Cisco Nexus devices.
- If a device is configured with port channel sub interfaces (that are associated with different VLANs), or configured with port mode and allowed VLANs that are configured at the port channel level, such configurations are considered while performing intent analysis for the following devices only:
  - Arista switches
  - Dell EMC PowerSwitch S5200 (running on OS10)

## Supported Application Intent Types

In VCF Operations for networks, you can view various types of application intents.

The supported application intents are:

| Group (Category) | Intent Type | Severity | Virtual/Physical | Description |
|---|---|---|---|---|
| Application | Application Flow Health | Critical | Physical, Virtual | Monitors flow health of application at tier level. |

| Group (Category) | Intent Type | Severity | Virtual/Physical | Description |
|---|---|---|---|---|
| | Application Flow Utilization | Critical | Physical, Virtual | Monitors flow utilization of application at tier level. |

**Note:**

- Once you add the application intents, it can take upto 26 hours for the intent violations to get generated.
- VCF Operations for networks removes all system generated application threshold configurations and the alerts related to those threshold configuration.
- For applications that had threshold enabled before VCF Operations for networks version 6.8 upgrade, VCF Operations for networks automatically enables intents for these applications after the upgrade.
- The applications that did not have any thresholds enabled before the VCF Operations for networks version 6.8 upgrade, those applications are moved to the intents exclusion list after the upgrade.

# Supported Firewalls

VCF Operations for networks supports several firewall.

## Cross vCenter NSX

In a cross-vCenter NSX environment, you can have multiple VMware vCenter servers, each of which must be paired with its own NSX Manager.

One NSX Manager is assigned the role of primary NSX Manager, and the others are assigned the role of secondary NSX Manager. The primary NSX Manager is used to deploy a universal controller cluster that provides the control plane for the cross-vCenter NSX environment. The secondary NSX Managers do not have their own controller clusters. The primary NSX Manager can create universal objects, such as universal logical switches. These objects are synchronized to the secondary NSX Managers by the NSX Universal Synchronization Service. You can view these objects from the secondary NSX Managers, but you cannot edit them there. You must use the primary NSX Manager to manage universal objects. The primary NSX Manager can be used to configure any of the secondary NSX Managers in the environment.

The following Universal objects are supported:

- Universal LDR
- Universal Transport Zone
- Universal Logical Switch
- Universal Firewall Rule
- Universal Security Group
- Universal IPSets
- Universal Service
- Universal Service Groups
- Universal Segment Range

## Palo Alto Firewall

VCF Operations for networks displays Palo Alto physical devices in VM-VM path, if the device is available in path.

When you click the device icon in the VM-VM path, you see basic information such as interfaces, routes, and applicable Palo Alto firewall rules.

You can create and register multiple service definitions in Panorama with a given NSX manager. When different ESX clusters have workloads that require the VM Series firewall to handle traffic differently, then multiple service definitions are created. Each service definition has an associated device group from which the policies are picked.

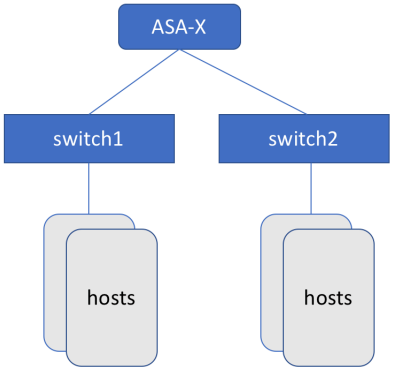
VCF Operations for networks supports Palo Alto policies defined both local to the device, and through Panorama. However, it does not support Inter-VSYS routing.

## Cisco ASA Firewall

VCF Operations for networks supports Cisco ASA firewall.

The features for Cisco ASA firewall are as follows:

- VCF Operations for networks supports only Cisco ASA-X series.
- VCF Operations for networks does not support Firepower modules.
- Currently, VCF Operations for networks supports Cisco ASA operating system version 9.4.
- VCF Operations for networks does not support the cluster deployment of Cisco ASA.
- VCF Operations for networks does not support the high availability of Cisco ASA.
- VCF Operations for networks does not support Cisco ASA if it is directly connected to the host. A topology that is similar to the following example is supported:



- Cisco ASA access rules of only `Extended` type are supported. Other access rule types like `Standard`, `WebType`, `EtherType`, and so on are not supported.
- The Cisco ASA firewall in the VM-to-VM path does not display applicable access rules if the firewall is configured in the `Transparent` mode.

You can perform a query for all the Cisco ASA entities that are supported by VCF Operations for networks.

| Entities in Cisco ASA | Keywords | Sample Queries |
|---|---|---|
| Security Context | ASA Firewall<br>ASA Security Context | `asa firewall where access group = <>` |
| Access Rule | ASA Access Rule | `asa access rule where source ip = <>`<br>`asa access rule where destination ip = '192.168.2.2'`<br>`asa access rule where port = <>`<br>`asa access rule where interface = <>` |

## Check Point Firewall

The Check Point Management Server should accept API access from the Collector IP address.

You can set up the access from Check Point SmartConsole application. Go to **Manage & Settings** > **Blades**, and in the **Management API Setting** window, select **All IP addresses**.

If Check Point MDS is added as data-source, VCF Operations for networks fetches data from all the user-defined domains and the global domain.

VCF Operations for networks uses Check Point public Web API for fetching the data from the Check Point management server. If the VSX gateway is attached to the management server, we use SSH-based CLI commands to fetch the VSX-managed Virtual System VS routing table to support display of the VS gateway in the VM-VM path.

You can perform a query for all the Check Point entities that are supported by VCF Operations for networks. All the entities are prefixed by `Check Point`.

**Table 1333: Sample Queries for Check Point**

| Entities in Check Point | Keywords | Queries |
|---|---|---|
| IPset | `Check Point Address Range`<br>`Check Point Network` | `vm where Address Range = <>`<br>`vm where Address Range = <>`<br>`Check Point Address Range where Translated VM = <>` |
| Grouping | `Check Point Network Group` | `Check Point Network Group where Translated VM = <>`<br>`vm where Network Group = <>` |
| Service/ Service Group | `Check Point Service`<br>`Check Point Service Group` | `Check point service where Port = <>`<br>`Check point service where protocol = <>` |
| Access Layer | `Check Point Access Layer` | `Check Point Policy where Access Layer = <>` |
| Domain | `Check Point Domain` | `check point domain where ip address = <>`<br>`check point policy where domain = <>`<br>`check point access layer where domain = <>` |
| Gateways and Gateway Cluster | `Check Point Gateway`<br>`Check Point Gateway Cluster` | `Check Point Gateway Cluster where Policy Package = <>` |
| Policy Package | `Check Point Policy package` | `Check Point Policy where Policy Package = <>`<br>`Check Point Policy Package where Rule = <>` |
| Policy | `Check Point Policy` | `Check point policy where source ip = <> and Destination IP = <>`<br>`Rule where source ip = <> and Destination IP = <> (will display other rules- nsx, redirect along with check point policies in the system)` |

If the Check Point device is present in the VM-VM path, you can see the device's physical gateways and virtual system in the VM topology. When you click the device icon, you can see basic information such as interfaces, routes, and applicable Check Point firewall rules.

> **Note:**
> For the VM-VM path, VCF Operations for networks does not support the VSX cluster containing Virtual Switch and Virtual Router.

Here are some scenarios for which the system alerts are generated for Check Point:

- The NSX fabric agent is not found on the ESX for the Check Point gateway.
- The Check Point service VM is not found.
- The Check point gateway `sic` status is not communicating.
- The discovery and update alerts features for the Check Point entities like address range, networks, policies, groups, policy package, service, service group, and so on.

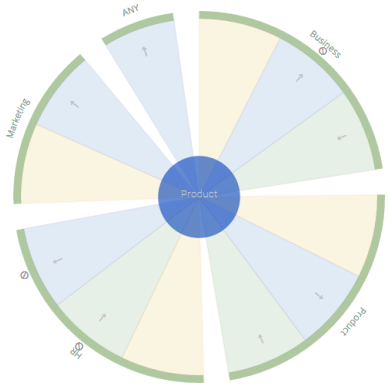
## Security Groups

Security Groups are a set of groups that are managed through a common set of permissions.

The Security Group topology has the following two views:

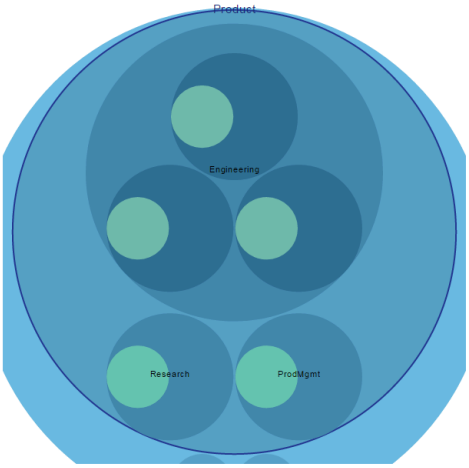
### Firewall View

The Security Group firewall topology displays the relation between the selected Security Group and other Security Groups by showcasing the firewall rules that are applicable between the Security Groups.



### Container View

The Security Group container topology displays how the Security Group is structured with respect to its parent Security Groups or children (Security Groups or other entities).



## Policy-Based VPN

VCF Operations for networks supports policy-based VPN in VMware Cloud on AWS and NSX-T. The following scenarios are supported for the policy-based VPN:

- VPN tunnel between the VMware Cloud on AWS public IP address and the NSX-T/AWS public IP address

- VPN tunnel from the VMware Cloud on AWS public IP address and the corporate firewall public IP address to a 1:1 NAT between the corporate firewall public IP address and the internal NSX Edge

  **Note:**
  VCF Operations for networks does not support the scenario of the VPN tunnel from the VMware Cloud on AWS ending on a corporate firewall and no NAT configured with the internal NSX edge.

**Policy-Based VPN Entities**

VCF Operations for networks fetches data for the `L3 VPN Session` entity which is the actual VPN configured in the data center.

Here are the search terms for the policy-based VPN entities:

**Table 1334:**

| Search terms | Description |
|---|---|
| `Policy based VPN` | All policy-based VPN sessions for VMware Cloud on AWS and NSX-T |
| `VMC Policy based VPN` | VMware Cloud on AWS policy-based VPN sessions |
| `NSX-T Policy based VPN` | NSX-T policy-based VPN sessions |
| `NSX Policy based VPN` | NSX policy-based VPN sessions |

## vDefend Distributed Firewall Inactive Rules

VCF Operations for networks supports the visibility of the vDefend distributed firewall rules for which there have been no flows for some time. These rules are known as inactive rules. Such rules use memory heap and can cause security issues. To monitor these inactive rules, VCF Operations for networks provides the following two widgets in the **Security** dashboard:

**Note:**
To view the Security dashboard, enter **Security** in the search bar.

- Unused vDefend Firewall Rule: This widget lists all the NSX firewall rules where no flow is reported on the given time. You can also use the following search query to retrieve these rules:
  `nsx firewall rule where flow is not set`

  **Note:**

  Ensure that you have enabled vDefend Distributed Firewall IPFIX for the specified time.

## Fortinet Firewall

In VCF Operations for networks, you can view insight about Fortinet firewall.

VCF Operations for networks supports the following Fortinet entities -

- Fortinet Manager
- Fortinet ADOM - Fortinet Administrative Domain details
- Fortinet VDOM - Fortinet Virtual Domain details. VCF Operations for networks supports only Flow-based filtering is supported. Transparent mode is not supported.
- Fortinet Address - List of ADOM specific Addresses. VCF Operations for networks support ipmask, iprange, and NSX fabric connectors.
- Fortinet Address Groups - List of ADOM specific address groups
- Fortinet Dynamic Addresses - List of ADOM specific dynamic addresses (VDOM Mapped Addresses)
- Fortinet Dynamic Address Groups - List of ADOM specific dynamic address groups (VDOM Mapped Address Groups)

- Fortinet Dynamic Interfaces - List of ADOM specific dynamic interfaces.
- Fortinet Zones - List of ADOM specific zones.
- Fortinet Services - List of manual and auto generated services for each ADOM.
- Fortinet Service Groups - List of service groups for each ADOM.
- Fortinet Policy - Fortinet Policies for each ADOM. We currently support only IPv4 policies, Fortinet Global Header Policies, and Fortinet Global Footer policies.
- Fortinet Policy Packages - List of Policy packages. The policy packages name also contain the path to the policy package preceding the name of package.
- Fortinet Devices - List of Fortinet devices that are associated with the FortiManager.
- Fortinet Device Groups - List of Fortinet Device Groups specified by the user.

The followings are not supported:

- VM to VM path for physical devices in transparent mode.
- Advanced (non-IP based) policy properties like User, User Group, Application, and Security Profile.

## Export Firewall Rules by Running CLI Commands

You can export the firewall rules in VCF Operations for networks to a CSV file.

1. Log in to the VCF Operations for networks Platform CLI as a **Support** user.
   Provide your CLI login credentials using the SSH client.
2. Switch to a **Ubuntu** user.
   ```
   ub
   ```
3. Invoke the RDB tool.
   ```
   rdb
   ```
4. Export the firewall rules in VCF Operations for networks to a CSV file using the `run_fw_rule_export -p` command.
   ```
   run_fw_rule_export -p <new csv file with directory path>
   ```
   For example, run the following command to export all firewall rules to a file named `firewallRules_rdb.csv` file in the `tmp` directory:
   ```
   run_fw_rule_export -p /tmp/firewallRules_rdb.csv
   ```
5. Navigate to the directory in which you have saved the CSV file.
   ```
   cd /<directory path>
   ```
6. Change the owner and group of the CSV file to `support`.
   ```
   sudo chown support:support <file name>
   ```
   For example, run the following command to change the owner and group of the `firewallRules_rdb.csv` file to `support`:
   ```
   sudo chown support:support ./firewallRules_rdb.csv
   ```
7. Copy the CSV file to your local machine.
   For example, you can run the `scp` command to copy the CSV file to a mac machine.
   ```
   scp support@10.79.191.187:/tmp/firewallRules_rdb.csv ./
   ```
8. Open the CSV file on your local machine.
   An example CSV file with the firewall rules:

| A | B | C | D | E | F | G | H |
|---|---|---|---|---|---|---|---|
| Rule Name | Sequence | Manager | Entity Type | Firewall Type | Sources | Source Vms | Source SG Members |
| Default LR Layer3 | 1 | 10 | NSX-T Firewall Rule | Edge Firewall | Any | | |
| To_test_tenant2_ | 2 | 10 | NSX-T Firewall Rule | Edge Firewall | Any | | |
| default_blacklist_r | 3 | 10 | NSX-T Firewall Rule | Distributed Firewall | Any | | |
| direct-host-rule-in | 4 | 10 | NSX-T Firewall Rule | Distributed Firewall | Any | | |
| fw_VM2-ten2-hos | 5 | 10 | NSX-T Firewall Rule | Distributed Firewall | | | |
| direct-host-rule-ou | 6 | 10 | NSX-T Firewall Rule | Distributed Firewall | direct-host-ipset | | |
| TEST1 | 7 | 10 | NSX-T Firewall Rule | Distributed Firewall | Any | | |
| Between tenants p | 8 | 10 | NSX-T Firewall Rule | Distributed Firewall | Tenant_Two | | tenant2-ls |
| 16_Aug_Rule_with | 9 | 10 | NSX-T Firewall Rule | Distributed Firewall | IP_Of_VM-web-VM-1-Host-212 | | |
| 16_Aug_Rule2 | 10 | 10 | NSX-T Firewall Rule | Distributed Firewall | ls-app-tenant1 | app-VM1-host133 | |
| 16_Aug_Rule1 | 11 | 10 | NSX-T Firewall Rule | Distributed Firewall | ubuntu-133-2/ubuntu-133-2.vm | web-VM-3-host133 | |

# Working with Micro-Segmentation

VCF Operations for networks provides planning and recommendations for implementing the micro-segmentation security. It helps the user to manage and scale the VMware NSX deployments quickly and confidently.

## Analyzing the Application

The micro-segmentation planning topology shows all the flows that are present in your environment by dividing the flows into segments.

In VCF Operations for networks, a flow is a 4-tuple. It includes:

- Source IP
- Destination IP
- Destination port
- Protocol

You can view the data in two formats: Micro-segment wheel View and the Grid View

### Analyze Flow to Perform Security Planning

With **Security Planning**, you can analyze flows to view segmentations and traffic flow patterns in your environment for better security planning.

1. In the left navigation pane, click **Plan & Assess** > **Security Planning**.
   You see **Security Planning** window.
2. From the **Scope** drop-down menu, select one of the following options:

| Option | Action |
|---|---|
| **All flows** | Select to analyze all the flows available in your environment. |
| **Entities** | Select to analyze flows of a particular entity.<br>Click **Entities** and from the drop-down menu select the entity type.<br>You can also use the **Search entity by name** text box to find and select multiple entities.<br>When you click the **Search entity by name** text box, you can see the name of all the available entities for the selected entity type. |
| **Between entities** | Select to analyze flows between two entities.<br>1. From the **Entity type 1** drop-down menu, select an entity type. Also, you can use **Search entity by name** text box to enter the entities names.<br>You can enter multiple entities in the **Search entity by name** text box. |

| Option | Action |
|---|---|
| | 2. From the **Entity type 2** drop-down menu, select an entity type. Also, you can use **Search entity by name** text box to enter the entities names.<br>You can enter multiple entities in the **Search entity by name** text box. |
| **Flows matching properties** | Select to analyze flows that match a specific condition. You can add multiple conditions by clicking **ADD CONDITION**. |
| **Custom search** | Select to analyze flows that match a custom search query. |

3. From the **Duration** drop-down menu, select the time frame for which you want to analyze the flows. The system analyzes the flows that occurred between that specific time frame.
4. From the **Ports** drop-down menu, select one of the following:

| Option | Action |
|---|---|
| **All** | Select to analyze all ports available for the selected scope. |
| **Include Ports** | Select to include specific ports that you want to analyze. Enter the names of the ports that you want to analyze in the **Search Ports** text box. |
| **Exclude Ports** | Select to exclude specific ports that you do not want to analyze. Enter the names of the ports that you do not want to analyze in the **Search Ports** text box. |

   **Note:**
   If you have selected **Flows matching properties** and **Custom search** in **Scope**, you do not see **Ports** drop-down menu.

5. The **Group by** drop-down menu is auto-filled depending on what you select as **Scope**.
   If necessary, you can change the **Group by** by selecting appropriate option from drop-down menu.
6. Click **ANALYZE**.

## Viewing Micro-Segmentation And Flow Data in Wheel View

In the Segments Wheel view, the blue lines denote the outgoing flows, the yellow lines denote the incoming flows, and the green lines denote the flows that are bidirectional.

Click any of the segments to view its details, and to modify the scope, click **Modify Scope** in the top panel.

The VMs that are outside the selected scope are grouped as **Other Entities** in the micro-segmentation planning topology.

For better visibility and ease of use, you can only see 10 segments at a time. If you have more than 10 segments, then the extra segments are hidden under one large segment located next to **Other Entities**. To see the list of hidden segments point to the large segment next to **Other Entities** and you see the list of hidden segments.

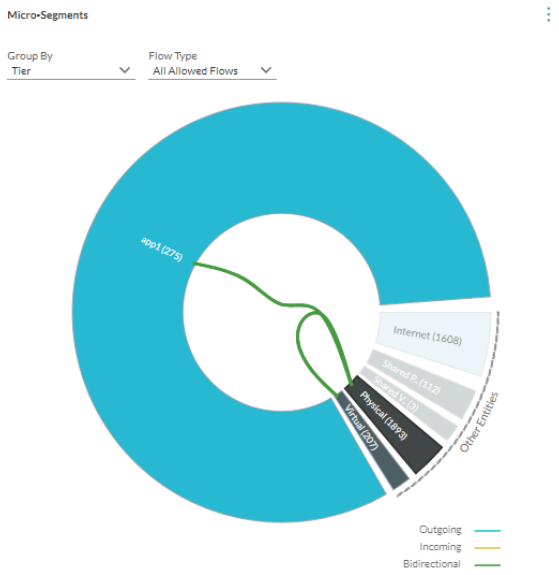
You can also hide the visible segments. To hide a segment point to the segment you want to hide, and click **HIDE**. To unhide a hidden segment, point to the large segment next to **Other Entities**, you see the list of hidden segments, click **SHOW** for the segment you want to unhide.

**Note:**
If you have more the 10 visible segments, then you can not unhide the hidden segments.

You can also analyze the flows by creating subgroups as per Physical, Other Virtual, and Internet categories.

| Group By | Also show groups for |
|---|---|
| VLAN/VXLAN | All |
| Application | Physical |
| ✓ Tier | Virtual |
| Subnet | Internet |
| Folder | ✓ None |
| Cluster | |
| VM | |
| Port | |
| Security Tag | |
| Security Group | |
| IPSet | |
| VPC | |

Each group is expanded into a wedge. In the following topology, the wedge for **Physical group** is seen.



The Flows pin shows that the flows for different time intervals separated by ports. You can either view all the flows or view the flows between two entities. You can filter the flows by Allowed and Blocked flows. You can view flows by either Total

Bytes or by Allowed Session Count. For the flows that are protected by a firewall, a Protected by Firewall sign is used to denote that the flows in that port that are protected by a firewall.

The planning for a scope such as an entire data center or a cluster selects flows that have VMs or Physical Servers (identified by the Physical IPs) as the source or the destination.

A topology has two distinct zones:

- Internal: This zone includes the VMs or the IP addresses in the scope.
- External: This zone includes the VMs or the IP addresses that are out of scope but talk to the VM or IP addresses in the internal zone. The external zone consists of the following wedges:
  - DC Virtual: It includes the source or the destination data center internal VMs that are talking to VMs or IP addresses in the internal zone and are not hosting any well-known shared services such as LDAP, NTP, and so on.
  - Shared Virtual: It includes the destination data center internal VMs hosting well-known shared services such as LDAP, NTP, and so on to which the VMs or IP addresses in the internal zone are talking.
  - DC Physical: It includes the source or the destination data center internal physical IP addresses that are talking to VMs or IP addresses in the internal zone and are not hosting any well-known shared services like LDAP, NTP, and so on.
  - Shared Physical: It includes the destination data center internal Physical IP addresses hosting well-known shared services such as LDAP, NTP, and so on to which the VMs or IP addresses in the internal zone are talking.
  - Internet: It includes the source or the destination data center external VMs or the physical IP addresses that are talking to the VMs or IP addresses in the internal zone.

**Note:**

- Data center Internal implies RFC 1918 designated IPs by default + any overrides defined in E-W settings.
- Data center External implies non-RFC 1918 designated IPs by default + any overrides defined in N-S settings.

## View Micro-segmentation And Flow Data in Grid View

VCF Operations for networks enables you to see the communication between objects in a tabular or grid view.

1. Navigate to **Security** > **Plan Security** and click

2. Select a value for **Group By** option, for example `VMs`, `Application`, `Security Groups` to see the corresponding details in the tabular format.

| Field Name | Description |
|---|---|
| Source Object | Name of the source |
| Destination Object | Name of the destination |
| Related Flows | Count of communication or flows between the source and destination<br>Click on the count value to see the related flow details. |
| Sum of Bytes | Aggregated number of bytes between all the flows |
| Max of Traffic Rate | Maximum traffic rate observed among all related flows |
| Count of Sessions | Number of active sessions for the particular flow |

**Note:**

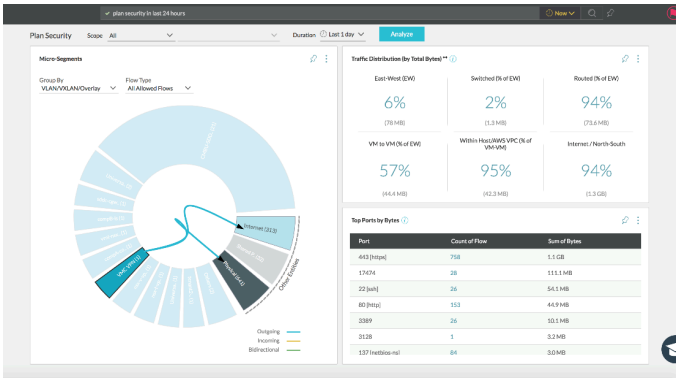
- You can click on each column header to sort the data in ascending or descending order.
- You can hide the field from the table view, click the more icon next on the field header and deselect the field name.

3. In addition, you can perform several actions on the grid view page.
   - In the filters pane on the left side of the screen, you can perform the following actions:
     - Select an individual source or destination to filter the flows that are related to selected source or destination object.
     - Select the firewall action to see the allowed flows or the dropped flows.
     - Select the protection status to see the flow status.
   - Click **Add more filters** to add additional filters.
   - To export the tabular data in a CSV format, click the more option on top of the table, and select **Export as CSV**.

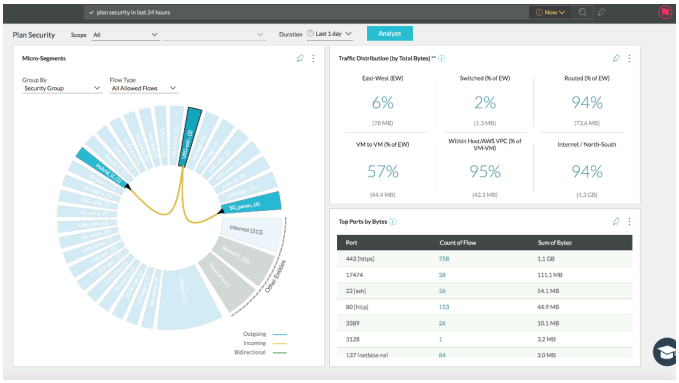
### VMware Cloud on AWS: Planning and Micro-Segmentation

You can plan for a specific VMware Cloud on AWS segment by selecting **VMC Segment** as the scope in the **Plan Security** page.

For the policy segments, use the `VLAN/VXLAN/Overlay` clause in the group.



For the policy groups, use the `Security Group` clause in the group.



## Working with Crown Jewel Analysis

In VCF Operations for networks, you can perform crown jewel analysis to identify possible lateral movement opportunities for an adversary based on existing flow paths between various entities in your network.

You can choose to add your most critical VMs and physical IPs as crown jewels. After you add crown jewels in VCF Operations for networks, you can analyze and view existing flow related information, relationships between the entities based on flows, number of entities directly connected to your crown jewels, total incoming traffic flow to your crown jewels, and so on.

## Add a Crown Jewel

When you add crown jewels in VCF Operations for networks, you can analyze and view existing flow related information, relationships between the entities based on flows, number of entities directly connected to your crown jewels, total incoming traffic flow to your crown jewels, and so on.

1. From left navigation page, click **Plan & Assess** > **Crown Jewel Analysis** > **Add Crown Jewels**.

   **Note:**
   If any crown jewels exist in your environment in VCF Operations for networks, then you can add crown jewels from the **Manage Crown Jewels** page.

2. In the **Add Crown Jewels** page, select VMs or IPs you want to add as crown jewels.

   You can add multiple VMs or IPs as crown jewels. You can add either VMs and IPs that are auto populated by the system or use the custom VM or the custom IP search to add VMs and IPs as crown jewels.

   **Note:**
   You can add up to 25 entities as crown jewels.

3. Click **Submit**.

You can Perform Crown Jewel Analysis or Managing Crown Jewels.

## Perform Crown Jewel Analysis

Perform crown jewel analysis to get insights about the possible reachability of your crown jewels due to lateral movements by an adversary. The reachability score gives an estimate of how far your crown jewels are from various entities and possibly how many lateral moves are required by an adversary to reach your crown jewels. Also, using crown jewels analysis, you get firewall rules suggestions to strengthen the security of your crown jewels assuming that the current state of flows is legitimate.

Verify that you have added at least one crown jewel in VCF Operations for networks.

1. From left navigation page, click **Plan & Assess** > **Crown Jewel Analysis**.
2. In the **Crown Jewel Analysis** window, select the crown jewels you want to analyze.

   **Note:**
   You can select up to 10 crown jewels for analysis.

3. Select **Scope** and **Duration** for your analysis.
4. Click **Analyze**.

The **Crown Jewels Analysis** page shows the total connected entities to the crown jewels, reachability score, incoming flows, total incoming traffic, and so on.

You can toggle between topology view and grid view. Click

to toggle between grid view and topology view.

The reachability score gives an estimate of how far your crown jewels are from various entities and possibly how many lateral moves are required by an adversary to reach your crown jewels. For example, reachability score one estimates that the crown jewel is one step away from the entities at node level 1.

You can also generate a PDF version of the analysis report. Click the **Generate VNA Report** to generate a PDF version of the analysis report.

## Managing Crown Jewels

You can add, delete, analyze crown jewels from the **Manage Crown Jewels** page.

In the **Manage Crown Jewels** page, you see a list of all crown jewels available in VCF Operations for networks. You can search crown jewels, add crown jewels, and preform crown jewel analysis from this page.

# Working with Applications

An application is a collection of tiers. Each tier in an application is a collection of VMs, Kubernetes services, and physical IPs.

You can create a group of tiers and visualize traffic or flows between:

- Applications
- Tiers of the same application
- Shared services
- Internet

You can create or add an application into VCF Operations for networks in three ways:

- Manually on the User Interface
- Public API
- Application Discovery

**Note:**

When you upgrade to VCF Operations for networks version 6.8, application alerts raised due to analytics threshold configuration are closed automatically. If the alerts persist, they are raised as intent alerts by the system after 24 hours of the upgrade.

## Create an Application Manually

You can manually create an application in the VCF Operations for networks user interface.

1. On the left navigation pane, click **Applications** > **Add Applications** > **Add Manually**.
2. In the **Application Name** text box, enter a name for the application you want to create.
3. In the **Tier/Deployment** section, enter a unique name.
4. In the **Member** field, perform the following steps:
   a) Select a condition from the drop-down menu to create a tier.

      You can define a condition based on any of the following properties:

      - VM properties
      - Location of VMs (application, cluster, folders).
      - Kubernetes services (service name, cluster IP address, namespace, cluster IP, or service labels).

      To learn more about the supported properties while defining a condition, see List of Supported Properties.

      To create tiers for the physical IPs based on enriched DNS, Subnet, or VLAN, see Creating Tiers for Physical IPs.

      To search a specific Kubernetes service that has the same name, same IP, or the same tag in multiple clusters, use custom search.
   b) Enter or select the value that you want to add to the tier.

      For entering multiple values, use comma after individual values.
5. Optional: To add another condition, click **Add another Condition**.
6. Optional: To create another tier under an application, click **Add Tier/Deployment**.

   You can create multiple tiers for an application.

   The application creates the tiers and shows the count of VMs, physical IPs, and Kubernetes services matching the conditions.
7. To receive alerts on intent violations, select the **Enable Application Aware Network Health Intents** check box.

   The system monitors the network health of the application and generates alerts if the application health intents are violated.

8. Optional: To preview the flow analysis, on the **Preview Micro-Segments** widget, click **Update view**.
   You see the micro-segment view for the application.
9. Click **Save**.

You can see the application listed on the **All Applications** page. To learn more, see Viewing All Applications .

### Creating Tiers for Physical IPs

While creating an application, you can select **Custom IP Search** from the drop-down list to create tiers for the physical IPs based on the enriched fields. For more information on the enriched fields, refer Enriching Flows and IP Endpoints.

The enriched DNS, Subnet, VLAN information can be used in specifying tiers as follows :

- Web
  `Query: IP Endpoint where Subnet Network = '172.16.101.0/24'`
- App
  `Query: IP Endpoint where Dns Domain = app.example.com`
- DB
  `Query: IP Endpoint where L2 Network = 'vlan-102'`
- Common Services
  `Query: IP Endpoint where Dns Domain = svc.example.com`

### List of Supported Properties

When creating or editing an application, VCF Operations for networks supports specific members.

The following lists shows the supported VM properties for VM members in VCF Operations for networks:

- AWS VPC
- Account
- Application
- Availability Zone
- Azure Application Security Group
- ASG Count
- Cluster
- DVPG
- Datacenter
- Folder
- Host
- IP Address
- IPSet
- IPSet count
- Incoming Port
- L2 Network
- NSGroup
- NSX
- NSX Manager
- NSX Policy Group
- NSX-T IPSet
- Name
- Network Address
- Operating System
- Other Names
- Outgoing Port
- Region

- Resource Pool
- SDDC
- SDDC Group
- Security Group
- Security Group Count
- Security Tag
- Subnet
- Subscription
- Tag
- Tag Key
- Tier
- VLAN
- VXLAN
- vCenter

The following lists shows the supported IP endpoint properties for IP endpoint members in VCF Operations for networks:

- Application
- IP Address
- Incoming port
- L2 Network
- Outgoing port
- Subnet Network
- Tier

The following lists shows the supported Kubernetes properties for Kubernetes services members in VCF Operations for networks:

- Cluster IP
- Cluster Network Address
- External IP
- External Network Address
- Kubernetes Cluster
- Kubernetes Namespace
- Label
- LoadBalancer IP
- LoadBalancer Network Address
- Name
- Node Port
- Port
- Port Name
- Selectors
- Target Port
- Type

## Working with Application Discovery

When you have several applications or when you have multiple tiers in an application, creating applications using the public APIs or the user interface becomes a long process. VCF Operations for networks auto-discovers applications and tiers and enables you to add them automatically, which reduces a lot of manual effort.

In VCF Operations for networks, you can discover applications based on:

- Flows
- VM Attributes (Names, Tags, Security Tags and Security Groups)
- ServiceNow

- Add Manually

  **An example of the application discovery construct by VM Attributes**

  You can discover application using VM Attributes which includes Names, Tags, Security Tags and Security Groups.

  Consider a scenario where you have:

  - Added VMware vCenter server as a data source.
  - Added four VMs in your data center - VM1, VM2, VM3, and VM4.
  - Defined tags (key-value) that defines the application names to which each VMs belong.
  - Defined tags (key-value) that defines the tier to which each VMs belong.

  For example, see the table:

| VM Name | Key-value tags |
|---|---|
| VM1 | • Application Name: MyApplication1<br>• Application Tier: App |
| VM2 | • Application Name: MyApplication1<br>• Application Tier: Web |
| VM3 | • Application Name: MyApplication2<br>• Application Tier: App |
| VM4 | • Application Name: MyApplication2<br>• Application Tier: Web |

**Discovering Applications based on VM Attributes (Tags)**

VCF Operations for networks, you can define a grouping criteria for application discovery for these tags.

> **Note:**
>
> In VCF Operations for networks, NSX tags are displayed as VM tags. Therefore, by default, NSX tags are also supported in application discovery.

In this example, based on the defined tags and grouping criteria, VCF Operations for networks discovers two applications (MyApplication1 and MyApplication2) with two tiers (App and Web) and its related VMs.

| Application | Tier | VM |
|---|---|---|
| MyApplication1 | App | VM1 |
| MyApplication1 | Web | VM2 |
| MyApplication2 | App | VM3 |
| MyApplication2 | Web | VM4 |

**Discovering Applications and Tiers based on VM Attributes (VM Names)**

If the VM names are defined in the following format:

```
ApplicationName : Tier : VMName.
```

For example,

```
MyApplication1 : App : VM1
MyApplication1 : Web : VM2
MyApplication2 : App : VM3
MyApplication2 : Web : VM4
```

When you use the following regular expression (regex), VCF Operations for networks discovers two applications.

- App Regex: `(.*)_(.*)_.*-.*`

- Tier Regex: `(.*)_(.*)_(.*)-.*`

| Application | Tiers and its VMs |
|---|---|
| MyApplication1 | • App and MyApplication1 : App : VM1<br>• Web and MyApplication1 : Web : VM2 |
| MyApplication2 | • App and MyApplication2 : App : VM3<br>• Web and MyApplication2 : Web : VM4 |

**Note:**

Inconsistently defined VM names cannot be grouped for application discovery.

**Discovering Applications Based on Flows**

VCF Operations for networks uses machine learning and statistical analysis to discover applications automatically and group the VMs into their respective applications and tiers. VCF Operations for networks analyzes the network flow between the VMs and groups the VMs by identifying the application and the tier boundaries between these VMs.

The system analyzes the flows on multiple dimensions such as density of the flows between VMs, common open ports between VMs, number of incoming against outgoing connections, configuration data from load balancers, and so on, and groups VMs with high similarity across these dimensions into a unique application. The process repeats again, but only among the VMs that are already grouped into an application, and to group VMs into their respective tiers.

**Note:**

- To discover applications based on flows, you must match the following minimum requirements:
  - Have at least 10 VMs discovered in VCF Operations for networks.
  - Have at least 100 VM-VM flows.
  - Use a platform of XL brick size.
  - To learn about the configuration requirements, see System Recommendations and Requirements.
  - If your configuration does not meet the minimum system requirement, you can either scale up your platform cluster or reconfigure your brick size. To learn about how to scale up the platform cluster, see Expand or Scale Out Clusters. To learn about reconfiguring the brick size, see KB 83374.

  To improve the accuracy of flow-based application discovery, you must add load balancers to VCF Operations for networks. To learn about the supported load balancers, see Supported Load Balancers.

In addition to VCF Operations for networks, you can perform flow-based application discovery from VCF Operations by navigating to **Infrastructure Operations** > **Analyze** and selecting the **Flows** tab.

**Discovering Applications Based on Flows by Uploading a CSV File**

In VCF Operations for networks, you can use the Discovery Options feature to upload a CSV file to discover applications. The CSV file can either be exported from the Configuration Management Data Base (CMDB) or manually created from other tools to improve the Flow based application and tier discovery. The inputs of the CSV file are verified using the Flow based application discovery algorithm and then used to discover applications. The uploaded CSV file can also be used to name applications and tiers.

This feature can enhance the discovery of applications where only some of the application definitions are known, and the application definitions may not be completely accurate. Flow based application discovery can still add VMs or remove VMs using the inputs of the CSV file depending on the actual Flow pattern at the time of discovery.

## Discover Applications

You can discover existing applications based on tags, ServiceNow, names, flows, and advanced properties, and add them into VCF Operations for networks.

1. To discover existing applications in your environment, from the left navigation panel, click **Applications** > **Add Applications**
2. You can discover applications in multiple ways. Select the preferred tab and perform the related steps.

| Tab | Description |
|---|---|
| **Flows** | Use flow based application discovery if you want to discover applications by analyzing the traffic patterns and network flows in your environment.<br>Flow based application discovery is automated and does not require any user input to start the discovery.<br>To learn more, see Discover Applications using Flows. |
| **VM Attributes** | Use VM Attributes based application discovery if your VMs follow a logical naming pattern, or if you have added tags for virtual machines in your VMware vCenter, Azure, AWS, or VMware NSX environments, or if you want to discover applications using a combination of VM names, security groups, tags from VMware vCenter, Azure, AWS, or VMware NSX environments.<br>To learn more, see Discover Applications using Names. |
| **ServiceNow** | Use ServiceNow based application discovery if you have mapped your applications in ServiceNow.<br>To learn more, see Discover Applications using ServiceNow. |
| **Add Manually** | Use add manually to create an application manually by adding tiers and members.<br>To learn more, see Create an Application Manually . |

**Note:**
The following limitations apply when discovering applications in VCF Operations for networks:

| Objects | Maximum limit | Impact if the limit exceeds |
|---|---|---|
| Applications on the map view | 1000 | Applications are not displayed on the map view. |
| Applications on the tabular view | 3000 | Only 3000 applications are displayed on the table view. |
| Saved applications | 10k | You cannot add a new application. |
| Total tiers across applications | 30k | You cannot add a new tier. |
| Tiers per application | 150 | You cannot add a new tier. |
| Members per tier | 5k | You cannot add a new tier. You can only update the existing applications to reduce tiers and members. |
| Members per application | 5k | The application page does not show any useful information such as microsegmentation, metrics, and analytics. To gain complete visibility of the application, you must reduce the application members. Also, VCF Operations for networks raises the following alert:`Application Membership limit exceeded`. |
| Flows per application | 500k | The application topology does not load on the respective application page. |

### Discover Applications using Flows

In VCF Operations for networks, you can discover applications based on flows.

Flow based application discovery uses machine learning algorithms to auto-discover your applications and application boundaries by analyzing the traffic patterns and network flows in your environment. To learn how to discover applications based on flows, see Discovering Applications Based on Flows.

You can also use flow based application discovery by adding applications from VCF Operations by navigating to **Operate** > **Workloads** > **Business Applications** and selecting **Add Applications** > **Based on Flows**.

1. From the left navigation panel, go to **Add Applications** > **Flows**.

   You see all the available applications based on flows. You also see application boundaries and tier boundaries between VMs based on the network flow communication between the VMs.

2. To modify the scope and the naming preference, click **Edit Discovery** and select the duration and the scope of application discovery.

   To learn more about modifying the scope, see Modify Application Scope.

3. To upload a CSV file with pre-existing application definitions, click **Discovery Options**.
   a) Click **Browse** and upload the CSV file.

      The CSV file must have the VM to application name, and the tier name mapping, as the same file is used for application and tier naming.

      **Note:**
      You can also provide regular expressions in the `VM Name` column of the CSV file. For example, to identify all the VM names starting with `MySQL-` for an application, you can provide `MySQL-.*` as the VM name.

   b) Click **Next**.

      VCF Operations for networks validates the uploaded CSV file and shows any missing information as an error followed by a table that lists the information that is missing with the respective row numbers. You can also export the missing information table as a CSV file.

4. Select the naming preference and the order in which you want to name applications and tiers. To learn more, see Set up Application and Tier Naming Preference.

   **Note:**
   VCF Operations for networks recommends the use of naming preferences to create logical and meaningful names for your applications and tiers.

5. Click **Submit**.

6. To pause or stop the auto discovery of flows on the **Discover Applications** page, click the **More Options** icon next to **Edit Discovery**, and select **Pause discovery** or **Stop discovery**.

   **Note:**

   If you click **Stop discovery**, you loose all the discovered applications.

7. Click **Granularity** to group the discovered applications at various levels based on number of tiers and VMs. You can select one of the following **Granularity** levels:

   - **Coarse**: The application group includes more tiers and VMs.
   - **Medium**: The application group includes less tiers and VMs.
   - **Fine**: The application group includes much fewer tiers and VMs.

   In the tabular view of discovered applications, you can see the **Confidence** column which describes the accuracy level of the application grouping. High confidence level indicates that the grouping accuracy is high and requires less user intervention.

View the applications discovered using flows. To learn more, see Viewing Discovered Applications.

### Discover Applications using Tags

You can perform tag based application discovery if you have added tags for virtual machines in your VMware vCenter, Azure, AWS, or VMware NSX environments.

Add tags for virtual machines in your VMware vCenter, Azure, AWS, or VMware NSX environments. To learn how to discover applications based on tags, see Discovering Applications based on VM Attributes (Tags).

1. From the left navigation panel, go to **Applications** > **Discover**.
2. Select the **Tags** tab.
3. Define the scope based on which applications and tiers have to be discovered.
   - Select **All VMs** to see a list of all VMs from all the data sources that are added in VCF Operations for networks.
   - Select **Manual Selection** and filter the VMs based on your requirements such as account, data center, manager, and so on.

     For example, this query limits the discovery of applications to specific regions:

     ```
     VMs where Region in ( 'Central US' , 'East US' )
     ```
4. Group applications using the key-value combination of tags.
   a) Enter a key for the tag.
   b) Optional: Enter a value for the respective key.

   For example, if you enter the key as `Department` and select **Any Value**, VCF Operations for networks will create application boundaries based on all values of the `Department` tag.
5. Group application tiers using the key-value combination of tags.
   a) Enter a key for the tag.
   b) Optional: Enter a value for the respective key.

   For example, if you enter the key as `Role` and select **Any Value**, VCF Operations for networks will create distinct tiers of an application based on all values of the `Role` tag.
6. Optional: Click **Found *count* Applications** to see the list of application names, the VM names and the number of VMs that matches the specified criteria.
7. Optional: Click **Unclassified VMs** to see a list of VMware vCenter, AWS, or Azure VMs that are not following the specified name pattern or tag pattern. You can edit these VMs on the respective environments to fix the name or the tag criteria.
8. Optional: Select the **Save changes to** option to create a template or update an existing template.

   **Note:**
   If you are an admin user, you can update all templates. If you are a member user, you can only edit the templates that you had created.
9. Click **Discover**.

You see the tabular and the hexagonal map view of all applications that matches the criteria.

View the applications discovered by tags. To learn more, see Viewing Discovered Applications.

**Discover Applications using Names**
You can perform name based application discovery if your VMs and Kubernetes services follow logical naming patterns.

Add logical naming patterns to virtual machines in your VMware vCenter, Azure, AWS, or VMware NSX environments.To learn how to discover applications and tiers based on names, see Discovering Applications and Tiers based on VM Attributes (VM Names).

1. From the left navigation panel, go to **Applications** > **Discover**.
2. Select the **Names** tab.
3. Optional: If you have already defined a template using which you want to perform application discovery, select the template from the **App discovery templates** drop-down menu. The application discovery starts automatically.
4. Define the scope based on which you want to discover applications and tiers.
   - Select **All VMs** to see a list of all VMs from all the data sources that are added in VCF Operations for networks.

- Select **Manual Selection** and filter the VMs based on the your requirement like account, datacenter, manager, and so on.

  For example, this query limits the discovery of applications to specific regions:

  ```
  VMs where Region in ( 'Central US' , 'East US' )
  ```

5. Group applications by VM names using regular expressions based pattern matching.
   - Enter a regular expression of your choice.
   - Select **Pattern Builder** or **Advanced** to manually enter a Regular Expression.
     a. Select the reference VM name or select a VM from the list to build a pattern or the regular expression based on the VM name.
     b. Click a position or a group to construct a pattern.

     **Note:**

     After selecting a group, if you select a character or position, VCF Operations for networks ignores your group selection for building the pattern and vice versa.

     Based on your selections, you see the pattern appearing on the screen. And also, you see the list of applications that match the pattern and the count of VMs in the respective applications and the VM names in the respective applications..
     c. Click **Submit**.
6. Optional: Click **Found *count* Applications** see the list of application names, VM names, and the number of VMs that matches the regular expression.
7. Optional: Click **Unclassified VMs** to see a list of VMs that are not following the specified name pattern.
8. Optional: Select the **Save changes to** option to create a template or update an existing template.

   **Note:**
   If you are an admin user, you can update all templates. If you are a member user, you can only edit the templates that you had created.
9. Click **Discover**.

View the applications discovered by names. To learn more, see Viewing Discovered Applications.

**Discover Applications using ServiceNow**
You can perform application discovery based on ServiceNow if you have mapped your applications in the ServiceNow data source that is added to VCF Operations for networks.

You must have added ServiceNow as a data source in VCF Operations for networks.

1. From the left navigation panel, go to **Applications** > **Discover**.
2. Select the **ServiceNow** tab.

You see the applications available on ServiceNow.

View the applications discovered from ServiceNow. To learn more, see Viewing Discovered Applications.

When working with ServiceNow, be aware of the following limitations:

- SNOW app discovery count is limited to now more than 5K apps.
- Traffic, Tag, and ML-based apps are not discovered.
- If there is no dependency map for the SNOW app, it is not discovered.
- If the VMs on which apps run are deleted or the relevant vCenter instance is not added in VCF Operations for networks, the apps are not discovered.
- VCF Operations for networks does not support button-to-top discovery.

**Discover Applications using Advanced Properties**
You can perform an advanced application discovery to discover applications using a combination of VM names and security group tags from your VMware vCenter, Azure, AWS, and NSX environments.

1. From the left navigation panel, go to **Application** > **Add Applications**.
2. Select the **Advanced** tab.
3. Optional: If you have already defined a template using which you want to perform application discovery, select the template from the **App discovery templates** drop-down menu. The application discovery starts automatically.
4. Define the scope based on which you want to discover applications and tiers.
   - Select **All VMs** to see a list of all VMs from all the data sources that are added in VCF Operations for networks.
   - Select **Manual Selection** and filter the VMs based on your requirement like account, data center, manager, and so on.

     For example, this query limits the discovery of applications to specific regions:

     ```
     VMs where Region in ( 'Central US' , 'East US' )
     ```
5. Group applications by different VM properties using regular expressions based pattern matching.
   - Enter a regular expression of your choice.
   - Click **Pattern Builder** to define patterns using groups or position of characters in strings.
     a. To build a pattern or the regular expression based on the VM name, select the default VM name or select a VM from the list.
     b. Click on a position or a group to construct a pattern.

     **Note:**

     After selecting a group, if you select a character or position, VCF Operations for networks ignores your group selection for building the pattern and vice versa.

     Based on your selections, you see the pattern appearing on the screen. You also see the list of applications that match the pattern, the count of VMs in the respective applications, and the VM names in the respective applications.
     c. Click **Submit**.
6. Optional: Click **Found *count* Applications** to see the list of application names, VM names, and the number of VMs that matches the regular expression.
7. Optional: Click **Unclassified VMs** to see a list of VMs that are not following the specified name pattern.
8. Optional: Select **Save changes to** to create a template or update an existing template.

   **Note:**
   If you are an admin user, you can update all templates. If you are a member user, you can only edit the templates that you had created.
9. Click **Discover**.

View the discovered applications. To learn more, see Viewing Discovered Applications.

## Viewing Discovered Applications

When you perform application discovery using tags, names, ServiceNow, flows, or advanced properties, VCF Operations for networks displays the discovered applications that match the criteria in a tabular view and a map view.

The map and the tabular view are interactive. If you click an application in the tabular view, the hexagon representing the application gets highlighted or focused on the map view, displaying shared services and network connections with other applications.

### Tabular View of Applications

In the tabular view, you can do the following:

- View details such as the application name, count of tiers and VMs, and status. If you discover applications using flows, you also see the **Confidence** column indicating the accuracy of discovered applications.

- Click the **Save** icon next to the application to save the application.
- Select one or more applications and click the **Actions** drop-down menu to save selected applications.
- Select one or more applications and click the **Actions** drop-down menu to merge or save applications.
  Select two or more applications, click the **Actions** drop-down menu, and select the **Merge & Save** option to merge selected applications and save them as a single application. You do this action only if your application is discovered as multiple applications and you want to merge them back to a single application.

  **Note:**
  You can merge a maximum of 20 applications.
- If you discover applications using ServiceNow or flows, you can export one or more applications in `.csv` format.

**Map View of Applications**

In the map view, you can do the following:

- Hover over a hexagon to see details such as the application name, discovered VM count, and the tier count.
- On hover, click **Save Application** to save the application.
- Zoom in and zoom out, or move the map to see the applications.
- See applications with unprotected flows.
- See applications talking to the internet.
- See applications using shared services.
- See applications with problems.

**Viewing Discovered Applications by Criteria**

Use the following options that are available on the top of the page to sort, filter, and search discovered applications:

| Option | Description |
|---|---|
| **Granularity** | Displays applications based on size. Fine granularity displays smaller applications and coarse granularity displays only larger applications.<br>**Note:**<br>You see this option only if you have discovered applications using flows. |
| **Sort by** | Sorts applications by name, tiers, and VMs.<br>If you have discovered applications using flows, you can also sort your applications by **Confidence**. |
| **Show** | Displays top 10, 20, 50, or 100 applications on the map and the table view. |
| Search apps, tiers, or VMs | Searches applications by name, tiers, or members. |

## Save Discovered Applications

When you perform an application discovery using tags, names, ServiceNow, flows, or advanced properties, VCF Operations for networks displays all the discovered applications that match the criteria in a table view and a map view. You can save one or more applications from the map view or the table view.

Ensure you have already discovered applications in VCF Operations for networks.

You can choose to save a single application, or save multiple applications in the tabular view.

1. Select the applications you want to save.
   - On the tabular view, select **SAVE** next to the application that you want to save.
   - On the tabular view, select the application that you want to save and click **ACTIONS** > **SAVE**.

- To save multiple applications, on the tabular view, select the check box next to the applications you want to save and click **ACTIONS** > **SAVE**.
- On the map view, hover the mouse on a hexagon and click **Save Application**.

2. In the **Save Application** window, validate the information or modify the existing information such as application name, tier name, or tier members.
3. If you modify the members of the tier, click **Update view** to update the view and analyse the latest flows.

   The micro-segmentation wheel shows the updated view of the application.
4. Click **Save**.

View details of the application by navigating to the application page. To learn more, see Viewing Application Details.

Or, click **Actions** > **Export as CSV** to export the application details in the `.csv` format.

You can define the application count and the fields that you want to export. The application name and the tier name fields are repeated based on the member count (one row per member). The fields that are irrelevant to the application are left empty.

> **Note:**
> You can export the details of applications discovered through flows and ServiceNow to the `.csv` format without saving the applications.

## Merge Discovered Applications

In VCF Operations for networks, you can merge multiple discovered applications into one or more applications. You can merge applications if VCF Operations for networks discovers an application as multiple smaller applications.

Ensure you have already discovered applications in VCF Operations for networks.

1. In the **Discover** tab, from the applications list table, select the applications that you want to merge, and click **ACTIONS** > **Merge & Save**.
2. In the **Merge & Save Applications** window, in the **Application Name** text box, provide a unique name for the application.

   In this page, you can see the application summary which includes the number of tiers, VMs, physical IPs, and services. Also, you see the name of the applications that you are merging.
3. Review the Tier / Deployment details. If needed, you can rename the tiers.

   The application tiers are created based on the number of tiers available in the original applications that you are merging. For example, if you are merging two applications which have one tier each, then in the **Merge & Save Applications** window, you see two tiers. And the system creates a default name for tiers by combining the original application name and tier name. For example, if you are merging two applications, named: App1 and App2, and each of the application consists of one tier, named t1 and t2 respectively. The in the merged application, you see two tiers, named App1_t1 and App2_t2.
4. Deselect the **Enable Application Aware Network Health Intents** check box if you do not want to receive intent based alerts for this application.

   By default, this check box is selected.
5. Optional: To preview the flow analysis, click **Update view** in the **Preview Micro-Segments** widget.
6. Click **Save**.
7. To exit the **Merge & Save Applications** window, click **Cancel**.

## Set up Application and Tier Naming Preference

When you are performing flow-based application discovery, VCF Operations for networks provides options to set up the naming preference and allows you to choose the order of naming your applications and tiers. Setting up naming preferences helps you create logical and meaningful names for your applications and tiers.

By default, VCF Operations for networks names applications and tiers based on the names of the VMs that are part of applications and tiers. If the VM names do not reflect the application or tier then application and tier names do not help you to find the actual applications or tiers.

Therefore, when you perform flow-based application discovery, you can set the naming preference for your applications and tiers. You can also activate or deactive naming preferences, and choose the order of naming the applications and tiers. VCF Operations for networks automatically renames the existing applications and tiers, and names the newly discovered applications and tiers, as per your set naming preference and order.

**Procedure**

1. On the **Discover Applications** page, in the **Scope** bar of the **Flows** tab, click **Edit Discovery**.
2. In the **Edit Discovery** window, click **Application and Tier Naming**.
3. Select the naming preference you want to add.
   You can select one or more of the following naming preferences and arrange them in the order they must be considered:
   - Upload CSV
   - Security tags
   - Security groups
   - Load balancer
   - VM names
   - VM tags

   To arrange the order of the naming preferences, you must use the drag icon.
   VCF Operations for networks renames your applications based on the preferences and the order you select. You can see how your selection changes the application names in the **Tip** section.
4. If you are naming your applications and tiers based on VM names, you can also use regular expressions. You can select the **Regex** option in the **Status** column of **VM Names**, and in the **Application Naming** and **Tier Naming** sections, do one of the following:
   – Select **Regex** and provide a regular expression using which you want to name your applications and tiers.
   – Click **Pattern Builder**, select a sample VM to identify the pattern, choose the position of characters or groups to create the pattern, and click **Submit**.
5. When you select the **Upload CSV** option, the names of VMs, applications, and tiers are taken from the CSV file that was uploaded while discovering applications based on flows.
6. Click **SUBMIT**.

If applications or tiers do not match your selected naming preference, then the system renames applications or tiers based on the VM names.

## Modify Application Scope

By default, VCF Operations for networks analyzes flows for a period of seven days to discover flow based applications. If you want to change the default preference, then you can change the duration and scope of the discovery as per your requirement.

1. On the **Discover Applications** page, in the **Scope** bar of the **Flows** tab, click **Edit Discovery**.
2. In the **Edit Discovery** window, select **Discovery Scope**.
3. From the **Scope** drop-down menu, select your preferred scope. If you want to discover applications based on entities, select **Entities** from the drop-down menu, select an entity type, and provide the entity names.
4. From the **Duration** drop-down menu, select your preferred duration.
5. Click **Submit**.

### Update Application Membership

When VCF Operations for networks detects any changes in the membership of a saved application, it prompts you to update the application.

For flow based application discovery and ServiceNow auto-discovery, VCF Operations for networks discovers and updates applications periodically. If VCF Operations for networks detects any updates or changes in the membership of the saved applications, then you see an **Update available** button on the application for which an update is available. You can update the applications one by one or you can bulk update all the applications for which an update is available.

1. In the **All Applications** > **List** tab, click the **Update available** button next to the application that is having membership changes.
2. In the **Update Application** dialog box, review the changes, and click **Update**.
3. To bulk update multiple application, click the **Update All** button located above the application list.

### Troubleshooting Application Discovery Related Errors

The table lists errors you might encounter while working **Applications** with the cause and resolution steps.

| Error Text | Cause | Resolution |
|---|---|---|
| `The current cluster configuration does not support flow based application discovery (FBAD).` | Your platform does not meet the minimum system requirements. | You must the expand cluster. See Expand or Scale Out Clusters. |
| `The current cluster configuration does not support application discovery due to the large number of VM to VM flows or VMs.` | Your current cluster configuration cannot handle the total numbers of VMs and VM to VM flows. | You must reduce the scope or reconfigure your cluster to support the large number of VMs and VM to VM paths.<br>To learn how to reconfigure clusters, see KB 83347.<br>To learn how to expand clusters, see Expand or Scale Out Clusters.<br>. |

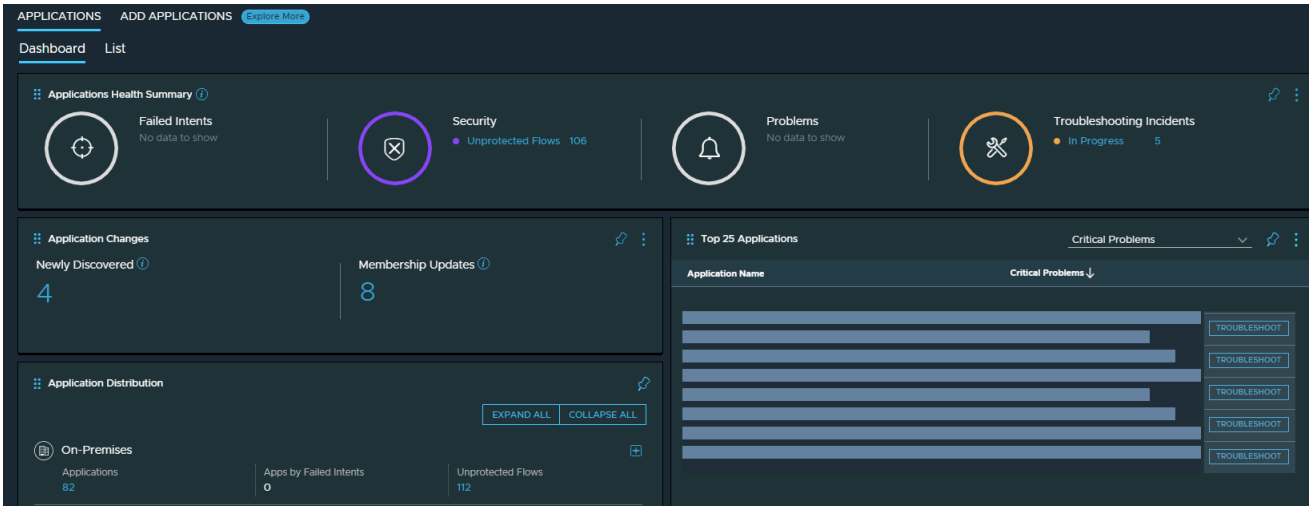
## Viewing All Applications

The **Applications** page provides an end-to-end visibility of applications in VCF Operations for networks.

To access the **Applications** page, from the navigation pane, go to **Applications**.

On this page, you can:

- View the overall health of applications.
- View applications categorized by different alerts
- Start one or more troubleshooting incidents
- Click the **Discover** button to perform application discovery
- Click the **Add** button to add applications manually.



## Dashboard Tab

The dashboard tab provides a complete overview of applications in VCF Operations for networks. The following table describes different elements of the tab:

| Elements | Description |
|---|---|
| **Applications Health Summary** | Shows applications grouped by alerts, security, failed intents, and troubleshooting incidents. To learn more or troubleshoot issues, click the actionable information within the widget. |
| **Application Changes** | Shows applications modified in the last 24 hours. You can:<br>• Click the number associated with **Newly Discovered** to view and save newly discovered applications.<br>• Click the number associated with **Membership Updates** to view and update applications having membership changes. |
| **Application Distribution** | Shows applications grouped by on-premises, cloud, and hybrid environments. You can expand each section to view details such as failed intents and unprotected flows. |
| **Top 25 Applications** | Displays the top 25 applications based on:<br>• Critical problems<br>• Outgoing traffic<br>• Incoming traffic<br>• Failed intents<br>• Retransmission rate<br>• Round trip time<br>• Traffic from internet<br>• Traffic to internet<br>You can click an application to open the respective application page.<br>If you are viewing the top 25 applications based on critical problems, or intent violations, you can click the **Troubleshoot** button next to the application to start a troubleshooting incident. |

## List Tab

The list tab displays applications in a table and a map view.

The map and the tabular view are interactive. If you click an application in the tabular view, the hexagon representing the application gets highlighted or focused on the map view, displaying shared services and network connections with other applications.

| View | Description |
|---|---|
| **Table** | The tabular view displays details such as application name, count of members, count of tiers and updated at.<br>You can do the following:<br>• Hover the mouse on the value in the **Members** column to see the individual count of VMs, physical IPs, and services.<br>• Click an application to open the respective application page and view the details of that application.<br>To learn more, see Viewing Application Details.<br>• Update all applications by clicking the **Update All** button on top of the table view.<br>• Edit or delete an application by clicking respective icons next to the application.<br>• Select one or more applications to delete or export in the `.csv` format.<br>• Update applications individually by clicking the **Update Available** button next to the application.<br>To learn more, see Update Application Membership. |
| **Map** | On the map view, you can:<br>• Hover over a hexagon to see application details such as name, discovered VM count, and the tier count.<br>• On hover, click **View Details** to open the respective application page.<br>• Zoom in or zoom out of map by clicking the (+) or the (-) button.<br>• View applications with unprotected flows and problems.<br>• View applications talking to the internet.<br>• View applications using shared services.<br>• Click the lines connecting an application to the internet to view flow details such as:<br>– Count of source and destination flows<br>– Count of unprotected source flows<br>– Count of unprotected destination flows<br>**Note:**<br>If there are no flows or members associated with the application, a question mark is displayed on the hexagon. |

## Viewing Application Details

The application page provides a complete visibility of an application in VCF Operations for networks. The application page also allows you to troubleshoot problems and view analytics.

To view the details of an application, from the navigation pane, go to **Applications** > **List** and select an application from the list.

The following table describes different components of the application page:

| Component | Description |
|---|---|
| **Overview** | You see the overview of the application which includes:<br>• The application summary which provides information about alerts, incoming and outgoing traffic, flows, intents associated with the application, countries associated with the application, VMs, physical IPs, Kubernetes services counts, and so on.<br>• The **Application Topology** which displays the end-to-end interactive topology map of your application.<br>• Alerts related to the application.<br>• **Application Members Manager** which manages entities (such as VMware vCenter and NSX) for all application members. |
| **What's New** | • You see what's new in the last 24 hours which includes:<br>— Incoming and outgoing traffic count<br>— Dropped flows<br>— Analytics alerts<br>— New members<br>— New unprotected members<br>• External services accessed by the application in the last 24 hours.<br>• Services accessed by the application using the internet in the last 24 hours.<br>• Application ports used in the last 24 hours. |
| **Metric** | You see the following metrics:<br>• VM metric information that represents network rate, CPU, memory, and disk information.<br>• Kubernetes metrics |
| **Flows** | You see the following traffic flows or flow analytics associated with the application in the last 24 hours:<br>• Top talkers by flows<br>• Top application flows by rule<br>• Top incoming traffic by App-Id<br>• Top outgoing traffic by App-Id |
| **Microsegmentation** | You see:<br>• Contextual flows between entities, which provides data of different flow types such as all allowed and dropped flows, protected and unprotected flows by vDefend Distributed Firewall.<br>• What's new in the last 24 hours |
| **Intents** | You see the following options from the drop-down menu:<br>• **Intent Definitions**: Displays the metrics that are monitored to verify whether the conditions defined in the intents are met for the application.<br>• **Intent Violations**: Displays the intent violation alerts associated with the application. |

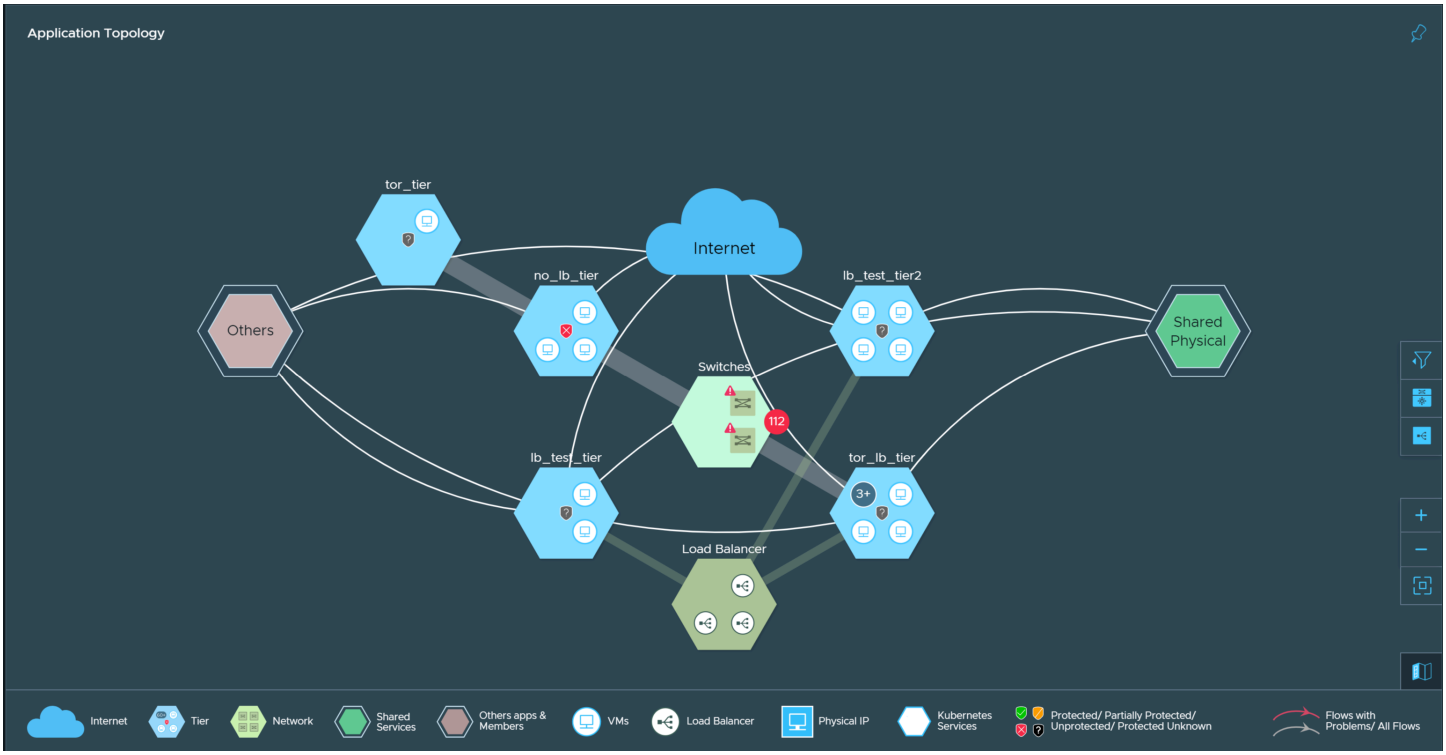
To start a troubleshooting incident from the application page, click the **Troubleshoot** button on the top right corner of the application dashboard.

Click the vertical ellipsis next to the **Troubleshoot** button to modify the application or export to PDF.

## Application Topology Map

The application topology map is shown on the Overview tab. It displays the traffic or the flows between the tiers of the same application and between applications.

- Tier overview
- List of members of the application (VMs, Kubernetes services, and physical IPs).
- Flows between tiers, internet, and shared services.
- The physical IPs that the application depends on or uses.
- Shared services
- Other applications with which this application talks to.
- List of load balancers in the application.



In the application topology map, hexagons represent tiers, load balancers, switches, shared services, and other network entities. You can hover over the hexagon and click **View Details** to view the details of that network entity.

The thin lines that run between two hexagons represent the flows between those two network entities. You can click anywhere on the flow to view details such as service endpoints of the flows, total traffic of the flow, and so on.

Similarly, if the virtual machines of a tier are configured behind one or more load balancers, you can select the thick lines that runs between the load balancer hexagon and the tier hexagon to view the details of virtual services, pools, and flows that are shared between that tier and the load balancers.

You can click the **Pin widget** icon at the upper-right corner of the topology map to either pin this topology map to an existing dashboard, or create a dashboard.

You can use the filter and the zoom options at the lower-right corner of the topology map to:

- View all flows, unprotected flows, or only degraded flows in the topology.
- Show or hide the switches associated with the application.
- Show or hide the load balancers associated with the application.
- Zoom in or zoom out of map
- Rearrange the map to fit the current screen
- Show or hide the legend which indicates the representation of each icon in the application topology.

## Working with Analytics

In VCF Operations for networks, using **Analytics**, you can detect outliers, configure threshold, and get flow analytics.

# Viewing Flow Insight Details

The **Flow Insights** page provides an insight into data centers, devices, and flows. It is a context-based page as it performs analysis based on the entities, flows, and the time range that you select.

To access the Flow Insight page, see Access Flow Insight page.

Alternatively, you can search for `Flows` and in the search result page, click **Flow Insight**.

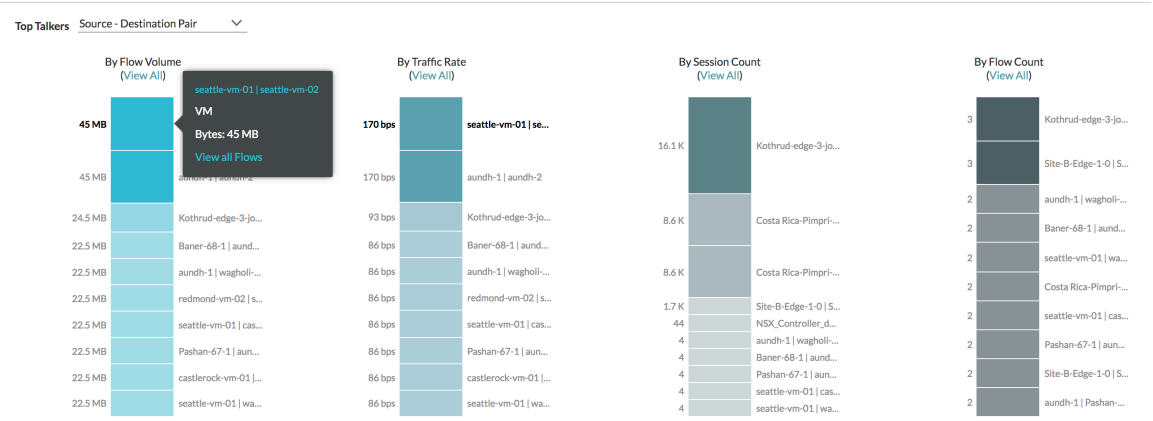
The various sections in the Flow Analytics Dashboard are:

- Top Talkers
- What's New
- Network Performance
- Outliers

## Top Talkers

This section helps you to recognize which entities are talking the most in your environment. You can select different kinds of entities such as Source-Destination pair, VM, Cluster, L2 Network, Subnet. This widget lists the top 10 talkers in the entity category that you select. It helps the customer to plan for network optimization. The metrics that are represented by bars in this widget are as follows:

- By Flow Volume: Indicates the traffic volume.
- By Traffic Rate: Indicates the rate of traffic.
- By Session Count: Indicates the number of sessions.
- By Flow Count: Indicates the number of flows



**Note:**

- If a VM appears in one or more metrics, when you point to that VM in a bar, it will also be highlighted in other bars.
- When you click a VM in the metrics bar, the complete list of flows coming to this VM is shown.
- When you select VM as the entity in the Top Talkers list, all the flows related to this VM irrespective of it being the source or destination is shown. If you select Source VM in the list, then only the flows coming from this VM are considered.
- If you are considering the physical flows, you can select either Source IP or Destination IP.
- After you select the Source-Destination pair and point on the metric bar, if you click the link in the tool tip, the corresponding dashboard appears. For example, for a VM in Sourec-Destination pair, the VM-VM path dashboard appears.
- For a flow group view or a flow entity projection or a flows group query, you cannot see the **Flow Analytics** button.

## What's New

This section helps you to track what services and entities are discovered in the data center in the selected time range. The widget in this section are as follows:

- New Virtual Machines Accessing Internet: Lists the new VMs that access Internet.
- New Internet Services Accessed: Lists the new Internet services discovered in the environment.
- New Internal Services Accessed: Lists the new intranet services that are discovered and accessed from the Internet endpoint.
- New Internal/E-W Services Accessed: Lists the services that are exposed and accessed by the machines within a data center
- New Services with Blocked Flows: Lists services that have blocked flows. This section is populated only for IPFIX.
- New Firewall Rule Hits: Lists the new firewall rules that are brought into effect. This section is populated only for IPFIX.
- New App-Ids: Lists the new application IDs. This section is populated only for Security Intelligence.

## Network Performance

In this section, you can find and visualize the abnormal flows for the various ranges of TCP Round Trip Time (RTT) values based on the selected criteria.

**Note:**
VCF Operations for networks shows average TCP RTT metrics at 5 minutes granularity for last 24 hours only.

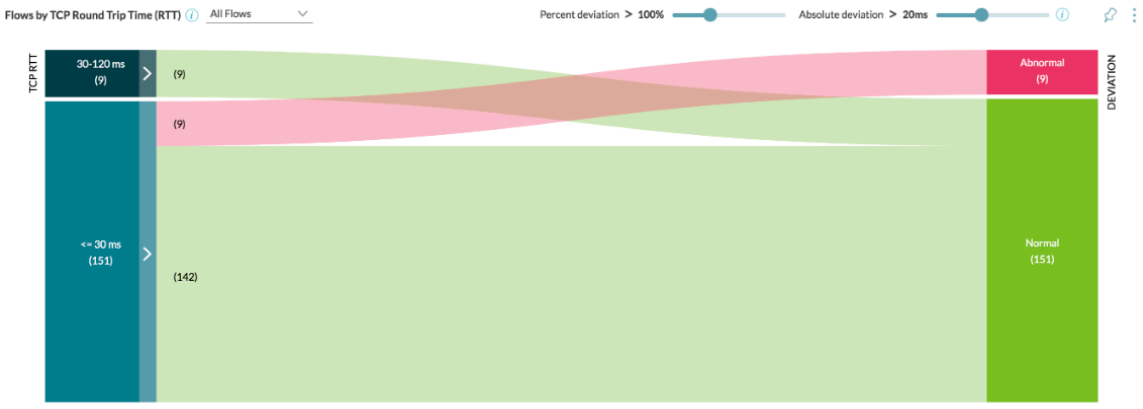
If the flow deviation percentage is 100 percent and absolute deviation is 20 milliseconds (ms), then VCF Operations for networks considers that flow as an abnormal flow.

In the visualization, the left side shows the different range of TCP RTT and the right sides shows the normal and abnormal deviation range. Based on the values of percentage deviation and absolute deviation, flows are connected from left (TCP RTT) to right (DEVIATION). You can analyze the following types of flows:

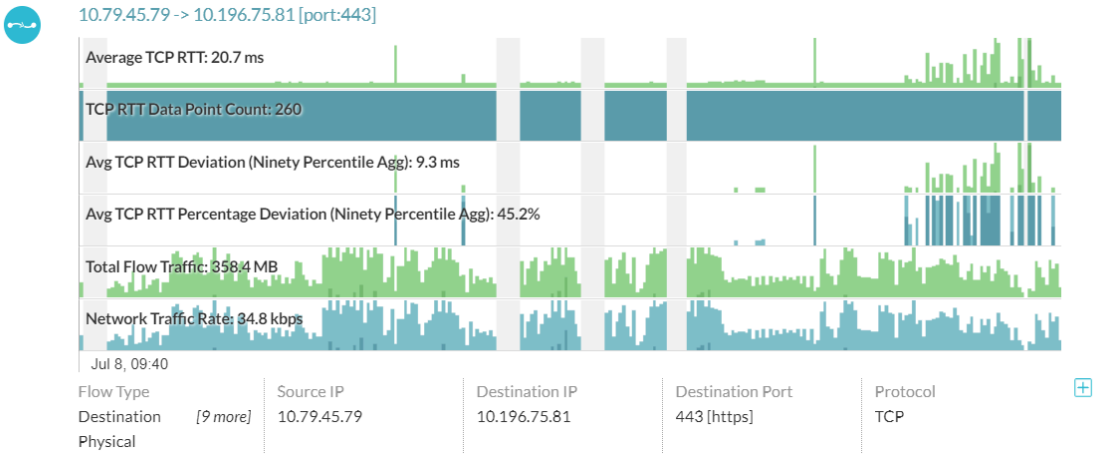
- Inter-Host
- Intra-Host
- Internet
- All Flows

You can also change the percent deviation and absolute deviation based on your requirement.

In the following example, there are two different ranges of TCP RTT, one is less than equal to 30 ms and the other is 30-120 ms. You can find there are total 151 flows comes under the less than equal to 30 ms TCP RTT range. Out of the 151 flows, 9 flows are shown as an abnormal flow.



To get more insight about the TCP RTT distribution information and counts of flows, click the colored line in the visualization. In the following example, you can see the detail insight about the TCP RTT distribution information and counts of flows:

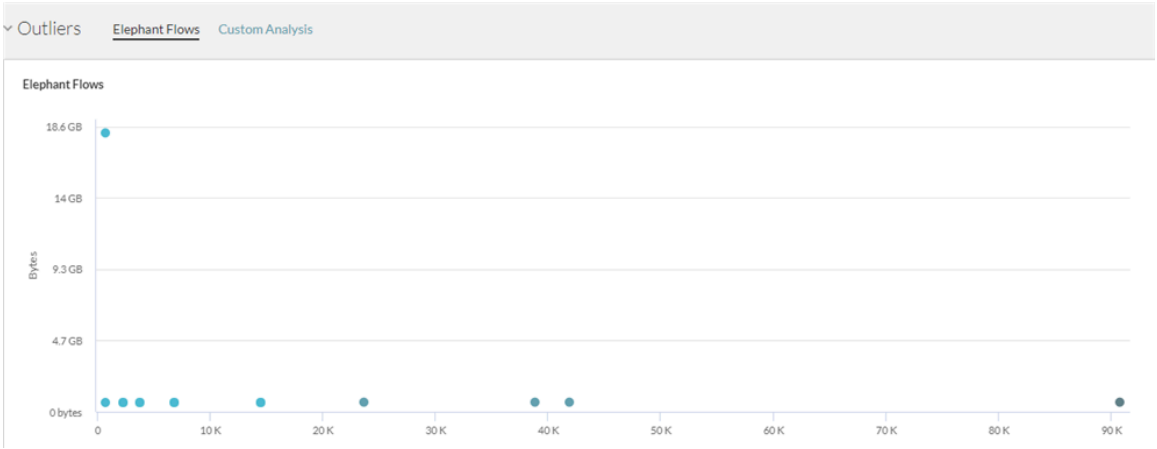


## Outliers

This section helps you to track and analyze related data. It consists of the following sections:

- Elephant Flows: This section helps to identify the flows which have small count of sessions and high throughput versus flows which have large count of sessions and small throughput. Typically, the flows with the large session counts and small throughput are also referred as mice flows. The analysis is based on the ratio of bytes to the number of sessions. Each dot in the graph represents multiple flows. When you point to a dot, you can see the list of flows. To view the details of a particular flow, click that flow in the list.
- Custom Analysis: This section allows you to visualize the flow data on 2 dimensions of your choice. It helps in analyzing the data to find the outliers in various ways.

  **Note:**
  The metrics represented in this section are the approximate values and not the exact values.



## Access Flow Insight page

You can access flow insight from left navigation pane.

1. In the left navigation pane, click **Analytics** > **Flow Insights**.
   You see **Flow Insight** window.
2. From the **Scope** drop-down menu, select one of the following options:

| Option | Action |
|---|---|
| **All flows** | Select to analyze all the flows available in your environment. |
| **Entities** | Select to analyze flows of a particular entity. |

| Option | Action |
|---|---|
| | Click **Entities** and from the drop-down menu select the entity type.<br>You can also use the **Search entity by name** text box to find and select multiple entities.<br>When you click the **Search entity by name** text box, you can see the name of all the available entities for the selected entity type. |
| **Between entities** | Select to analyze flows between two entities.<br>1. From the **Entity type 1** drop-down menu, select an entity type. Also, you can use **Search entity by name** text box to enter the entities names.<br>You can enter multiple entities in the **Search entity by name** text box.<br>2. From the **Entity type 2** drop-down menu, select an entity type. Also, you can use **Search entity by name** text box to enter the entities names.<br>You can enter multiple entities in the **Search entity by name** text box. |
| **Flows matching properties** | Select to analyze flows that match a specific condition. You can add multiple conditions by clicking **ADD CONDITION**. |
| **Custom search** | Select to analyze flows that match a custom search query. |

3. From the **Duration** drop-down menu, select the time frame for which you want to analyze the flows. The system analyzes the flows that occurred between that specific time frame.
4. From the **Ports** drop-down menu, select one of the following:

| Option | Action |
|---|---|
| **All** | Select to analyze all ports available for the selected scope. |
| **Include Ports** | Select to include specific ports that you want to analyze. Enter the names of the ports that you want to analyze in the **Search Ports** text box. |
| **Exclude Ports** | Select to exclude specific ports that you do not want to analyze. Enter the names of the ports that you do not want to analyze in the **Search Ports** text box. |

**Note:**
If you have selected **Flows matching properties** and **Custom search** in **Scope**, you do not see **Ports** drop-down menu.

5. Click **ANALYZE**.

## Analytics - Outlier Detection

VCF Operations for networks offers outlier detection based on the metrics associated with the flows defined over the VMs and physical IP addresses. These VMs/IPs should have similar traffic patterns so that a classification of a particular VM/IP as an outlier is of value. For example, the VMs, which belong to the same tier of an application, generally perform the same function for the application, such as the VMs of an SQL database serving requests for a web application. For these kind of VMs, the number of requests received, the amount of traffic sent out, the session count, and so on go through a series of similar variations.

Through outlier detection, VCF Operations for networks enables you to detect a particular VM which might be experiencing very different traffic pattern compared to other VMs/IPs in the group. For example, if the VM is sending or receiving much higher/lower traffic compared to the rest of the group. It could be because of a wrongly configured load balancer, DDOS attack, and so on. VCF Operations for networks classifies such VMs/IPs as outliers. By looking at these outliers, the user easily knows about this unexpected behaviour and takes appropriate actions.

## How to Detect the Outlier VMs

1. On the sidebar, click **Analytics**. Click **Outlier**.
2. Click **Add** to add a configuration.
3. In the **Analytics/Configure** page, provide the following details for the configuration:

**Table 1335:**

| Field | Description |
|---|---|
| Name | Name of the configuration |
| Scope | Name of the group that defines the VMs and the IPs for which the analysis needs to be done. You can select Application Tier or Security Group as the scope.<br>If you select Application Tier, provide the name of the application and the tier separately. The number of VMs and Physical IPs that are defined for the tier is shown next to the name of the tier.<br>If you select **Security Group**, provide the name of the Security Group.<br>**Note:**<br>The current limit for the number of VMs and Physical IPs in a tier is 200. Choose a tier or a security group with VMs and Physical IPs less than this limit. The scope should also contain a minimum of 3 VMs/Physical IPs.<br>You can view the micro segmentation for the selected configuration by clicking **View Micro-Segments**. |
| Detection Type | Currently, VCF Operations for networks enables you to detect the outlier in the system. |
| Metric | The detection is based on this flow metric. You can select the following options:<br>• **Bytes**<br>• **Packets**<br>• **Sessions**<br>• **Traffic Rate** |
| Traffic Direction | You can select **Outgoing**, **Incoming**, or **Both** as the traffic direction. If you select **Both**, then you can specify Incoming or Outgoing in the preview of the configuration. |
| Traffic Type | You can select **Internet**, **East-West**, or All based on the requirement. |
| Destination Ports | You can either select all ports detected on the flows discovered on the selected scope or manually enter the destination ports of your choice. If you select **All Ports**, the number of the destination ports is shown. If you select **Manually enter ports**, then enter the ports in the autocomplete text box, the analysis would be restricted to only these ports<br>**Note:**<br>The current limit for the number of ports is 20. |
| Sensitivity | It is a measure of the sensitivity of the detection and reporting that you require. The default value is **Medium**. |

| Field | Description |
|---|---|
| Preview | This section provides a preview of the particular configuration based on the inputs and parameters that you have provided. Specify the ports and the traffic direction if you have selected Both for Traffic Direction before. You will be able to identify the outlier VM in the graph. |

**Note:**

- The outlier is detected by evaluating the data available in last 24 hours.
- You need a continuous flow of IPFIX data to detect the outlier.

4. Click **Submit** to create the analytics configuration.
5. Once the application is created, it is available in the list view of the applications in the Analytics Configurations page. Click that particular application to see a dashboard associated with it.

## Analytics: Static and Dynamic Thresholds

You can configure thresholds and receive alerts based on aberrations in the behavior of the entities.

You can configure two types of thresholds:

- Static threshold: If a particular metric value goes beyond or below the configured value, then a static-threshold-based alert is generated.
- Dynamic threshold: If the threshold is determined by the system based on the analysis of the historical data, an alert is generated in case this threshold is violated. The data is analyzed for a period of 7 days before any alert is generated. The process of creating a baseline is restricted to 21 days of the historic data and the older metric values are not considered to create a baseline for the new metric values.

VCF Operations for networks generates an alert immediately after a threshold is violated.

### Configure Thresholds and Alerts

You can add a threshold configuration and gets alerts for the configured threshold.

To configure the analytics-associated thresholds and alerts:

1. On the Home page, in the left navigation pane, click **Analytics** > **Thresholds** > **Add**.
   The **Threshold - Add configuration** page opens.
2. In the **Name** text box, enter a unique name for the configuration.
3. From the **Scope** drop-down menu, select the entities that are to be considered for analysis. For example the entities can be VMs, Flows, etc.
   a) To identify a subset of entities that are to be considered for analysis, enter one or more criteria in the **Select criteria** text box.
4. In the **Condition** section, set a condition to create an alert.
   Based on the condition you set, the system decides if the threshold is violated.
   a) In the **aggregared over** text box, select the grouping of the entity. You can set a threshold on a cumulative metric by aggregating the data over a group of entities.
   b) In the **when** text box, enter the value for which you are checking the threshold.
   c) Configure a static or a dynamic threshold.
      - To configure a static threshold, select either of the following threshold conditions from the list:
        – **exceeds threshold**
        – **drops below**
        – **is outside range**

- To configure the dynamic threshold, select **deviates from the past behavior**. Select the sensitivity based on your requirement of reporting.

d) Enter the upper bound and lower bound range.

When you enter the `Upper Bound` or the `Lower Bound` range, ensure that you enter the value based on the unit of measure for the selected condition. The following conversion values are for your reference:

- `1 Kbps= 1000 bps`
- `1 Mbps= 1000 kbps`
- `1 Gbps = 1000 mbps`
- `1 KB=1024 B`
- `1 MB=1024 KB`
- `1 GB = 1024 MB`

When you set the threshold, you can view the associated graph at the top of the page. The pink bar denotes the VMs or the flows violating the threshold. You can view the list of the entities that have violated the threshold and the entities that are within the threshold in the system.

5. From the **Minimum Violation Duration** drop-down menu, select a time duration after which VCF Operations for networks should trigger alerts if the violation lasts longer than the selected time duration.

   For example, If you set **Minimum Violation Duration** as 15 minutes, you get alerts only if the violations stays active over 15 minutes.

6. Configure the severity of the alert.
7. In the **Notification** section, configure when and who can receive notifications.

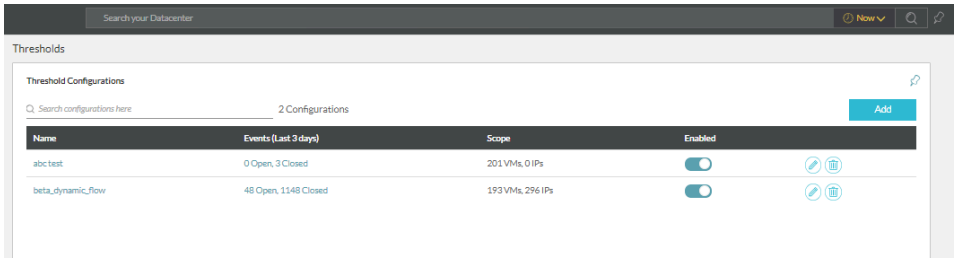
   **Note:**
   Select **Send SNMP Trap** only if you have configured SNMP traps on your system.

8. Click **Submit** to create the threshold configuration.

## View the Threshold Configuration Page

Once you have added a threshold configuration, you can view its details on the **Threshold Configuration** page.

1. On the left navigation pane, click **Analytics**. Click **Thresholds**.

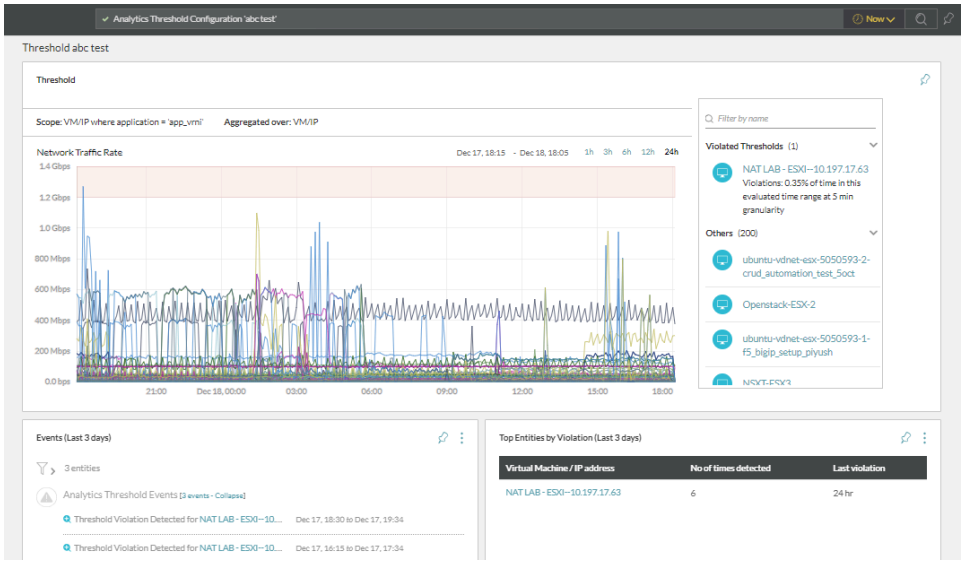


2. The following details for a threshold configuration are provided:

   - `Name`
   - `Alerts`
   - `Scope`

   If the configuration is deactivated, then the alert for the violation of that particular threshold is not generated. You can also search for any particular threshold configuration on this page.

3. Click the desired threshold configuration from the list to view the dashboard for that particular configuration.



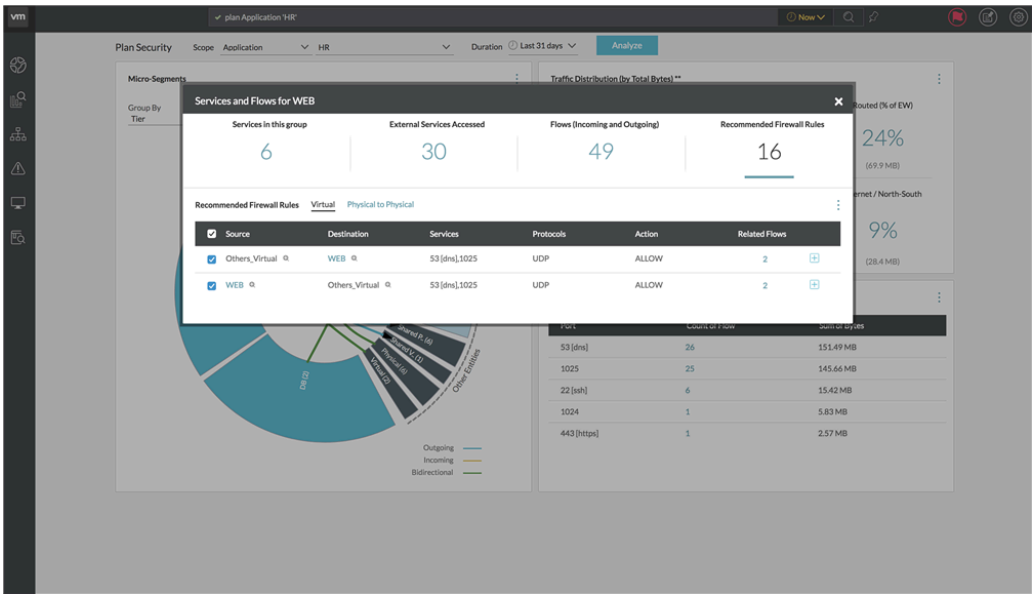
You can view the following widgets on the dashboard:

- Graph: The threshold graph helps you detect the entities that have violated the thresholds.
- Alerts: This widget provides the list of alerts that have been generated for violated thresholds for the last three days.
- Top Entities by Violation: This widget lets you know the top entities that have been the cause of aberrations for the last three days.

## Viewing Recommended Firewall Rules

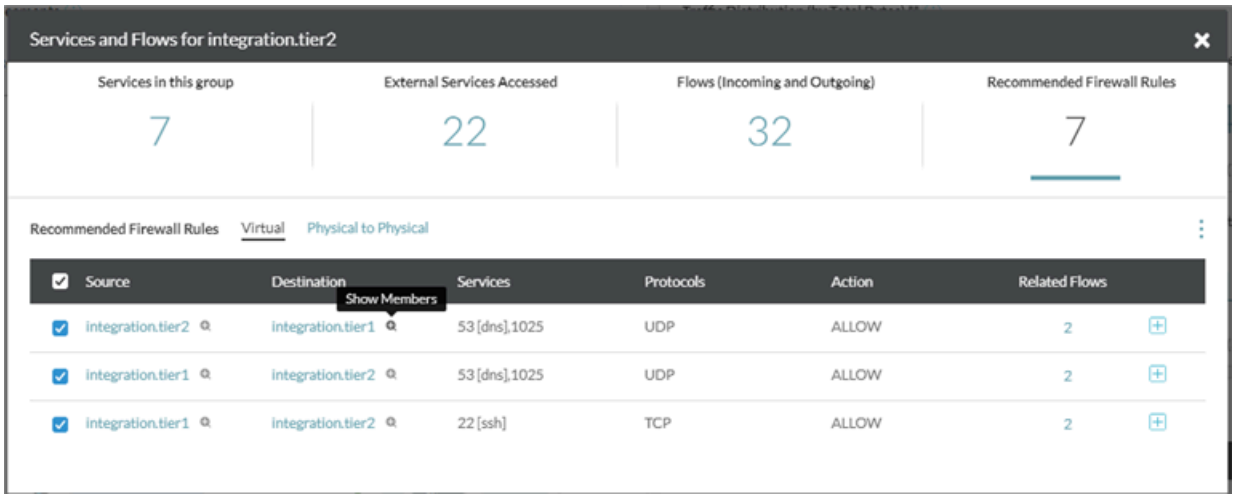
On the **Security Planning** page, when you click the wedge or the edge in the **Micro-Segments** topology diagram, you can view the list of the services, flows, and recommended firewall rules for that particular segment. Click **Recommended Firewall Rules** to view the rules defined on it. The members of the source or the destination are listed under the following types of rules:

- Physical to Physical: This tab lists all the rules associated with the physical and Internet IPs. The rules can be for physical-physical, physical-Internet, Internet-physical, or Internet-Internet entities.
- Virtual: This tab lists all rules where at least one of the endpoints is a VM.



For each firewall rule, the following details are available:

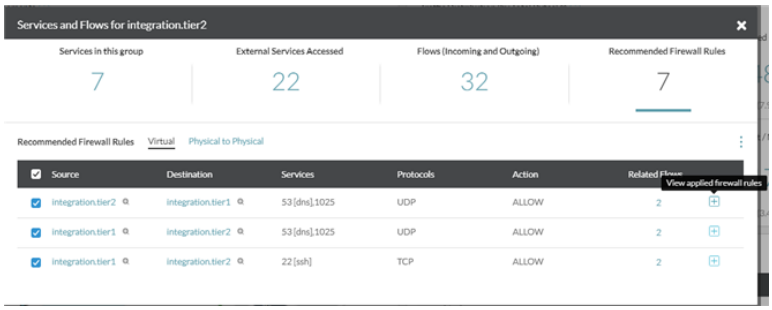
- Show members of the group: Click the + sign next to the name of the entity to see the members of the group.



**Note:**

- The members are not shown for the groups belonging to the Internet category.
- If a security group has both virtual and physical IPs, the physical and the Internet IPs are not shown in the list of the members of that particular group.
- The member Kubernetes services are shown under the **Kubernetes Services** tab.
- If the member count or the entry is zero for **Virtual Machine**, **Physical & Internet IPs**, or **Kubernetes Services** the tab is not visible.

- Source
- Destination
- Services
- Protocols
- Action
- Related Flows: Click the number of the related flows to see the list of flows with the corresponding flow information.
- View Applied Firewall Rules: Click the + sign next to the **Related Flows** column to view the applied firewall rules corresponding to the similar sets of flows.



You can export the recommended rules as XML or CSV based on your requirement.

**Note:**
You can export recommended rules related to Kubernetes objects in the YAML format also.

Refer to Exporting Rules for more information on these artifacts.

## Recommended Firewall Rule to Secure Vulnerable OS

Use the following procedure to get recommended firewall rule to secure vulnerable OS:

1. Go to **Applications** > **All Applications** > **Add**.

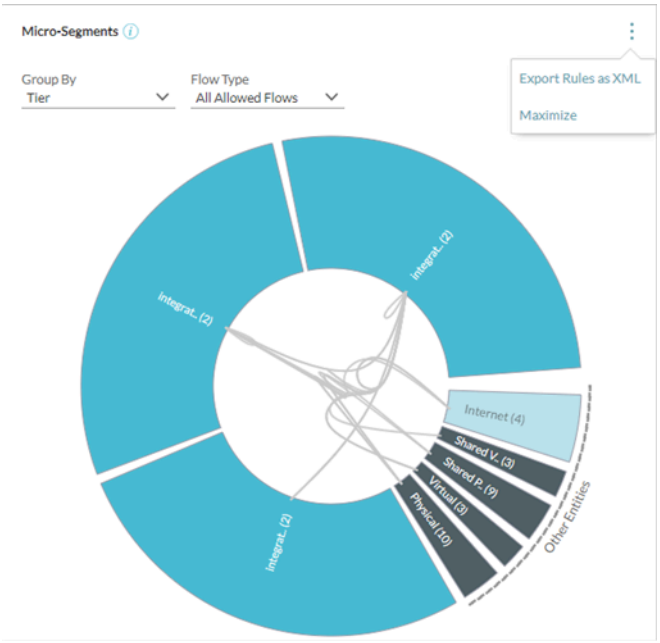
2. In the **Add Application** page, do the following actions:

| Options | Actions |
|---|---|
| **Application Name** | Type a name for the Application |
| **Tier / Deployment** | • Provide a unique name for the tier.<br>• In the **Member** drop-down, select **Custom VM Search** and in the **Search your application environment** text box add the following condition:<br>`in the qualifier put the matching criteria as: Operating System like 'Microsoft Windows Server 2003' or Operating System like 'Microsoft Windows Server 2008' or Operating System like 'Red Hat Enterprise Linux 6' or Operating System like 'Red Hat Enterprise Linux 5' or Operating System like 'SUSE Linux Enterprise 10'` |

3. Click **Save**.
4. Go to **Plan & Assess** > **Security Planning**.
5. In the **Scope** drop-down, select **Application** and the name of application you created.
6. In **Duration** drop-down, select **Last 7 days**.
7. To get the recommended firewall rules, click **Analyze**

## Exporting Rules

You can export all the rules as XML for the entire topology. You can find this menu item in the **Micro-Segmentation Planning** page as follows:



The Export as XML option is available only for the following entities:

- Security Group
- Application Tier

If the planning scope spans a single NSX Manager only, the generated artifacts contain the XML files corresponding to the recommended services and firewall rules. If the planning scope spans multiple NSX managers, the generated artifacts contain the XML files corresponding to the recommended services, IPsets, security groups, and the firewall rules.

The following are the placeholder artifacts for security groups:

- `SG-Others_Internet.xml`
- `SG-Other.xml`

You can export all the rules as XML or CSV for a particular wedge or edge depicted in the topology diagram.

**Note:**
You can export recommended rules related to Kubernetes objects in the YAML format also.

## NSX DFW Universal Artifacts

It is easy to manage objects in universal security groups across the various VMware vCenter and NSX deployments. VCF Operations for networks supports the generation and the import of the universal artifacts for the Application and Tier groups only. With the universal security groups, it becomes easy to deploy and manage the firewall rules easily in the cross VMware vCenter scenarios. Ensure that you import the universal artifacts on the primary NSX manager. You can manage the membership of the universal security group only through the primary NSX manager.

A universal security group can consist of:

- Other universal groups
- Universal IP sets
- Universal Security Tag

When you export the rules as XML, in addition to the NSX manager specific folders, a universal folder is created which consists of the NSX DFW universal artifacts. The corresponding universal security groups, universal IP sets, universal security tags, and universal DFW firewall rules are created after importing the NSX DFW universal artifacts.

**Note:**

- The universal security tag is supported in only active-standby mode.
- The universal IP set is supported in both active-active and active-standby modes.

You can create universal IP set or universal security tag based on your requirement. If you create the universal security tag, then you can map the application VM to the security tag. Else, the universal IP set is used.

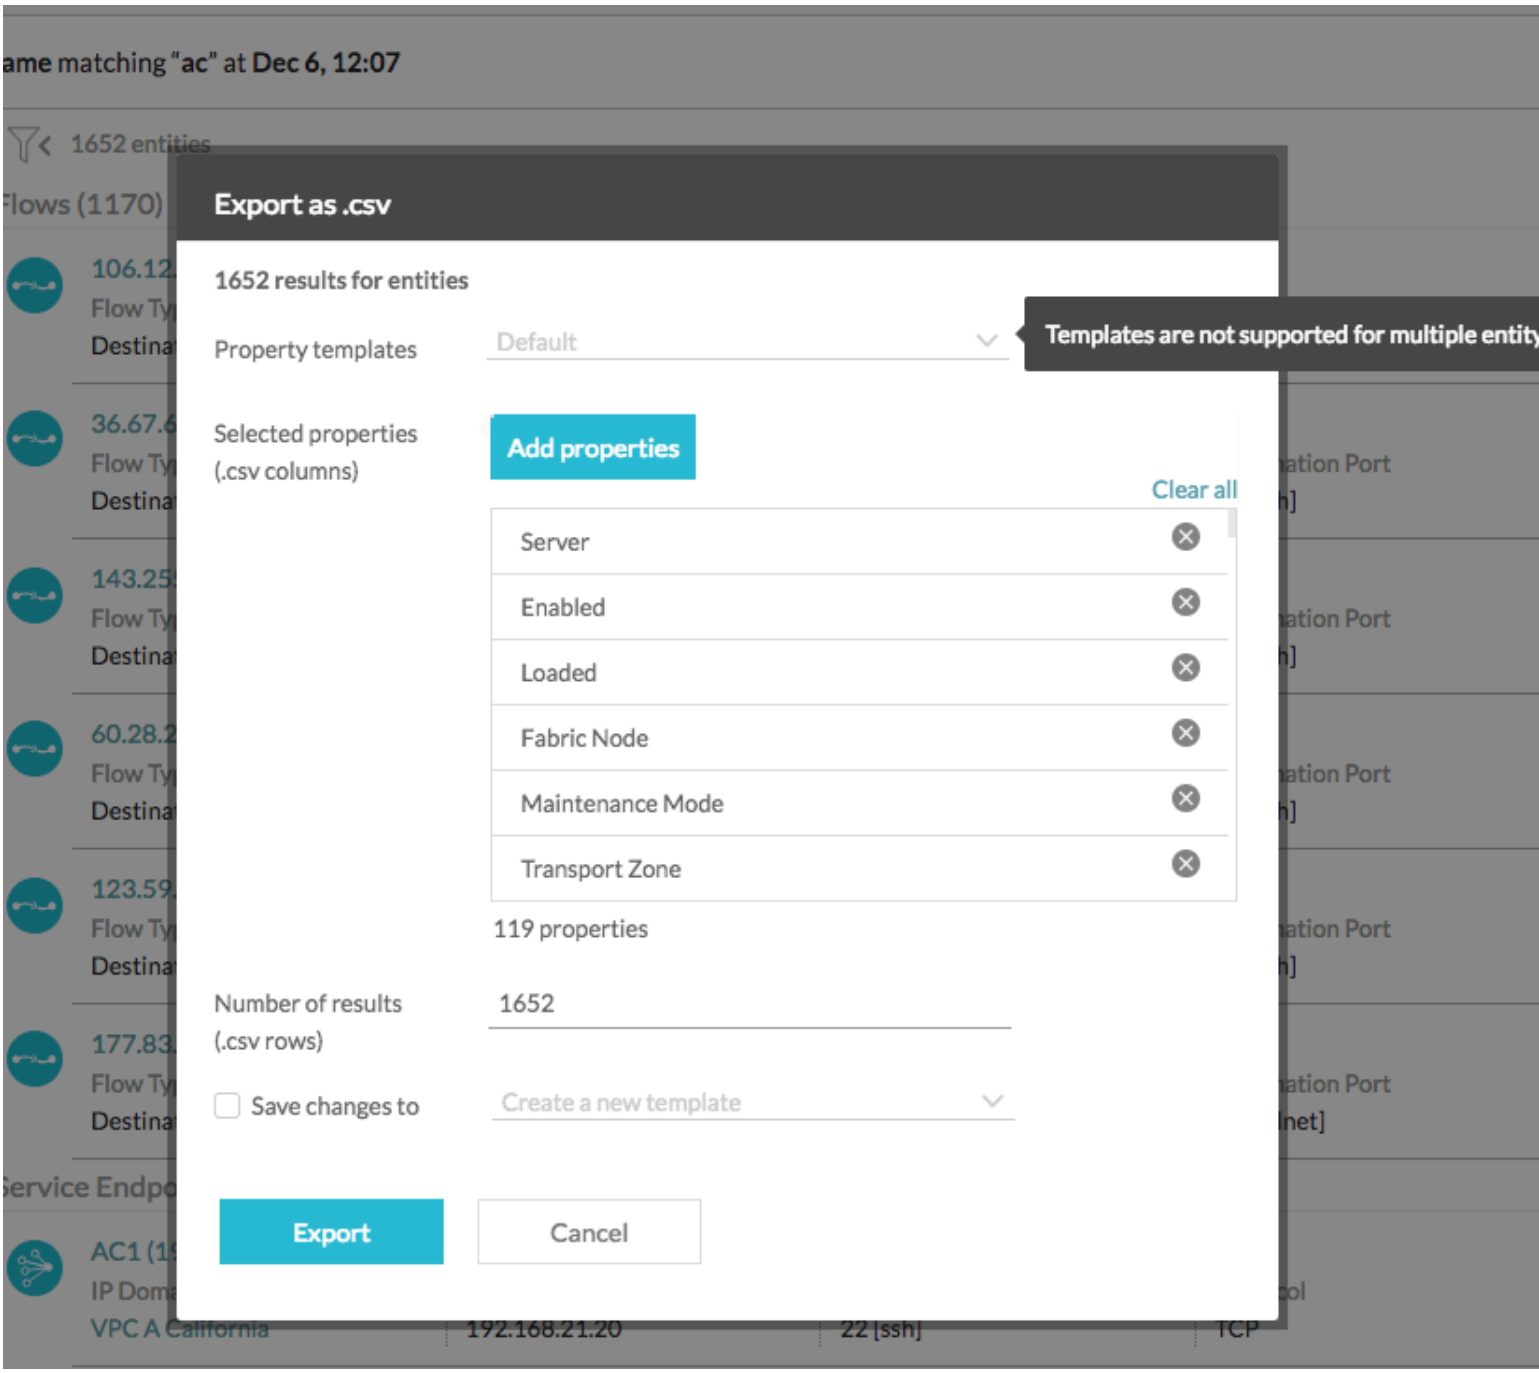
You can use the following flags in the import tool:

| Flag Name | Description |
|---|---|
| `-uni` | To import artifacts from the universal folder. |
| `-utag` | To import the universal artifacts with the universal security tags in the membership of the universal security groups. |
| `-log` | To create rules in which logging is enabled.<br>**Note:**<br>This flag is not specific to universal option. |

## Save the Configuration for CSV Export as Property Template

While exporting the data from widgets in the CSV files, you can save the combination of the properties (or columns) that you want to export in the property templates. These property templates are enabled for the CSV export when the results belong to a single entity type. If you search with a keyword that lists

the multiple entity types, they cannot save the combination of the properties in the property templates.



When you open the CSV export modal, you will see the default property selections for the search results (based on the entity type). You can change this list of the selected properties and save the new configuration for your future reference. Alternatively, you can also load or open a pre-saved property template from the **Templates** section on the CSV export modal. When you change the value, you will see the selected properties for the selected property template.

Once you make changes to the selected properties for the export, you can create a property template from the CSV export modal or edit an existing property template. This template is of the same entity type as that of the current search results.

You can view the list of the existing property templates in the system by navigating to the **Settings -> Property Templates** page. The list on the **Property Templates** page shows the existing templates with details such as entity type, last updated, and number of properties. You can edit or delete property templates from the **Property Templates** page. You can edit the property template except change its name.

## Export and Apply Kubernetes Network Policies

You can export the recommended network policy rules related to Kubernetes objects in the YAML format. VCF Operations for networks supports exporting to YAML format for the group by Namespace and group by Service topologies only.

- Add the Kubernetes cluster as a data source
- Add VMware PKS as a Data Source

1. To export the recommended rules to YAML format, on the Plan Security model, select your Kubernetes cluster for which you wish to plan security, and perform one of the steps.
   - Expand more options in the Micro-Segments widget and select **Export Rules as YAML**, or
   - Select a node on the Micro-Segments wheel view, click on the count of Recommended Firewall Rules, expand more options and select **Export Rules as YAML**.

   VCF Operations for networks downloads a ZIP file named with the Kubernetes Network Policies and a timestamp associated with it. When you unzip the file, you see the following five CSV files and also multiple folders depending on the number of clusters. Each folder will contain multiple YAML files for the cluster.

| File Name | Description |
|---|---|
| `network-policy-others-ipaddress.csv` | Contains the IP addresses of the physical servers and virtual machine with which the services or namespaces are communicating. |
| `recommended-namespace-labels-to-add.csv` | Contains the labels to be attached to the pods associated with the namespace.<br>Example:<br>• **Cluster** - pdk8s<br>• **Namespace** - sock-shop<br>• **Label** - sock-shop-pdk8s |
| `recommended-service-labels-to-add.csv` | Contains the labels to be attached to the pods associated with the service.<br>Example:<br>• **Cluster** - pdk8s<br>• **Namespace** - sock-shop<br>• **Service** - front-end<br>• **Label** - Service:front-sock-shop-pdk8s<br>• **Cluster** - pdk8s<br>• **Namespace** - sock-shop<br>• **Service** - user<br>• **Label** - Service:user-sock-shop |
| `recommended-network-policy.csv` | Contains all the rules recommended by VCF Operations for networks. |
| `exported-network-policy-rule-names.csv` | Lists all the network policies exported based on the recommended rules. |

2. To apply the service labels, perform the following steps:
   a) Run the following Kubernetes CLI command.

   `kubectl edit deployment` *`service-name`* `-n` *`namespace-name`*

   `kubectl edit deployment` *`redis-primary`* `-n` *`guestbook`*

   The deployment file of the service opens.

b) In the service label list, append the label which has been suggested in the CSV file, to the labels mentioned in the spec section of service deployment.

3. To apply the namespace labels, perform the following steps:
   a) Run the following Kubernetes CLI command.
      `kubectl edit namespace namespace-name`
      `kubectl edit namespace guestbook`
      The deployment file of the namespace opens.
   b) In the metadata , append the label which has been suggested in the CSV file, to the labels mentioned in the `spec` section of namespace deployment.
4. Run the following command to verify whether the labels are applied to the pods.
   `kubectl get pods -n namespace-name--show-labels`
   `kubectl get pods guestbook--show-labels`
   See the labels in the result view.

   **Note:**
   The labels are not reflected on Pods, when you apply on Namespace.
5. To create the network policies, copy the YAML files from the respective cluster folder to another folder and run either of the commands:
   - `kubectl apply -f <folder-name>/` - to apply all the firewall rules together.
   - `kubectl apply -f <folder-name>/<firewall-rule>.yaml` - to apply firewall rules one by one

## Working with Search Queries

VCF Operations for networks provides a robust search for all the entities in your environment.

VCF Operations for networks provides a list of pre-defined list of search queries out-of-the-box under **Help** > **Useful Searches**. You can refer or use these queries as a syntax to structure the search query, and modify them as per your requirement. Each of these queries are associated with a description and a set of tags. You can also filter these search queries based on a keyword or a specific tag. When searching for a query, you get alternate search suggestions if the search fails to show results for that query.

To run the query, you can click on a query in the list. When you select a query that does not require a parameter value, the query would be executed directly. If a query requires a parameter value, the homepage of VCF Operations for networks opens in a new tab which shows the query with the sample value. You can replace them with the actual values like host name, application name, that exists in your setup.

The **Supported Properties** option on the **Help** page displays the list of entities, which when expanded displays all the supported properties, description, sample queries and tags of the particular entity. You can filter the properties based on the tags.

You can use the **View Search Query** option on the widget to see the search queries that are associated with each widget on the pinboards. Also, VCF Operations for networks enables you to copy the query, which you can modify and execute on the search bar. If multiple sub-widgets exists in a widget (for example, an Overview widget on a dashboard), you can see the queries for each sub-widget that are associated with the respective name.

**Note:**
As of now, the **View Search Query** option is available for the only following:

- NSX Manager Details
- Flow Insights Details
- Application Details
- Home Page
- VM Details
- Host Details
- NSX-T Manager topology
- NSX-T Host Transport Node

- NSX-T Edge Transport Node
- NSX Policy Manager Details

Here are some of the terms that can help you with the search feature in VCF Operations for networks:

- Entities: A data center consists of physical and logical building blocks such as host, virtual machine, switch, router, NSX Manager and so on. The instances of these blocks are entities.
- Property: An entity consists of multiple properties. A property can be either a configuration property or a metric property.
  a. Configuration Property: An entity can be described by its configuration properties. A configuration property can be either integer or real value or a string or a boolean value.
     - Name, CPU cores, and operating system for virtual machines
     - Name, and number of virtual machines for hosts
  b. Metric Property: Any property which measures a particular characteristic of an entity is a metric property. The values of metric properties are captured at regular intervals of time. CPU usage, memory usage, and network usage for virtual machines are some examples of metric properties.
- Aggregate Functions: They can be used in the search queries to compute the total number of instances of a particular entity type or maximum property of an entity. VCF Operations for networks supports following aggregation functions.
  a. `sum`
  b. `max`
  c. `min`
  d. `avg`

When you search for entities, the software displays the entities that match your search query on the **Results** page.

For each search query, the search bar suggests you the next term that you can use to narrow down your search results. For example, when you enter the term **vm**, the search bar displays a possible list of terms that you can add to your existing term to narrow down your search results. The search bar also validates each search query. A check mark denotes a valid search query and a cross mark denotes an invalid search query.

## Save and Delete Search Queries

VCF Operations for networks allows you to run a search query and save the query for later use. It also allows you to delete the saved searches.

**Note:**

- VCF Operations for networks provides the following default saved searches:
  – All Flows
  – Applications
  – Azure
  – Kubernetes Dashboard
  – Top Trends
  – NSX
- You cannot save or delete the default saved searches.
- You cannot save an invalid search query.
- The saved searches are user specific and the default saved searches are available to all the users.

1. To save a query, run a search and click the bookmark icon next to the search bar.

   You see the bookmark icon highlighted to ensure that the the query is saved. You can find the search listed under **Saved Searches** in the left navigation pane. To see all the queries that are saved, click **Saved Searches** > **Manage saved searches**.

2. To delete the saved search, click on the bookmark icon again and click **Delete** on the confirm action dialog box.

   You can also delete the saved search from the **Manage saved searches** window.

3. To delete multiple saved search queries together,
   a) In the left navigation pane, click **Saved Searches** > **Manage saved searches**.
   b) Select the queries that you want to delete.
   c) Click the **Delete** option.
   d) Confirm the delete.

## Search Queries

The search queries runs searches across your entire deployment and enables you to find all types of entities based on the specified search term. Additionally, VCF Operations for networks provides suggestions to build the queries, which includes saved searches and recent searches that match the typed text in the global search bar.

Search queries can be divided into following categories:

1. **Structured Queries**
   A structured query consists of the following components:

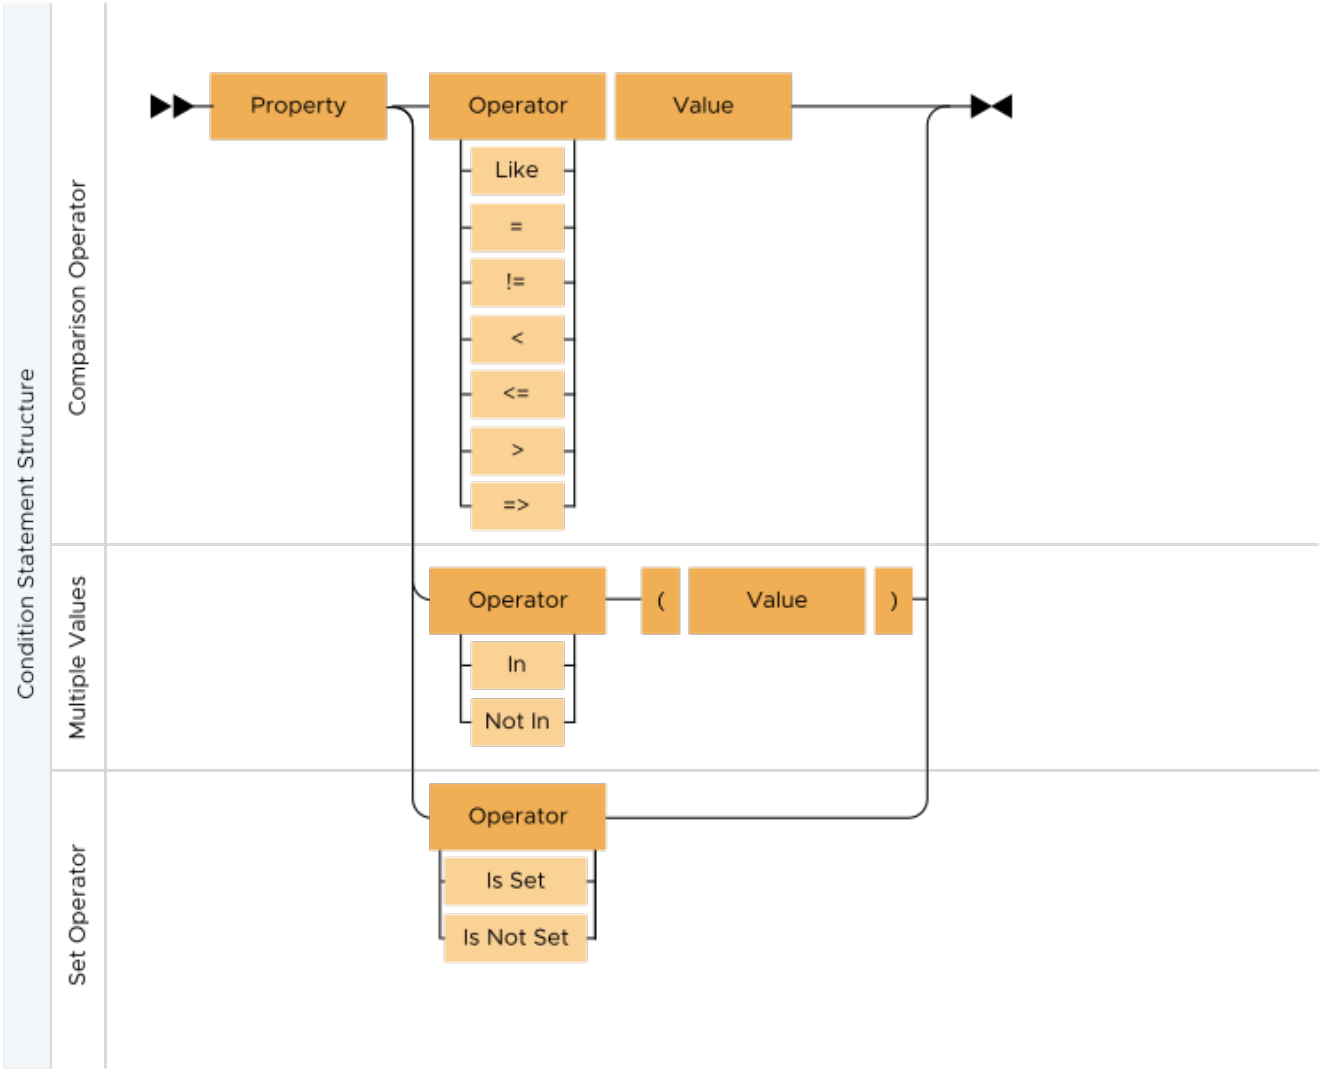
   – **Entity Type**: An entity type represents the type of object that we want to search. And it can be either in a singular form or in a plural form. The entity type is mandatory in a structured query.

   Here are some examples:
   a. `Virtual machines`
   b. `Hosts`

c. `Flows`
d. `MTU Mismatch Alerts`
e. `Problems`

– **Filters**: The syntax for filter is as follows:

The syntax for condition is as follows:



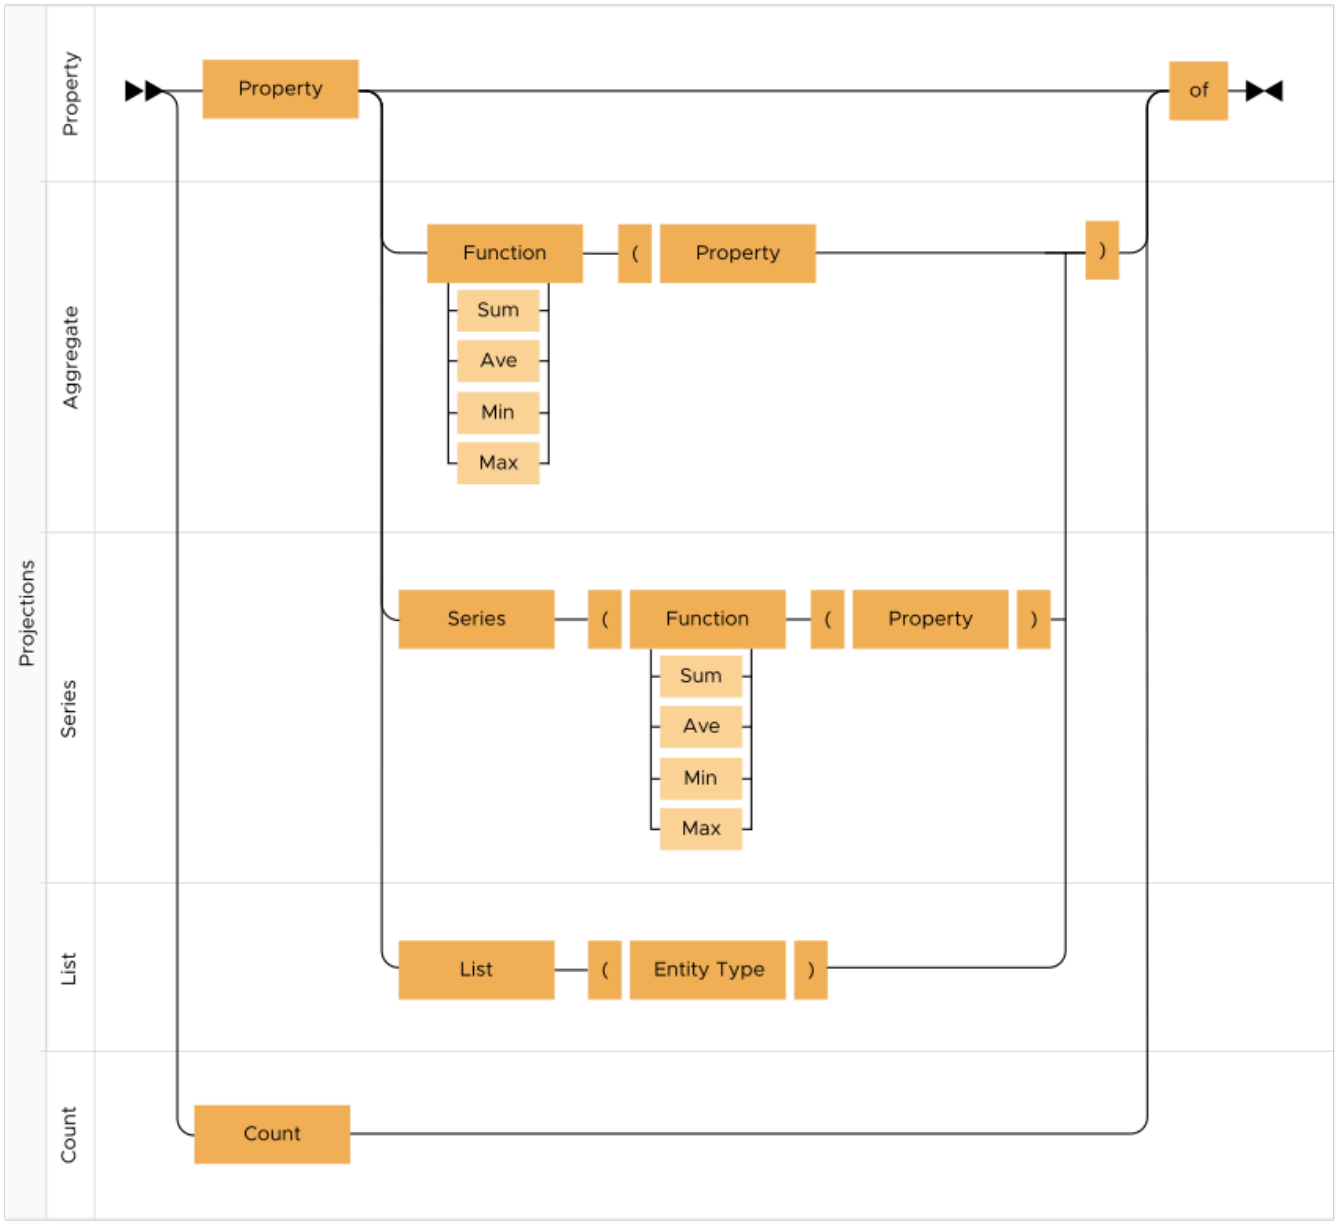
A filter clause can be used to filter search results. The condition in a filter clause consists of property, comparison operator, and value. The conditions can be combined with logical operators to form complex conditions. Here is a list of the operators that you can use:

| Operator | Examples |
|---|---|
| = | `flows where source ip address = '10.16.240.0/24'`<br>`flows where flow type = 'Source is VM'` |
| != | `vms where ip address != '10.17.0.0/16'` |

| Operator | Examples |
|---|---|
| > | `vms where memory > 4096 mb` |
| < | `vms where cpu usage rate < 70%` |
| >= | `vms where memory >= 4096 mb` |
| <= | `vms where cpu usage rate <= 70%` |
| like | `vms where name like 'app'` |
| not like | `vms where name not like 'app'` |
| in | `flows where port in (22, 23, 80, 443)`<br>`vm where ip address in (192.168.91.11, 192.168.91.10)` |
| not in | `flows where port not in (22, 23, 80, 443)`<br>`vm where ip address not in (192.168.91.11, 192.168.91.10)` |
| is set | `vms where firewall rule is set` |
| is not set | `vms where firewall rule is not set` |
| () | `flows where (src tier = 'App' and destination tier = 'DB') OR (destination tier = 'App' and source tier = 'DB')` |
| and | `flows where src tier = 'App' and destinationtier = 'DB'` |
| or | `flows where flow type = 'Source is VMKNIC' or flow type = 'Destination is VMKNIC'` |
| matches | `vm where name matches '.*'`<br>`vm where name matches 'a.*'`<br>`vm where name matches '[a-z]vm-delta[0-9]'` |
| not matches | `vm where name not matches '.*'`<br>`vm where name not matches 'a.*'`<br>`vm where name not matches '[a-z]vm-delta[0-9]'` |
| nested 'in' operator | `vm where in (vm where name = 'x')`<br>`vm where in (vm of host where name = 'x')`<br>`vm where host in (host of vm where name = 'x')`<br>`vm where name in (name of vm where name = 'x')` |

**Projections**: A projection clause in a query decides what fields must be displayed from the filtered entities. This is an optional clause. If the projection clause is not specified, then the default set of fields is shown in the search results. A projection clause can contain any one of the following items:

1. Property
2. Count
3. List
4. Aggregation
5. Series



a. **Property**: When entities are searched by an entity type, default set of properties are shown in the search results. Using projections, we can select the fields that should appear in the search results. For example, `os of vms` lists all virtual machines with `OS property` in the search results.
   Here are some more examples:

   - `cpu cores of vms`
   - `source ip address of flows`

   If a metric property is used, a graph is displayed for each entity with the metric property as `y-axis` and time as `x-axis`.
b. **Count**: The count query can be used to compute the number of objects of an entity type. Here are some examples:
   - `count of vms`
   - `count of hosts`
   - `count of flows`
c. **List**: A list operator is helpful if the filter condition cannot be applied on the entity that you fetch.
   For example:

`List(host) of vms where memory <= 2gb`

This query fetches list of hosts, whereas the filter condition is applied on virtual machines. For example,

`List(ip address)of vms where cpu cores = 1`

**Aggregate functions**: An aggregate function allows you to calculate a single value from a numerical `config` or `metric` property. The search query language supports the following aggregate functions:

- `max`
- `sum`
- `min`
- `avg`

Here are some examples:

- `sum(memory) of hosts`
- `sum(memory), sum(cpu cores) of vms`
- `sum(bytes) of flows`

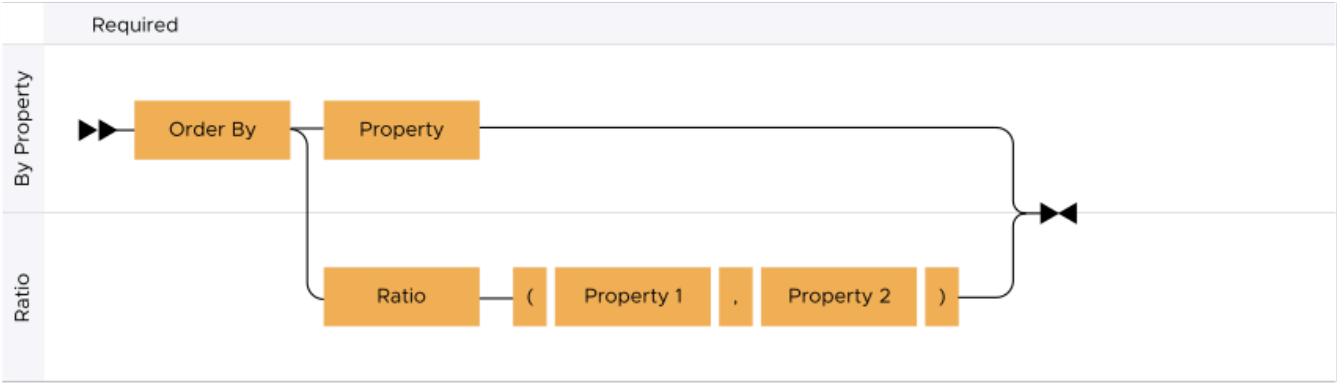
d. **Series**: A series operator is used to perform aggregation on the metric properties. For example:

`series(avg(cpu usage)) of vms where cpu cores = 4`

This query displays graph containing average cpu usage of all virtual machines with 4 cpu cores. Here are some examples:

- `series(sum(network usage)) of vms where name like 'app'`
- `series(sum(memory usage)) of vms where name like 'db'`
- `series(avg(cpu usage)), series(avg(memory usage)) of vms`

– **Ordering**: The search results can be sorted using `order by` clause. Only one field is allowed in `order by` clause. Results are sorted in descending order by default.



Here are some examples:

a. `vms order by cpu cores`

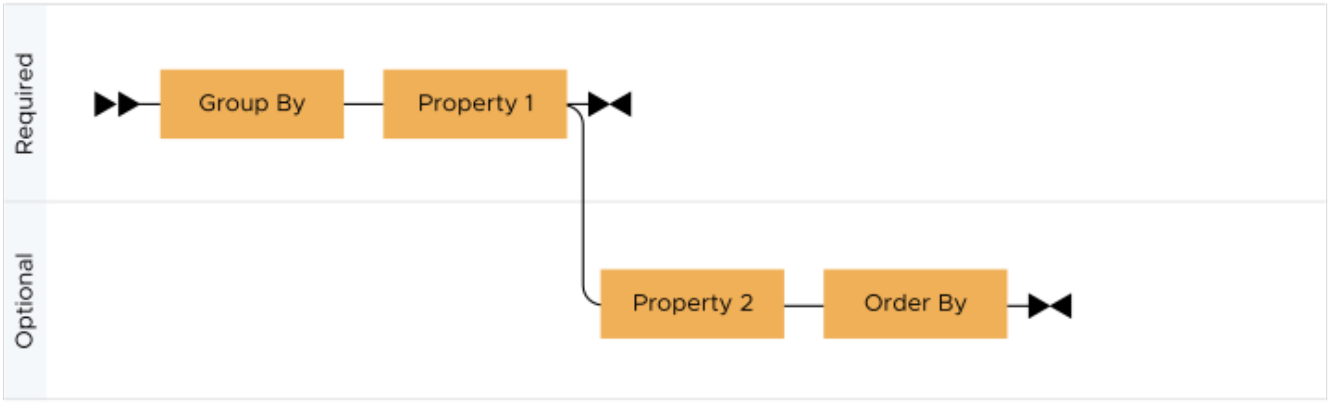
b. `vms order by cpu cores asc`

c. `flows order by bytes`

The `limit` clause can be used to limit the number of results. This must be preceded by the `order by` clause. For example:

`vms order by memory limit 5`

– **Grouping**: The entities can be grouped by a property. When entities are grouped by a property, by default, the number of results in each group are shown. By adding a projection, sum/max/min of any property can be computed . Adding `order by` clause sorts the results. If `order by` or `projection` clause is present in a query, then the aggregation function must be present.



`sum(bytes) of flows group by dest vm`

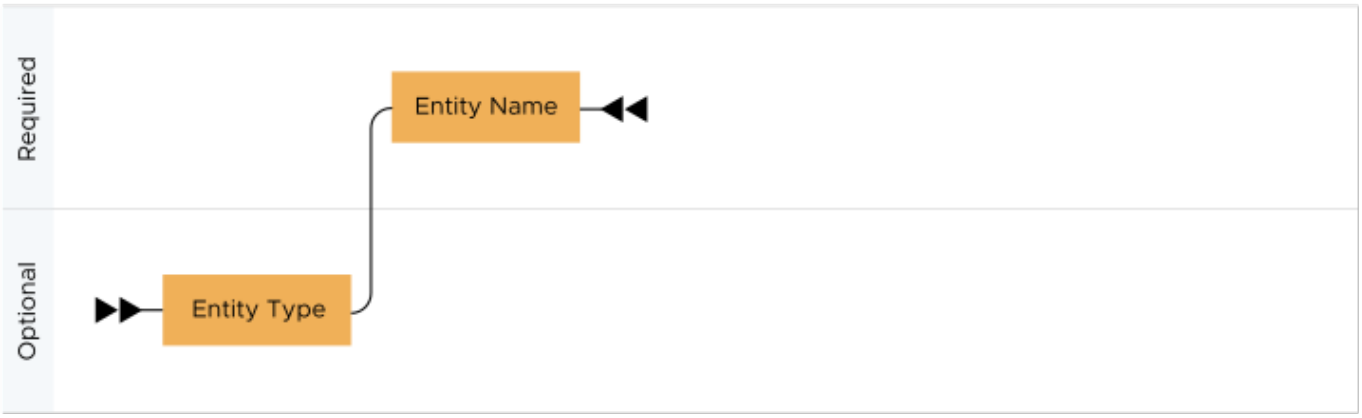
This query is valid as the query has aggregation function in the projection clause. A query such as `bytes of flows group by dest vm` is invalid as there is no aggregation function in the projection clause.

Here are some examples:

a. `vms group by host`

b. `sum (bytes) of flows group by dest vm order by sum(bytes)`

2. **Entity Queries**



**Search by entity type**: All entities of an entity type can be listed by searching the entity type.

Examples: `vms` , `hosts`, `flows`, `nsx managers`

a. **Search by entity name**

- Search by full name: If the full name of an entity is known, it can be searched by enclosing the name in single quotes.

  Examples: `'prod-68-1'`, `'app1-72-1'`

- Search by partial name: Search by a single word or multiple words fetches all the entities matching the input words.

  Examples: `prod`, `app1`

**Note:**

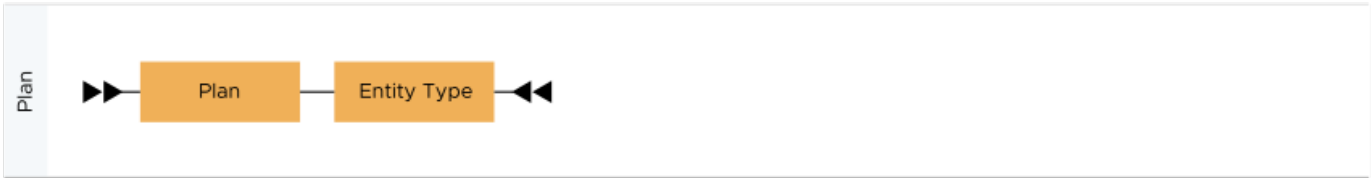
If input contains keywords or entity types, then it may be processed as a search query.

- Search by entity type and name: If both the name and the type of an entity are known, it can be searched by querying entity type and entity name together.

  Example: The search query `'vm app1'` returns all VMs containing `app1`.

3. **Planning Queries**

These queries can be used to plan the security of the data center by analyzing flows.

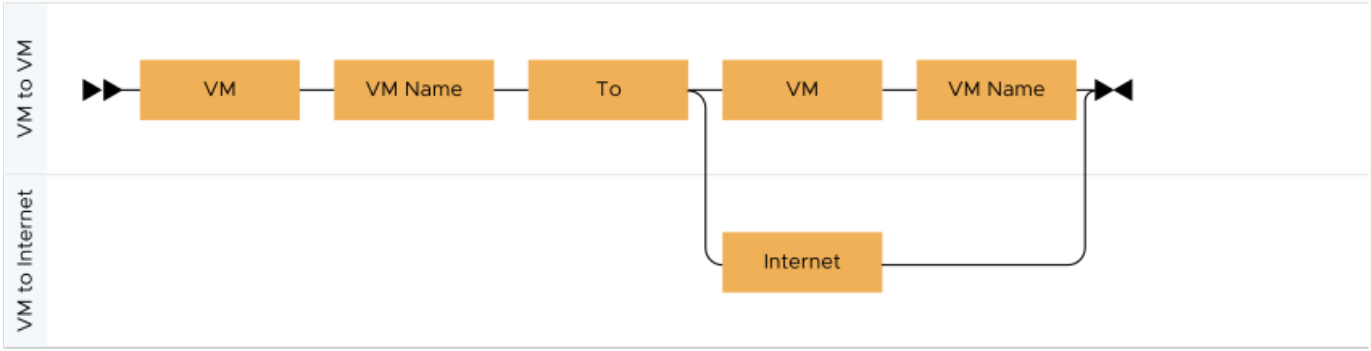


Examples:

1. `plan securitygroup1`
2. `plan host1`
3. `plan security`

4. **Path Queries**

These queries can be used to show the path between two VMs or the path from VM to Internet.



Examples:

1. `Vm 'vm1' to Vm 'vm2'`
2. `VM 'vm1' to Internet`

**Note:**

- The search queries are not case-sensitive.
- The entity types or the configuration properties can have synonyms. For example, entity type `'virtual machine'` has synonym `'vm'`.

## Azure Search Queries

You can search Azure entity details in VCF Operations for networks.

Here are some sample search queries:

| Azure Entities | Sample Queries |
|---|---|
| Microsoft Azure | `Azure` |
| Azure Application Security Group | `Azure Application Security Group where Azure Virtual Network = 'Test-vnet2'` |
| Azure Data Source | `Azure Data Source` |
| Azure NSG Rule | `Azure NSG Rule where Action = 'ALLOW'` |
| Azure Network Interface | `Azure Network Interface where Azure Virtual Network = 'Test-vnet2'` |
| Azure Network Security Group | `Azure Network Security Group where Subscription = 'vRNI-dev'` |
| Azure Route | `Azure Route where Route Table = 'TestRouteTable'` |

| Azure Entities | Sample Queries |
|---|---|
| Azure Route Table | `Azure Route Table where Azure Virtual Network = 'aks-vnet-28255566'` |
| Azure Subnet | `Azure Subnet where Azure Virtual Network = 'vrni-01-vnet'` |
| Azure Subscription | `Azure Subscription` |
| Azure Virtual Machine | `Azure Virtual Machine where Azure Application Security Group = 'TestASG'` |
| Azure Virtual Network | `Azure Virtual Network where Azure Peer Virtual Network = 'vrni-01-vnet'` |

## Search Queries for Cisco ACI Entities

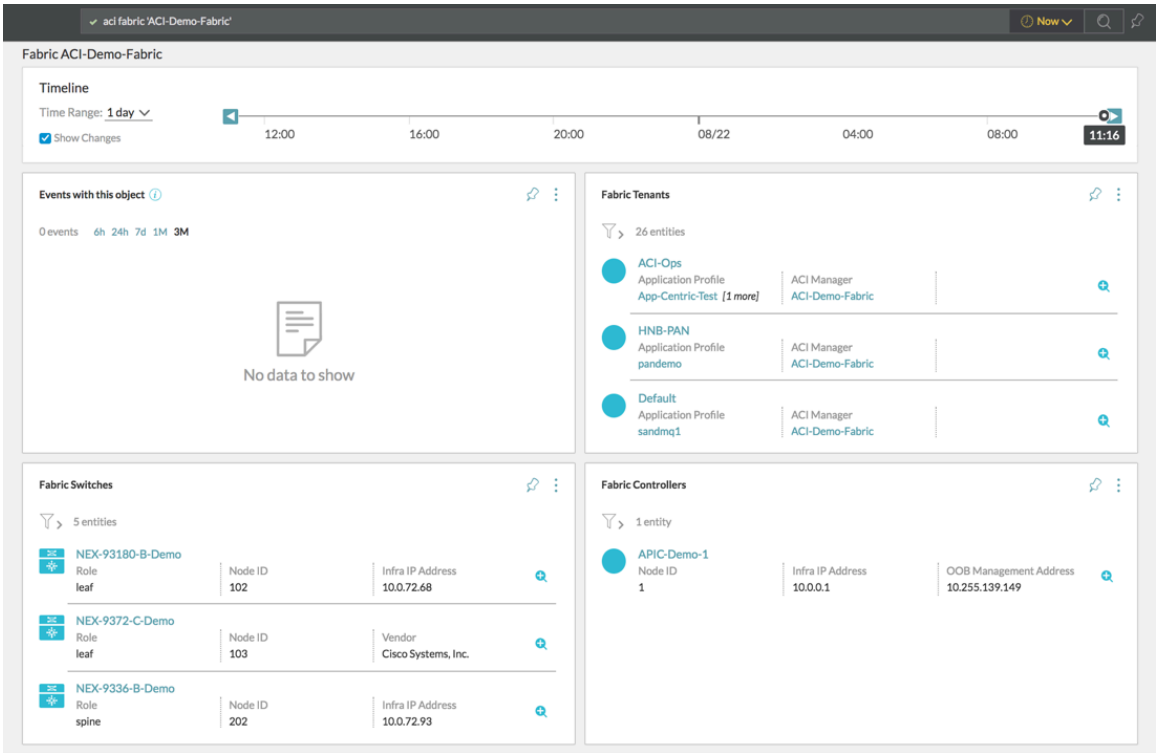
Here is a list of some of the Cisco ACI entities on which you can perform a search:

**Note:**
The entities are prefixed by `aci`.

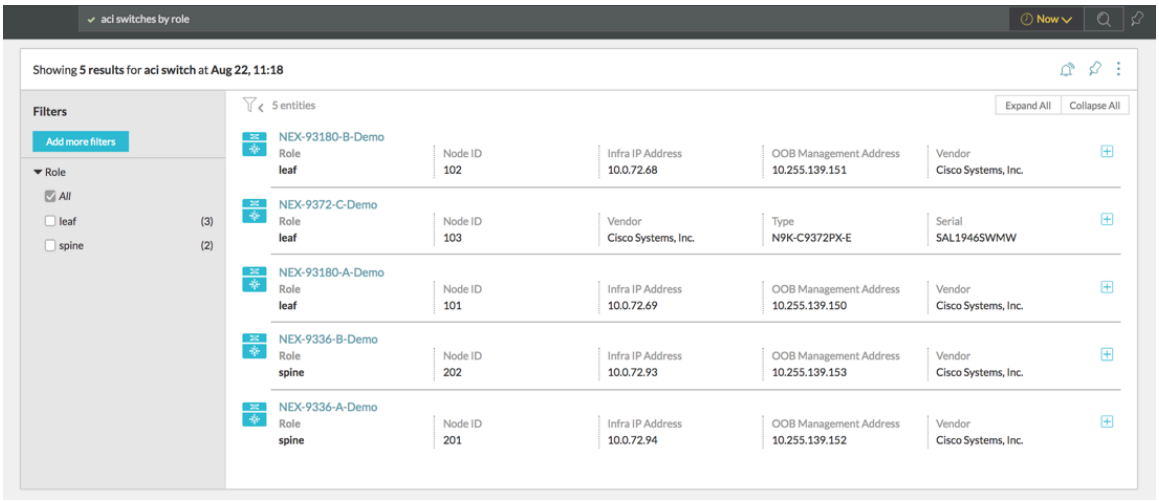
- `aci application profile`
- `aci bridge domain`
- `aci contract`
- `aci endpoint group`
- `aci fabric`
- `aci switch`
- `aci tenant`
- `aci zoning filter`
- `aci zoning rule`

Here are some sample search queries:

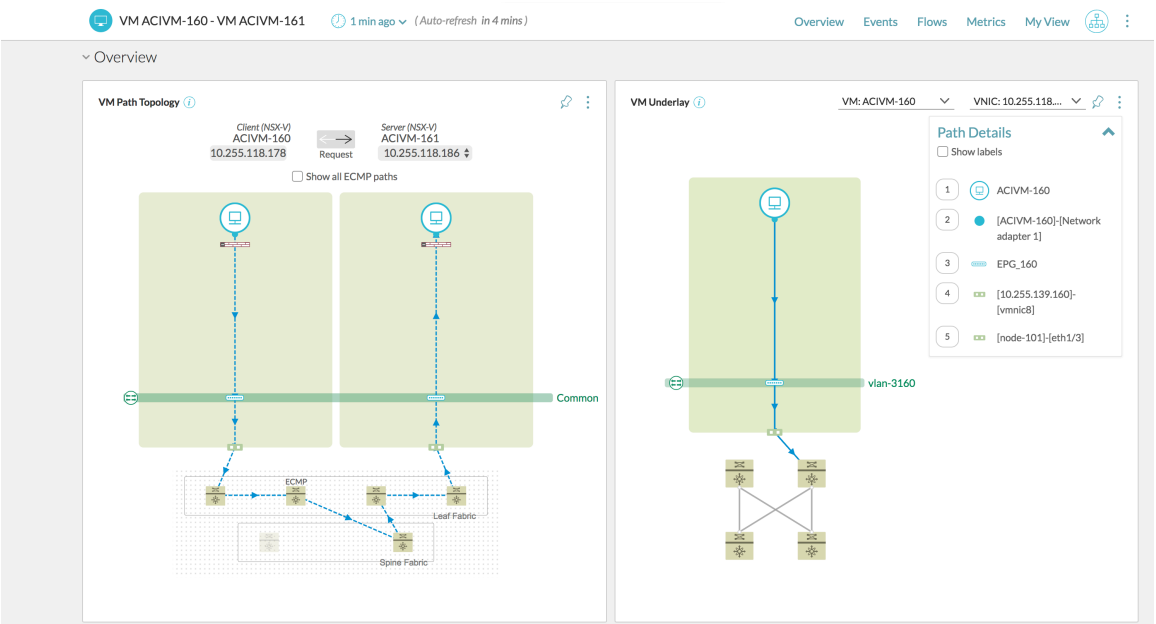
- `aci fabric 'ACI-Demo-Fabric'`: This query retrieves information on the tenants, switches, and controllers in the ACI fabric.



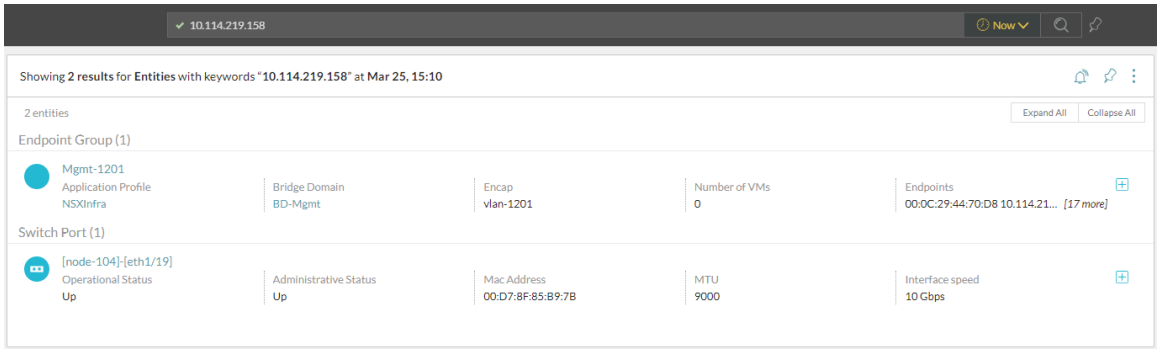
- `aci switches by role`: This query retrieves information on the various leaf switches or the spine switches in the ACI fabric.
  From the switch list, click a switch name to get more details about it.



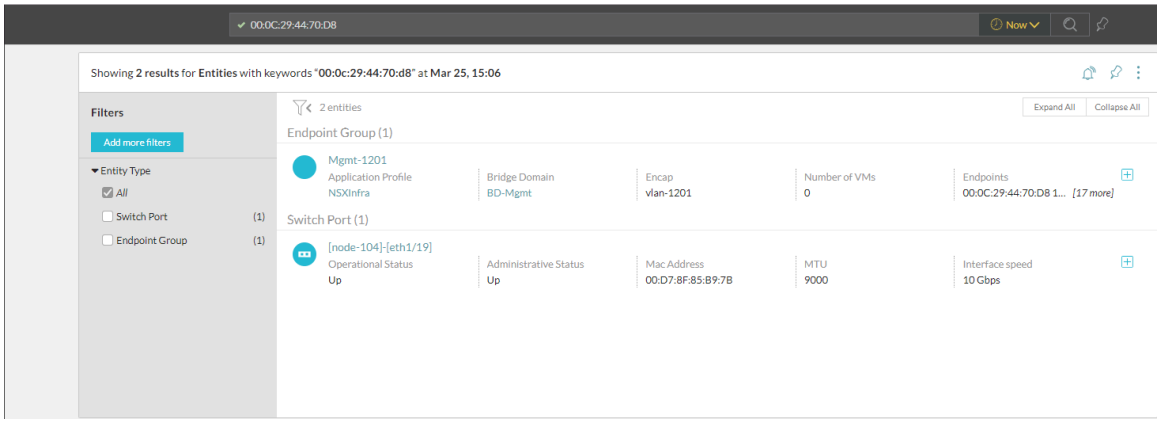
- `aci endpoint group`: This query retrieves a list of the endpoint groups with the associated VMs, bridge domains, and VRFs.
- `aci application profile 'Production'`: This query retrieves the application profile of Production with the contained endpoint groups and VMs.
- `VMware VM 'ACIVM-160' to VMware VM 'ACIVM-161'` : This query shows the VM-VM path between the two VMs.



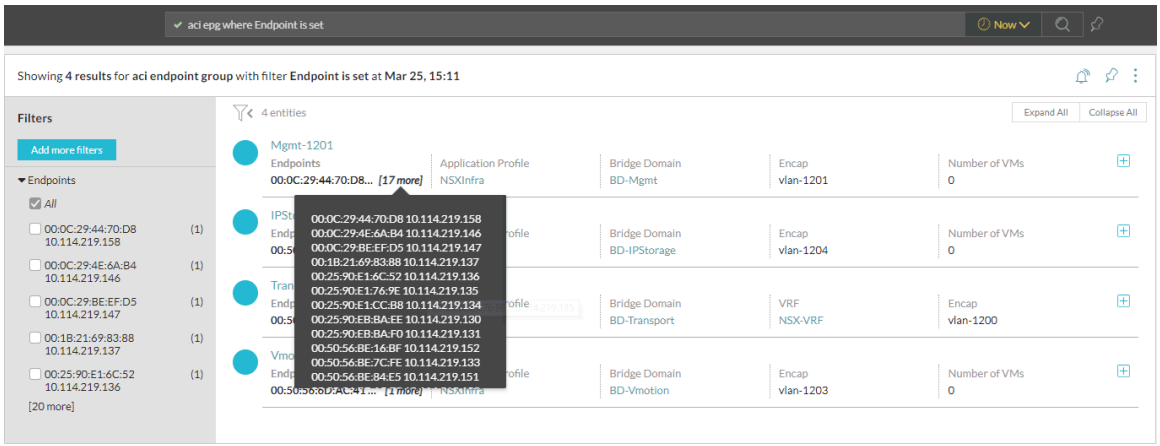
- You can search with IP address to get the port, end point group, and bridge domain details.



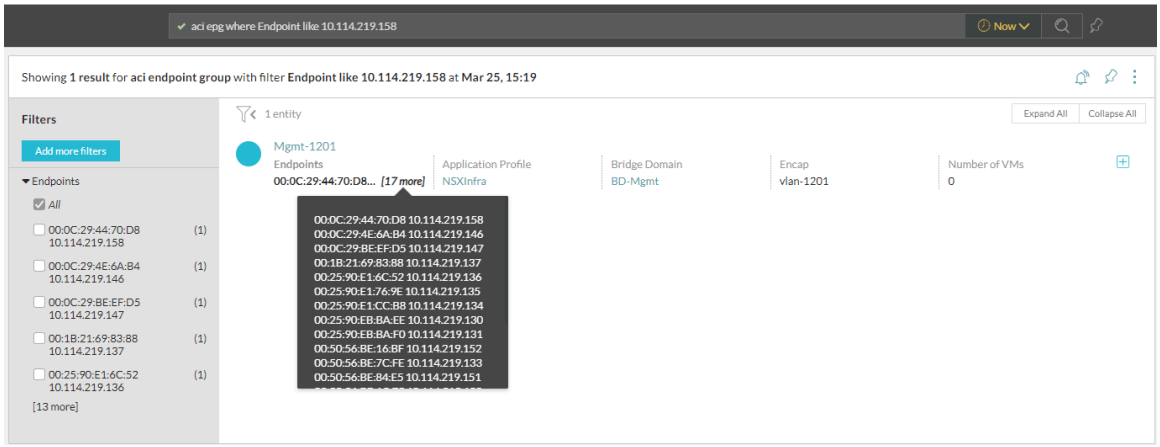
- You can search with Mac address to get the port, end point group, and bridge domain details.



- You can search for an end point group and get the list of associated endpoints.



- You can search for an endpoint.



## Palo Alto Search Queries

You can search Palo Alto entity details in VCF Operations for networks.

Here are some sample search queries:

| Entities | Queries |
|---|---|
| Palo Alto Address | `Palo Alto address where vm = <>`<br>`VM where Address = <>` |
| Palo Alto Address Group | `Palo Alto address group where Translated VMs = <>`<br>`VM where address group = <>` |
| Palo Alto Device | `Palo Alto Device where Version = <>`<br>`Palo Alto Device where connected = true`<br>`Palo Alto Device where family = 'PA-5060'` |
| Palo Alto Physical Device | `Palo Alto Physical Device where model = 'PA-5060'` |
| Palo Alto VM Device | `Palo Alto VM Device where model = 'PA-VM'` |
| Palo Alto Device Group | `Palo Alto Device Group where device = <>`<br>`Palo Alto Device Group where address = <>`<br>`Palo Alto Device Group where address group = <>` |
| Palo Alto Service | `Palo Alto service where Port = <>`<br>`Palo Alto service where Protocol = <>` |
| Palo Alto Service Group | `Palo Alto service group where Member = <>` |
| Palo Alto Policy | `Palo Alto Policy where Source vm = <> and Destination vm = <>`<br>`Palo Alto Policy where Source IP = <> and Destination IP = <>` |
| Palo Alto firewall | `Palo Alto firewall where Rule = <>` |
| Palo Alto Zone | `Palo Alto Zone where device = <>` |
| Palo Alto Virtual System | `Palo Alto Virtual System where Device = <>`<br>`Palo Alto Virtual System where Device Group = <>` |

**Note:**
Other than the queries, you can also use facets to analyze the search results.

## Fortinet Search Queries

You can search Fortinet entity details in VCF Operations for networks.

Here are some sample search queries:

| Fortinet Entities | Sample Queries |
|---|---|
| Fortinet Policy Package | `Fortinet Policy Package where Domain Manager = 'ADOM_NAME'` |
| Fortinet Policy | `Fortinet Policy where Source IP = '10.0.0.15'` |
| Fortinet Address | `Fortinet Address where Address Type = 'ipmask'` |

| Fortinet Entities | Sample Queries |
|---|---|
| Fortinet Dynamic Address | `Fortinet Dynamic Address where Domain Manager = 'ADOM_NAME'` |
| Fortinet Dynamic Address Group | `Fortinet Dynamic Address Group where Domain Manager = 'ADOM_NAME'` |
| Fortinet service | `Fortinet Service where port = 5900` |
| Fortinet service Group | `Fortinet Service Group where Manger = '10.0.15.101'` |
| Fortinet ADOM | `Fortinet ADOM where Manager ID = '10.0.15.101'` |
| Fortinet VDOM | `Fortinet VDOM where Domain Manager = 'ADOM_NAME'` |
| Fortinet Dynamic Interface | `Fortinet Dynamic Interface where Domain Manager = 'ADOM_NAME'` |

## Enriching Flows with the Infoblox DNS Data

VCF Operations for networks supports two sources of DNS information:

- Imported CSV file
- Infoblox DNS

**Note:**
If there is a conflict between Infoblox DNS and the CSV file, the information from Infoblox DNS takes precedence.

You can use various search queries to find out more about the source of DNS entries in a flow.

**Table 1336:**

| Keyword | Sample Search Query | Description |
|---|---|---|
| DNS Provider | `Flows where DNS Provider='Infoblox'` | Provides the list of flows in which the DNS data is obtained from Infoblox. |
| DNS Provider | `Flows where DNS Provider='CSV'` | Provides the list of flows in which the DNS data is obtained from CSV. |
| Source DNS Provider | `Flows where Source DNS Provider='Infoblox'` | Provides the list of flows in which the DNS provider for the source IP address is Infoblox. |
| Destination DNS Provider | `Flows where Destination DNS provider='Infoblox'` | Provides the list of flows in which the DNS provider for the destination IP address is Infoblox. |

## Common Search Queries for Kubernetes Entities

You can search for Kubernetes entities details in VCF Operations for networks.

**Common Queries**

- Search Flows : `flows where` *`Kubernetes Object = Object name`*
  Example: flows where *`Kubernetes Cluster = 'Production'`*
- View the service scale: `kubernetes pods group by Kubernetes Services`
- View the node load: `kubernetes Pods group by Kubernetes Node`
- View the node health: `MemoryPressure and PIDPressure and DiskPressure and Ready of Kubernetes Node`

- View flow compliance: `flows from Kubernetes Object` *`name of the object`* `to Kubernetes Object` *`name of the object`*
  Example: `flows from Kubernetes Namespace'`*`PCI`*`' to Kubernetes Namespace'`*`Non-PCI`*`'`
- View the Path topology:
  - Kubernetes service *`service name`* to Kubernetes service *`service name`*
  - Kubernetes service *`service name`* to Kubernetes pod *`pod name`*
  - Kubernetes pod *`pod name`* to Kubernetes pod *`pod name`*

**Table 1337: Queries on Kubernetes Object**

| Kubernetes Object | Query | Description |
|---|---|---|
| Namespace | • kubernetes namespace where L2 Networks = '*a*'<br>• list(Kubernetes Node) of Kubernetes Pod where Kubernetes Namespace = '*a*' | • Return the Kubernetes namespace where it is connected to L2 Network 'a'<br>• Return the list of Kubernetes nodes where Kubernetes namespace is 'a' |
| Pod | • NSX-T Logical port where connectedto.modelKey in (modelKey of kubernetes nodes) order by Tx Packets desc<br>• NSX-T Logical port where connectedto.modelKey in (modelKey of kubernetes pods) and Rx Packet Drops > 0<br>• new kubernetes pod in last 1 hour | • Return the list of logical ports which are connected to a node based on transferred packets in descending order<br>• Return the list of logical ports which are connected to Kubernetes pods and Rx dropped packets > 0<br>• New Kubernetes pods discovered in last one hour |
| Services | • kubernetes pods where kubernetes services is not set<br>• kubernetes pods group by Kubernetes Services, Kubernetes Cluster | • List of Kubernetes pods that does not have a service<br>• Number of pods running on each service |
| Nodes | • kubernetes nodes where Ready != 'True'<br>• kubernetes node where Virtual Machine = 'vm-a' | • List of unhealthy Kubernetes nodes<br>• Kubernetes node that is part of 'vm-a' virtual machine |
| Flows | • flows where kubernetes service is set<br>• flows where source kubernetes node = 'a' | • List of flows where either a source or a destination Kubernetes service exists<br>• List of flows where source Kubernetes node = 'a' or destination Kubernetes node = 'a' |

**Table 1338: Additional Queries**

| Entity/Components | Query | Description |
|---|---|---|
| Applications that have Kubernetes entities | application where virtual member = ‘service-a’ | List of all applications where Kubernetes service ‘service-a’ is a member |
| | application where virtual member = ‘service-a’ and virtual member.Kubernetes Namespace = ‘namespace-b’ | List of all applications where Kubernetes service ‘service-a’ and Kubernetes namespace is ‘namespace-b’ is a member |
| | tier where virtual member = ‘service-a’ and virtual member.Kubernetes Namespace = ‘namespace-b’ | List of all tiers where Kubernetes service ‘service-a’ and Kubernetes namespace is ‘namespace-b’ is a member |
| | count of applications where Virtual Member in (kubernetes services) | The number of applications where member is of type Kubernetes service |
| | count of applications where virtual member in (kubernetes services where Kubernetes Namespace = ‘sock-shop’) | The number of applications where member is of type Kubernetes service which is under Kubernetes namespace ‘sock-shop’ |

| Entity/Components | Query | Description |
|---|---|---|
| | list(virtual member) of applications where Name = ‘app-1’ and virtual member.Kubernetes Cluster is set | List of all the Kubernetes services as members for the application ‘app-1’ |
| Metrics | nsx-t logical port where (ConnectedTo in (Kubernetes Pods where kubernetes cluster is set)) and Rx Packet Drops > 0 group by ConnectedTo order by max(Rx Packet Drops) | Rx Packet drops that are grouped based on Kubernetes pod |
| | nsx-t logical port where (ConnectedTo in (Kubernetes Nodes where kubernetes cluster is set)) and Rx Packet Drops > 0 group by ConnectedTo order by max(Rx Packet Drops) | Rx Packet drops that are grouped based on Kubernetes node |
| | nsx-t logical switch where Rx Packet Drops > 0 and Tag like ‘ncp/project:’ order by Rx Packet Drops | Rx Packet drops that are grouped based on Kubernetes namespace |
| | nsx-t logical switch where Rx Packet Drops > 0 and Tag like ‘ncp/project:<namespace name>’ | Rx Packet drops that are specific to a Kubernetes namespace |
| | nsx-t logical port where (ConnectedTo in (Kubernetes Pods where kubernetes cluster is set)) and Rx Packet Drops > 0 group by ConnectedTo.Kubernetes service order by max(Rx Packet Drops) | Rx Packet drops that are grouped based on Kubernetes services |
| | flows where firewall action = ‘DROP’ group by Kubernetes Service | Drop flows that are grouped based on Kubernetes services |
| | flows where firewall action = ‘DROP’ group by source Kubernetes Namespace | List of all dropped flows that are grouped based on Kubernetes namespace |
| Kubernetes alerts | Kubernetes alerts where Problem Entity = ‘<pod/ namespace/node Name>’ | List of all Kubernetes alerts for the given Kubernetes entity. Kubernetes entity would be either pod or namespace or node |
| | Kubernetes alerts where alert code = ‘ImagePullBackOff’ in last 24 hours | List of Kubernetes alerts of type ‘ImagePullBackOff’ in last 24 hours |
| | Kubernetes alerts where problem entity.Kubernetes Cluster = ‘<cluster-a>’ | List of all Kubernetes alerts for the given cluster |

## Sample Search Queries Related to Load Balancer

To filter or search data related to the load balancer, you can use search queries.

- `vm where lbServiceNodes is set` - Lists all the VMs that are hosting an application where the load is distributed.
- `vm where lbServiceNodes is set and PowerState !='POWEREDON'` - Lists all the VMs that are hosting a load balanced application, but currently non-functional.
- `pool member where state = 'DISABLED'` - Lists all pool members that are deactivated.
- `Count of Pool Members where Service Port = '80'` - Provides the count of all pool members for a particular type of service that are running on port 80.
- `service node where virtual machine is not set` - Lists all service nodes that are using physical servers as application servers. Or, shows the VMware vCenter Server that is hosting multiple VMs, and is not added in VCF Operations for networks.

## Search Queries for NSX Firewall Rules

You can search for NSX Firewall rules in VCF Operations for networks.

**Table 1339: NSX Firewall Rules Queries**

| Search Query | Description |
|---|---|
| `VM where incoming rules.Source Any` | View rules with any source (can combine with a specific port). |
| `Firewall rule where action = allow and service any = true` | View firewall rules that allow any ports. |
| `Firewall Rule Masked Alert` | View the list of unused firewall rules. |
| `New firewall rules in last 24 hours` | View the firewall rules created in the last 24 hours. |
| `New firewall rules in last 7 days` | View the firewall rules created in the last 7 days. |
| `New firewall rules in last 30 days` | View the firewall rules created in the last 30 days. |
| `Firewall rule where flow is not set` | View the list of all inactive firewall rules. |
| `Flow group by firewall rule` | View the count of flows hitting each firewall rule. |
| `Security group where Indirect Incoming Rules is not set and Indirect Outgoing Rules is not set and Direct Incoming Rules is not set and Direct Outgoing Rules is not set` | View the security group that is not used. |
| `Ipset where Indirect Incoming Rules is not set and Indirect Outgoing Rules is not set and Direct Incoming Rules is not set and Direct Outgoing Rules is not set` | View the IPSet that is not used. |
| `Flow where rule id in (1011, 1012, 1013)` | Flows hitting a specific rule ID. |
| `Flow where application = app1` | Flows hitting the application. |

- Unused firewall rules
- Firewall rule Masking rule alert

## Avi Load Balancer Search Queries

You can search Avi Load Balancer entity details and alerts in VCF Operations for networks.

Here are some sample search queries on Avi Load Balancer entities:

| Avi Load Balancer Entities | Sample Queries | Description |
|---|---|---|
| Data Source | `NSX-ALB Data Source where Problem = 'Data Source is not reachable'` | Shows a list of Avi Load Balancer data sources that are not reachable from the collector VM |
| Cluster | `NSX-ALB Cluster where Controller Count < 3` | Shows a list of Avi Load Balancer clusters having less than three controllers |
| Controller | `NSX-ALB Controller group by Manager where CPU Usage Rate > 50 %` | Shows a list of Avi Load Balancer clusters where the CPU usage rate of the controller is greater than 50% |
| Virtual Service | • `NSX-ALB Virtual Service group by Analytics Profile`<br>• `NSX-ALB Virtual Service group by Name order by Active connections`<br>• `NSX-ALB Virtual Service where Operational Status = 'Down'` | • Shows a list of virtual services that are grouped by analytics profile<br>• Shows a list of virtual services that are grouped by active connections<br>• Shows a list of virtual services that are shutdown |

| Avi Load Balancer Entities | Sample Queries | Description |
|---|---|---|
| Service Engine | `NSX-ALB Service Engine where Vnic in (Vnic where Tx Packet Drops > 100)` | Shows a list of service engines where the packet drops of vNIC is greater than 100 |
| Pool Group | `NSX-ALB Pool Group where Cloud = 'nsxt_cloud_overlay'` | Shows a list of pool groups associated with the Cloud `'nsxt_cloud_overlay'`. |
| Pool | `NSX-ALB Pool where Tenant = 'admin'` | Shows a list of server pools associated with the tenant `'admin'`. |
| Analytics Profile | `NSX-ALB Analytics Profile group by Tenant, Manager where Tenant = 'admin'` | Shows a list of analytics profiles that are grouped by the cluster and tenant `'admin'` |

Here are some sample queries on Avi Load Balancer alerts:

| Sample Queries | Description |
|---|---|
| `Alerts where Alert Tags = 'NSX-ALB'` | Shows a list of Avi Load Balancer system alerts |
| `Alerts where Alert Tags = 'NSX-ALB' and Problem Entity = 'nsxt_cloud_overlay-Avi-se-azjyc'` | Shows a list of alerts associated with the entity `'nsxt_cloud_overlay-Avi-se-azjyc'` |
| `Alerts where Alert Tags = 'NSX-ALB' group by Problem Entity` | Shows a list of alerts grouped by Avi Load Balancer entities |

## VMC SDDC Search Queries

You can search the VMware Cloud on AWS SDDC ( Software-defined data center) entity details in VCF Operations for networks.

Here are few sample search queries:

| VMC SDDC entities | Sample Queries | Description |
|---|---|---|
| NSX Manager | `vmc sddc where NSX Manager` | Shows NSX Manager associated with the VMware Cloud on AWS SDDC. |
| NSX Manager FQDN | `vmc sddc where NSX Manager Fqdn` | Shows the NSX Manager FQDN for the VMware Cloud on AWS SDDC. |
| NSX Manager Private Ip | `vmc sddc where NSX Manager Private Ip` | Shows the NSX Manager private IP address for the VMware Cloud on AWS SDDC. |
| NSX Manager Public Ip | `vmc sddc where NSX Manager Public Ip` | Shows the NSX Manager public IP address for the VMware Cloud on AWS SDDC. |
| Name | `vmc sddc where Name` | Shows the name of the VMware Cloud on AWS SDDC. |
| Org Id | `vmc sddc where Org Id` | Shows the organization ID to which the SDDC belongs. |
| Org Name | `vmc sddc where Org Name` | Shows the organization name to which the SDDC belongs. |
| Region | `vmc sddc where Region` | Shows the AWS region where the SDDC is located. |
| VC FQDN | `vmc sddc where VC FQDN` | Shows the VMware vCenter FQDN for the VMC SDDC. |

| VMC SDDC entities | Sample Queries | Description |
|---|---|---|
| VC Manager | `vmc sddc where VC Manager` | Shows the VMware vCenter Manager associated with the VMware Cloud on AWS SDDC. |
| VC Private Ip | `vmc sddc where VC Private Ip` | Shows the private IP address of the VMware vCenter for the VMware Cloud on AWS SDDC. |
| VC Public Ip | `vmc sddc where VC Public Ip` | Shows the public IP address of the VMware vCenter for the VMware Cloud on AWS SDDC |
| Vendor ID | `vmc sddc where Vendor ID` | Shows the ID of the SDDC. |

**Related Topic**

Viewing VMC SDDC Details

You can use the **VMC SDDC** page to get an overview of your VMC on AWS SDDC in VCF Operations for networks.

## VMware NSX-T Manager Search Queries for BGP and ECMP

You can search the VMware NSX-T Manager entity details in VCF Operations for networks.

Here are few sample search queries:

| VMware NSX-T Manager Entities | Sample Queries |
|---|---|
| BGP Neighbor | • BGP Neighbors of a given NSX-T Manager:<br>`list(BGP Neighbor) of NSX-T Router where Manager = 'NSX-T Manager Name'`<br>• BGP Neighbors of a given NSX-T Router:<br>`list(BGP Neighbor) of NSX-T Router 'Router Name'`<br>• BGP Neighbors of a given NSX-T Transport Node:<br>`list(BGP Neighbor) of NSX-T Service Router where Active Node = 'Transport Node Name'`<br>• BGP Neighbor with non active BGP Status:<br>`list(BGP Neighbor) of BGP Connection where BGP Status != 'Active'`<br>• BGP Neighbor with a specific AS number:<br>`BGP Neighbor where Local AS = '64500` |

## AWS Account Search Queries

You can search AWS account entity details in VCF Operations for networks.

Here are few sample search queries:

| AWS Entities | Sample Queries |
|---|---|
| AWS EC2 | `AWS EC2 where Security Group = '' and Account = ''` |
| AWS interface | `AWS Interface where Network address like '' order by Manager` |
| AWS Internet Gateway | `AWS Internet Gateway where AWS VPC = ''` |
| AWS Route | `AWS Route where Account = '' group by Name` |
| AWS Route Table | `AWS Route Table where AWS Subnet = ''` |
| AWS Security Group | `AWS Security Group where Group Name = ''` |
| AWS Subnet | `AWS Subnet where Region = '' group by Vendor ID`<br>`AWS Subnet where Availability Zone = ''` |
| AWS VPC | `sum(bytes) of flows where Source AWS VPC = '' and Destination AWS VPC = ''` |
| AWS VPC Peering Connection | `AWS VPC Peering Connection where Acceptor AWS VPC = ''` |
| AWS VPN Connection | `AWS VPN Connection where AWS Virtual Private Gateway = ''` |

| AWS Entities | Sample Queries |
|---|---|
| AWS Virtual Private Gateway | `AWS Virtual Private Gateway where AWS VPC = ''` |

All the AWS accounts in your organization that are added to the primary account are known as Linked Accounts. For more information, see Primary and Linked AWS Accounts and Add a Primary AWS Account.

Here are few sample queries for linked AWS account discovery:

| AWS Entities | Sample Queries |
|---|---|
| AWS Linked Account | `AWS Linked Account` |
| AWS Direct Connect Gateway | `AWS DX Gateway where ASN = ''` |
| AWS TGW Attachment | `AWS TGW Attachment where Entity Type = 'AWS TGW Attachment'` |

### VMware Cloud on AWS for AWS Entities

Here are the entities related to VMware Cloud on AWS NSX Policy Manager:

- `NSX Policy Manager Data Source`
- `NSX Policy Manager`
- `NSX Policy Firewall`
- `NSX Policy Firewall Rule`
- `NSX Policy Segment`
- `NSX Policy Based VPN`
- `NSX Policy Group`

**Note:**
If NSX-T 2.4 and VMware Cloud on AWS are added as data sources in your VCF Operations for networks, then to get the VMware Cloud on AWS entities, you must add `SDDC type = VMC` filter in your query. For example, to list the Policy Based VPNs for VMware Cloud on AWS, enter `NSX Policy Based VPN where Tier0 = ‘’ and SDDC Type = ‘VMC’.`

Some sample search queries related to the VMware Cloud on AWS entities are:

- `VMs where L2 Network = '' (L2 Network -> NSX Policy Segment)`
- `NSX Policy Based VPN where Tier0 = ''`
- `NSX Policy Based VPN where Local Network = '' (Local Network of Policy Based VPN Rule)`
- `NSX Policy Based VPN where Remote Network = '' (Remote Network of Policy Based VPN Rule)`
- `NSX Policy Group where Translated VM = ''`
- `VM where NSX Policy Group = ''`

**Note:**

- NSX Policy Manager does not support child groups or IPSETS. Hence all the searches like `NSX Policy firewall rule where Indirect __________ = ''` or `NSX Policy group where Indirect _____= ''` are deactivated.

### Search Queries for HCX Mobility Optimized Networking

You can search for HCX Mobility Optimized Networking in VCF Operations for networks

**Table 1340: HCX Mobility Optimized Networking Queries**

| Search Query | Description |
|---|---|
| `VM where MON = 'true'` | View the list of HCX Mobility Optimized Networking enabled VMs. |
| `HCX L2 Extensions where MON = 'true'` | View the list of HCX Mobility Optimized Networking enabled HCX L2 Extensions. |
| `Flows where flow type = 'HCX Mobility Optimized Flow'` | View the list of HCX Mobility Optimized Networking optimized flows. |

## Advanced Queries

Here are some examples for advanced queries:

**Flow Queries for Communication Patterns**

- Total Traffic across data centers or sites (DCI link use)
  `sum(bytes) of flows where ( Dst Manager = 'abc' AND src manager = 'cba') OR ( Dst Manager = 'cba' AND src manager = 'abc')`
- Total VTEP traffic
  - `sum(bytes) of flows where Flow Type = 'Src is VTEP' or flow type = 'Dst is VTEP' VTEP traffic grouped by VMKNIC`
  - `sum(bytes) of flows where Flow Type = 'Src is VTEP' or Flow Type = 'Dst is VTEP' group by ip`
- Other Management Traffic
  `flows where Flow Type = 'Source is VMKNIC' or Flow Type = 'Destination is VMKNIC'`
- Flows for extended L2 network
  `flows where flow type = 'Extended L2 Network' and Destination IP Address = 10.172.13.14`

**Flow Queries for Aggregation and Grouping**

- Total Internet traffic by Source VM
  `sum(bytes) of flows where Flow Type = 'Internet' group by src vm`
- Top ports by total bytes
  `sum(bytes) of flow group by port order by sum(bytes)`
- Top subnet pairs by routed traffic volume
  `sum(bytes) of flow where Flow Type = 'Routed' group by Source Subnet Network, destination subnet network order by sum(bytes)`
- Total VM by total pair bytes
  `sum(bytes) of flows group by src vm , dest vm order by sum(bytes)`
- Top Server VM/Port by total bytes
  `sum(bytes) of flows group by dest vm , port order by sum(bytes)`

**Flow Queries for Capacity Estimation and Sizing**

- Total bytes of all `vm-internet/internet-vm` traffic grouped by ESX ( Palo Alto Service VM sizing)
  `sum(bytes) of flows where flow type = 'internet' and (flow type = ' src is vm ' OR flow type = 'destination is vm ') group by host order by sum(bytes)`
- Aggregated traffic series for matching flows ( Palo Alto Service VM sizing)
  `series( sum(byte rate)) of flows where host = 'ddc1-pod2esx012.dm.democompany.net' and (Flow Type = 'Source is VM' OR flow type = 'Destination is VM')`

**Useful Queries for Application**

- VMs in a given application
  `VM where application = 'CRM'`
- Routed Flows from a given application
  `Flows where source application = CRM and Flow Type = 'Routed'`
- Flows between two tiers (one-way)
  `Flows where src tier = 'App' and Destination Tier = 'DB'`
- Flows between two tiers (one-way)
  `Flows where ( src tier = 'App' and destination Tier = 'DB') OR (destination tier = 'App' and source tier = 'DB')`

**Useful Queries for VM and ESX**

- Properties of Prod -Midtier-1 VM (MAC, IP, host, and so on)
  `CPU Usage Rate, Network Rate, Memory Usage Rate, mac address, ip , vxlan , host of vm 'Quality control-VM26'`
- Network segments having the highest VM count
  `vm group by l2 network`
- Datastores have highest VM count
  `vm group by datastore`
- Hosts by vSphere version
  `host group by version`
- Hosts by vSphere Builds
  `host group by OS`
- All VMs on all host/blade slotted in a particular UCS chassis (Nested Query)
  `vm where host in (host where Blade like 'sys/chassis-1')`

**Useful Queries: General Capacity**

- Number of Datacenters:
  `count of datacenter`
- Number of clusters
  `count of cluster`
- Number of Hosts
  `count of host`
- Number of VMs
  `count of vm`
- Number of Networks
  `count of vlan`

**Useful Queries: Routes**

- VNIs by Primary controller
  `vxlan group by Primary Controller`
- Routes for Provider edge 3
  `routes where vrf = 'Provider Edge 3'`
- Routes of DMZ DLR
  `NextHop Router of routes where VRF = 'LDR-DMZ'`
- Routes having the given router as next hop
  `routes where NextHop Router = 'California-Edge'`

**Useful Queries: Firewall Rules**

- Firewall rules between two VMs

```
firewall rules from 'Prod-Midtier-1' to 'Prod-Db-1'
```

- Rules with have `ANY` source

  ```
  firewall rules where Service Any = true
  ```
- VMs for a given rule

  ```
  vm where Firewall Rule = 'Prod MidTier to Prod DB - DBService '
  ```
- Firewall rules where any port is allowed

  ```
  firewall rule where action = allow and service any = true
  ```
- Flows hitting a particular firewall rule

  ```
  flows where firewall rule = 'Admin to Prod and Lab - SSH'
  ```
- Denied flows in the system

  ```
  flows where firewall action = deny
  ```
- View gateway firewall

  ```
  Firewall Rule where firewall type = 'GatewayFirewall'
  ```
- View distributed firewall

  ```
  Firewall Rule where firewall type = 'Distributed Firewall'
  ```

**Useful Queries: General Traffic Patterns**

- East-West and North-South traffic count, switched traffic count, routed traffic count, and VM to VM traffic count

  ```
  plan security in last 7 days
  ```

**Useful Queries: Traffic from a security lens**

- Top talkers VMs details

  ```
  top 7 vm group by name, Vlan order by sum(Total Network Traffic) in last 7 days
  ```
- Networks that carry the most traffic

  ```
  top 7 vlan group by Vlan id, vm count order by sum(Total Network Traffic) in last 7
  days
  ```
- Networks where most of the communication is within the VLAN (not crossing a physical firewall or L3 boundary)

  ```
  top 7 flow where Flow Type = 'Switched' group by Subnet Network order by sum(Bytes) in
  last 7 days
  ```
- Networks where most of the communication is across VLAN (may be causing bottleneck problems at physical firewall)

  ```
  top 7 flow where Flow Type = 'Routed' group by Source Subnet Network, Destination
  Subnet Network order by sum(Bytes) in last 7 days
  ```
- VMs that talks outside the country

  ```
  top 7 flow where Destination Country != 'United States' group by Source VM, Destination
  Country order by sum(Bytes) in last 7 days
  ```
- Data stores experiencing the most storage latencies

  ```
  avg(Read Latency), avg(Write Latency) of top 7 vm group by Datastore, vlan order by
  avg(Write Latency) in last 7 days
  ```

**Useful Queries: Compliance/Vulnerabilities**

- Vulnerable OSs details

  ```
  vm where Operating System like 'Microsoft Windows Server 2003' or Operating System like
  'Microsoft Windows Server 2008' or Operating System like 'Red Hat Enterprise Linux 6'
  or Operating System like 'Red Hat Enterprise Linux 5' or Operating System like 'SUSE
  Linux Enterprise 10' group by vlan, Operating System
  ```
- Vulnerable OS Count

  ```
  count of vm where Operating System like 'Microsoft Windows Server 2003' or Operating
  System like 'Microsoft Windows Server 2008' or Operating System like 'Red Hat
  Enterprise Linux 6' or Operating System like 'Red Hat Enterprise Linux 5' or Operating
  System like 'SUSE Linux Enterprise 10'
  ```
- Total attack surface due to Old OSs

```
vm where vlan in (vlan of vm where os in ('Microsoft Windows Server 2003', 'Microsoft Windows Server 2008', 'Red Hat Enterprise Linux 6', 'Red Hat Enterprise Linux 5', 'SUSE Linux Enterprise 10')) group by Vlan
count of vm where vlan in (vlan of vm where os in ('Microsoft Windows Server 2003', 'Microsoft Windows Server 2008', 'Red Hat Enterprise Linux 6', 'Red Hat Enterprise Linux 5', 'SUSE Linux Enterprise 10'))
```

**Note:**
To get recommended firewall rule for the vulnerable OS, see Recommended Firewall Rule to Secure Vulnerable OS.

## Time Control

Time-control allows you to run a search query within the context of a selected time or time range. You can select from a list of presets such as last 24 hours, last 3 days, and so on. You can also specify a particular date and time using the **At** option or even a range using the **Between** option.

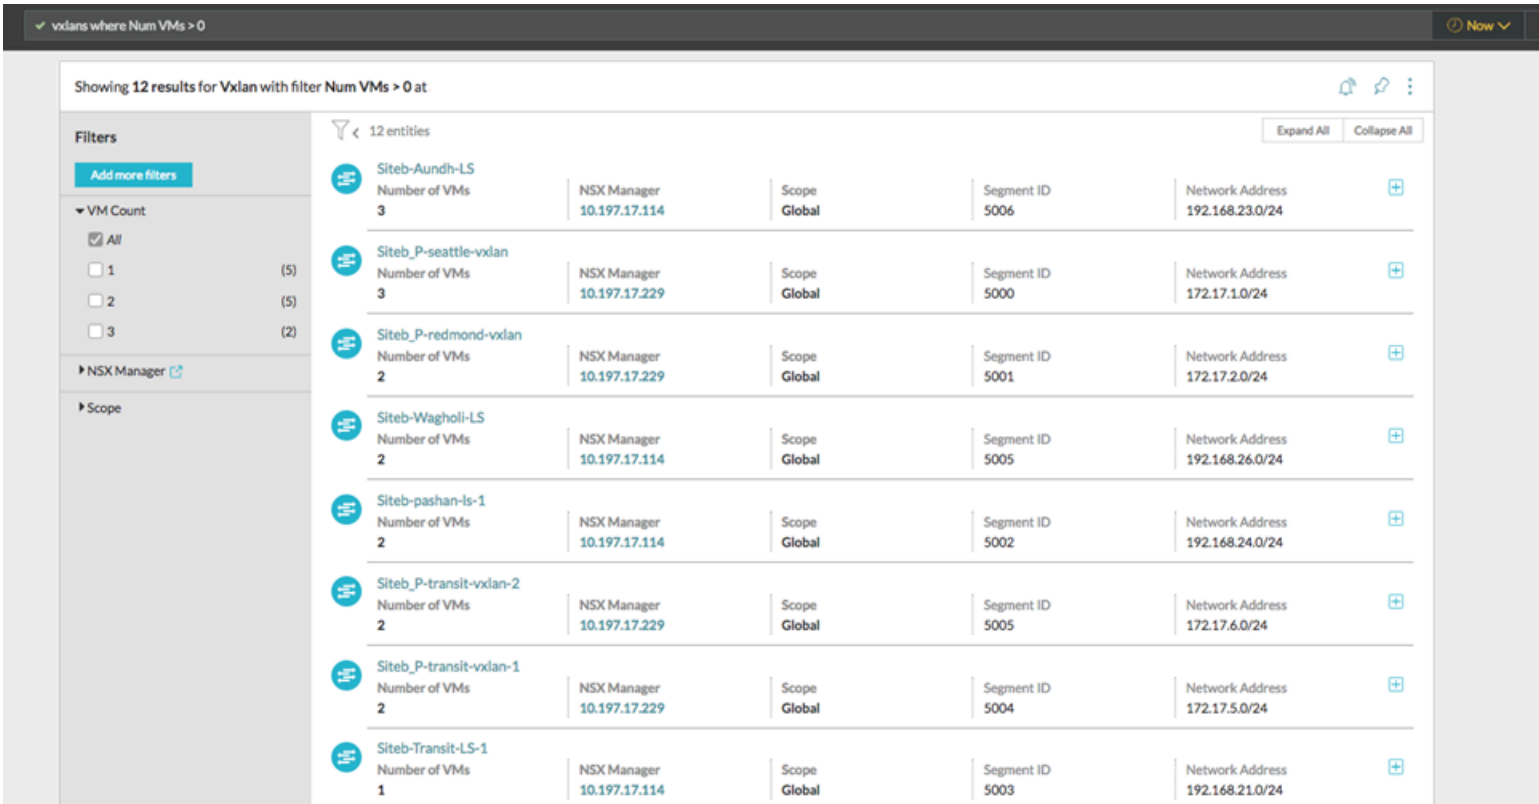
## Search Results

The search results page provides a detailed list of concerned entities that match a particular search. The page itself provides numerous information that ranges from the list of entities, their corresponding properties, and facets to filter the search results to refine your search.

You can also expand or collapse each entry in the search results to view more information about a particular entry. You can also create a notification for each search.

**Note:**
You can point to a particular property in the search results and also in the entity pages to view a tool tip containing more information about that property.

The following graphic shows the search results for the VXLANs where `num vms > 0` search query for a time from the past.



## Filters

When you get the search results, click **Add more filters** on the left pane as per your requirements. You can view a series of filter categories that you can use to narrow down the search results. The number of available filters for each category is mentioned in a small box beside the category.

View the available filters for that category (along with a short explanation for each filter) and click to apply that filter. You can also use the filter search box to search for a particular filter and VCF Operations for networks automatically shows the filters that match your search query and you can click to apply that filter.

Each filter has several properties to refine the search results. When you select a filter property from one of the filters, then the selected property is highlighted in the search results.

## VMware vCenter Tags

VCF Operations for networks provides VMware vCenter tags for search and planning.

You can perform a search of VMs based on the VMware vCenter tags and custom attributes. For example, you can use the following query for search VMs by using tags:

```
vm where tag = '{keyname}:{value}'
```

Every tag belongs to a category. In this example, the keyname is the category to which the tag belongs and value is the name of the tag.

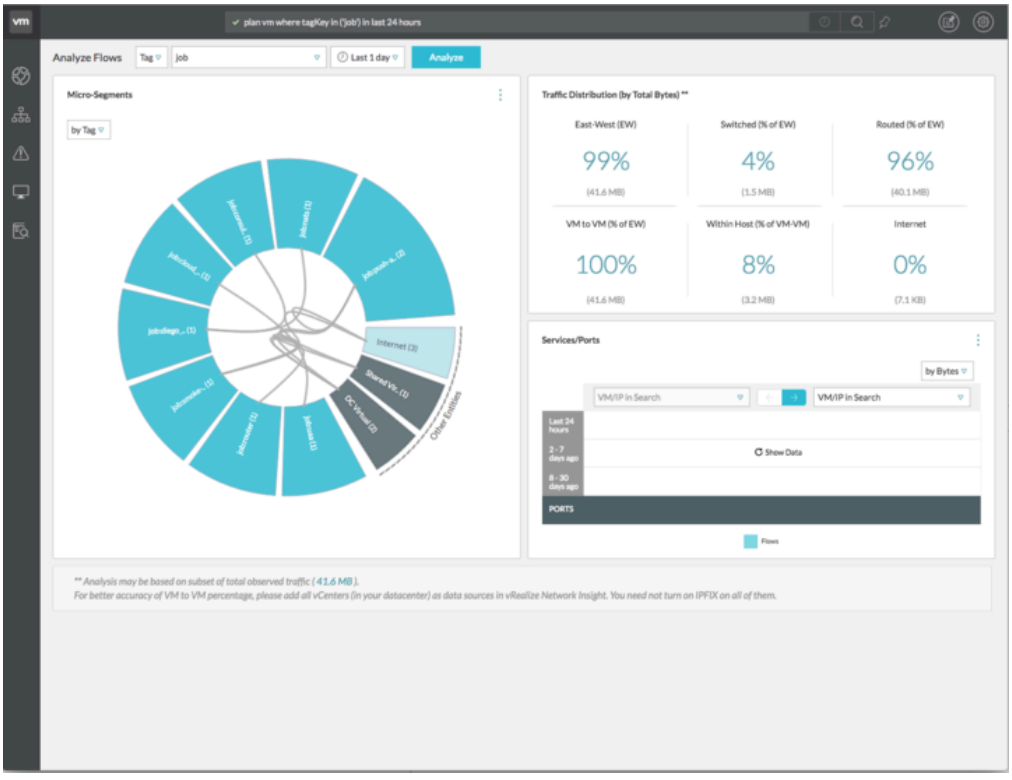
You can also provide an alternate name to a VM by using VMware vCenter tags or custom attributes by using the `name` key. This alternate name is shown as the `other names` property. It is also possible to search and make path queries using the alternate name.

For example, the following queries are supported:

```
vm "other-name-1"
        vm "other-name-1" to vm "other-name-2"
```

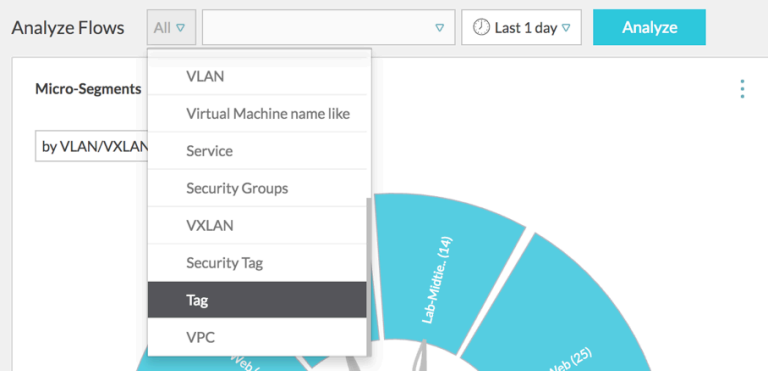
In this example, `other-name-1` and `other-name-2` are custom attributes with the `name` key or tags belonging to the `name` category.

You can also analyze the flows in the network by using the VMware vCenter tags as shown in the figure.

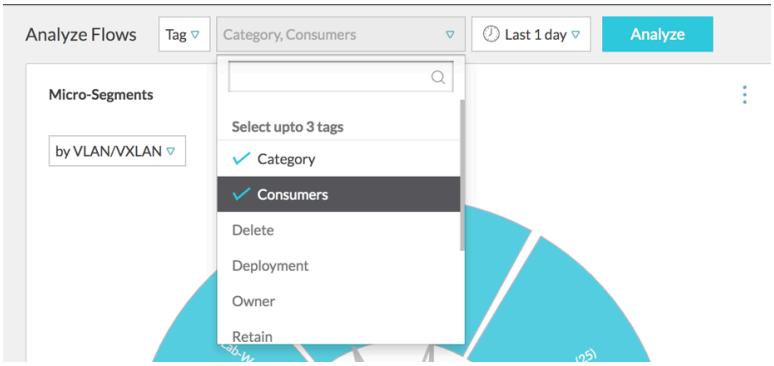


### Using VMware vCenter Tags

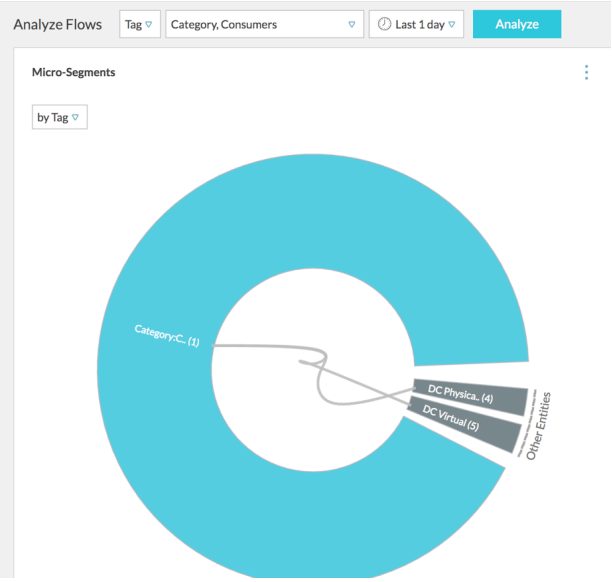
To use the VMware vCenter tags, select the **Tag** option from the **Analyze Flows** drop-down menu.



You can also select up to three tags at this level. After you select the tag, click **Analyze**.



In **Group by Criteria**, **Tag** is selected.



## Working with the Streaming Databus

The databus is a framework for sharing the data stored in VCF Operations for networks with other applications using APIs. With the databus, you can share high volumes of data with low latency in near real-time.

VCF Operations for networks databus provides the following benefits:

- Provides a way to programmatically consume high-volume data in near real-time.

- Works on a change-based consumption model which gives databus a distinct advantage over traditional API calls, especially in the context of high-volume data like flows and metrics.

## Use Cases

With VCF Operations for networks databus, you can use the data for various purposes. Following are a couple of examples of how you can use the databus:

| Use case | Description | Steps |
|---|---|---|
| Retain flows for a longer duration | In general, flow retention in VCF Operations for networks is one month.<br>With the databus, you can retain flows for a longer duration. | 1. Set up a subscriber URL to receive HTTPS/HTTP data.<br>2. Ensure you are aware of the required security information. For more information, see the *Know about the Security and SSL Certificate* section.<br>3. Register a subscriber to subscribe flows to the message group.<br>4. Data starts streaming. For more information on message format, see the *Message Format Received from the Databus* section.<br>5. To learn more about the databus capabilities, see Understanding the Databus Terminologies and Capabilities. |
| Sending alerts to various destinations | By defaults, you can send alerts to SNMP / SMTP destinations.<br>With databus, you can send alerts to various other destinations, such as Slack, ServiceNow, PagerDuty, and so on.<br>A few examples of alerts that you can get using databus are system alerts for password expiry, VMware vCenter disconnected, and so on. | 1. Set up a subscriber URL to receive HTTPS/HTTP data.<br>2. Ensure you are aware of the required security information. For more information, see the *Know about the Security and SSL Certificate* section.<br>3. Register a subscriber to subscribe flows to the message group.<br>4. Data starts streaming. For more information on message format, see the *Message Format Received from the Databus* section.<br>5. To learn more about the databus capabilities, see Understanding the Databus Terminologies and Capabilities. |
| Streaming metrics out of VCF Operations for networks | Polling APIs for metrics is a multi-step process that includes getting entity IDs, periodically calling the APIs, and filter out duplicate information.<br>The databus makes this entire process very efficient; you subscribe to the metrics group or sub-group of your choice, and the metrics directly gets stream out to the endpoint as the metrics get processed. | 1. Set up a subscriber URL to receive HTTPS/HTTP data.<br>2. Ensure you are aware of the required security information. For more information, see the *Know about the Security and SSL Certificate* section.<br>3. Register a subscriber to subscribe flows to the message group.<br>4. Data starts streaming. For more information on message format, see the *Message Format Received from the Databus* section.<br>5. To learn more about the databus capabilities, see Understanding the Databus Terminologies and Capabilities. |

## Supported Message Groups

The databus streaming is a better alternative to APIs if you are looking to poll information periodically. And to receive information from databus, you must subscribes to message group(s). A message group is a specific set of data that

you can subscribe from the databus. Each message group can have up to 10 subscribers, except for Flows and Metrics message groups which can have only one subscriber per message group. Also, the Metrics message group can have only one subscriber per message group.

VCF Operations for networks supports the following message groups:

| Message Group | Sub-message Group | Message Details |
|---|---|---|
| Metrics | vms-metrics | Metric, interval, time stamp, unit, entity type, and points. |
| | hosts-metrics | Metric, interval, time stamp, unit, entity type, and points. |
| | flows-metrics | Metric, interval, time stamp, unit, entity type, and points. |
| | nics-metrics | Metric, interval, time stamp, unit, entity type, and points. |
| | switchports-metrics | Metric, interval, time stamp, unit, entity type, and points. |
| | nsxt-metrics | Metric, interval, time stamp, unit, entity type, and points. |
| Applications | N/A | Entity ID, entity type, name, created by, creation time, last modified by, last modified time, source, tiers, and discovery info. |
| Flows | N/A | Source VM, destination VM, source IP, destination IP, port, source folders, destination folders, protocol, source IP sets, destination IP sets, source security groups, destination security groups, traffic type, source security tags, destination security tags, source VM tags, destination VM tags, within host, firewall action, firewall rule ID, source managers, destination managers, and flow tag. |
| Problems | N/A | Entity ID, entity type, name, anchor entities, message, event tags, admin state, archived, event time epoch ms, event type, and severity. |

**Table 1341: Configuration-related Message Group**

| Message Group | Message Details |
|---|---|
| VMs | Entity ID, name, entity type, IP addresses, default gateway, default gateways,VNICs, source firewall rules, destination firewall rules, VM UUID, manager UUID, cluster, resource pool, host, vendor ID, vCenter manager, folders, datastore, data center, source inversion rules, destination inversion rules, CPU count, memory, OS full name, and HCX info. |
| Hosts | Entity ID, name, entity type, VMKNICs, cluster, vCenter manager, VM count, datastore, service tag, vendor ID, maintenance mode, connection state, CPU count, memory, and manager UUID. |
| NICs | Entity Id, name, entity type, VLAN, and VM. |

| Message Group | Message Details |
|---|---|
| Switchports | Entity ID, name, entity type, operational status, administrative status, sub type, device, and manager. |

**Tip:**
A sub-message group provides more fine-grained information. All subscribers to a particular message group receive the same information.

The data published over databus is categorized into different message groups. As a user you can subscribe to one or more message groups, and data related to those message groups starts streaming to HTTP or HTTPS endpoints.

Use the following steps to configure the databus:

### 1. Know about the Security and the SSL Certificate

While using the databus, you must be aware of the following security information:

| Environment | Details |
|---|---|
| On-prem | • HTTP/HTTPS as a transport protocol - When using databus for on-prem environment, you can get data from the databus over HTTP / HTTPS endpoint. To ensure that the data is encrypted during transport and verification of subscriber authenticity, use HTTPS.<br>• Firewall Rules - To ensure only VCF Operations for networks can send data to the subscriber, you need to enable the firewall rules. All the VCF Operations for networks platform nodes in a cluster send the data to the subscriber, so you must configure the firewall rules to allow traffic from all the platform nodes.<br>• SSL Certificates - The SSL certificates used by the subscribers must be signed by well-known CAs. If the SSL certificates are self-signed or signed by internal CAs of the organization and not trusted by Java, you must import the CA certificate to the Java trust store of VCF Operations for networks. Contact VMware support to get help on how to import the Java trust store.<br>**Note:**<br>The CA certificate that is imported to the trust store will be trusted for all outgoing SSL traffic from VCF Operations for networks platforms. |
| SaaS | • HTTPS as a transport protocol - When using databus for a SaaS environment, you can get data from the databus only over HTTPS endpoints.<br>• CSP token for message authentication - Each databus message from VCF Operations for networks (SaaS) contains an authorization header with a JWT token issued by CSP. You as a subscriber can verify the authenticity of the token by validating the token with the public key from CSP (`https://console.cloud.vmware.com/csp/gateway/am/api/auth/token-public-key`). You can verify the authenticity of the token to ensure that the client ID in the token is the client ID of the VCF Operations for networks databus application registered on CSP. You get the client ID details from VCF Operations for networks Databus developers.<br>• SSL Certificates - The SSL certificates used by the subscribers must be signed by well-known CAs. By default the SSL certificates that VCF Operations for networks (SaaS) issues are signed by JDK. VCF Operations for networks (SaaS) doesn't support the import of custom CA certificate. |

### 2. Register, Update, or Delete a Subscriber

- To register a subscriber, you must do an API call using the POST method. For details, see the API Reference.
  If the registration is successful, the message response contains a subscriber ID. You can use the subscriber ID to delete a subscription or update a subscription. After successful subscriber registration, it may take up to five minutes for the subscriber to start receiving messages.
- To update a subscriber, you must do an API call using the PUT method. For details, see the API Reference.

  **Note:**
  You can only update the Subscriber URL. You cannot update the `message group`.
- To delete a subscriber, you must do an API call using the DELETE method. For details, see the API Reference.
  After successful subscriber deletion, it may take up to five minutes for the data publishing to stop.

### 3. Message Format Received from the Databus

The messages received as part of various message groups are a list of multiple messages and have a common high-level structure. Each message in the list is a cloud-event formatted object. To learn more about cloud events, see cloudevents.

All the message has two sets of specific fields:

- Common structure - which is common across all the message group. For example:

```
 "id": "14cfd27c-76d8-43e3-9fe9-f53bf69c0c5e",
     "type": "Application",
     "specversion": "1.0",
     "source": "CAESBkFCQ0RFRg==",
     "messageGroup": "applications",
     "status": "CREATE",
```

- Message group-specific structure - which is unique for every message group. For example, the following is the data object within an application message which is unique to the application message group:

```
    "data": {
      "entity_id": "1:561:0",
      "entity_type": "APPLICATION",
      "name": "app1",
      "created_by": "test@vnera.com",
      "creation_time": 1637303575039,
      "last_modified_by": "test@vnera.com",
      "last_modified_time": 1637303575039,
      "source": "MANUAL",
      "tiers": [
        {
          "entity_id": "1:562:1",
          "entity_type": "TIER",
          "name": "app1_t1"
       }
      ]
    }
```

The structure of the objects within databus messages is in line with the schema of public API responses, except for the metric where a subset is in use. The message structure is backward compatible across different versions of VCF Operations for networks. In the later versions, new fields may get added.

The following table lists the names of the different types of messages for every message group:

| Message groups | Type or Schema of the message |
|---|---|
| Alerts (problem events only) | Entity Message List |
| Applications | Application Message List |
| flows | Flow Message |

| Message groups | Type or Schema of the message |
| --- | --- |
| metrics | The structure of the metrics data is different from the public APIs to make the messages compact.<br><pre>[<br>  {<br>  "id": "string",<br>  "type": "string",<br>  "specversion": "string",<br>  "source": "string",<br>  "message_group": "metrics",<br>  "data": {<br>  "metric": "string",<br>  "interval": 0,<br>  "timestamp": 0,<br>  "unit": "string",<br>  "entity_type": "string",<br>  "points": [<br>  {<br>  "entity_id": "string",<br>  "value": 0<br>  }<br>  ]<br>  }<br>  }<br>]</pre> |

For more information on the above objects and message groups, see the API Reference.

## Understanding the Databus Terminologies and Capabilities

The databus provides various capabilities, and understanding these capabilities helps you use the databus more efficiently.

### Subscriber

A subscriber is an endpoint that registers with the databus to receive the data from the message group. You cannot have multiple subscribers with the same message group and the same Subscriber URL.

### Subscriber URL

An URL where you receive the data from the databus. VCF Operations for networks databus sends all the messages from any message group to the subscriber URL. You can also use a subscriber URL to subscribe to multiple message groups.

> **Note:**
> Databus starts streaming date from the moment you subscribe to any message group and will continue until you unsubscribe. The system handles any temporary loss of communication through inbuilt mechanisms and data streaming resumes once the issue is resolved. You don't need to take any action.

### Messages Ordering

The messages sent over the databus are generally ordered by the timestamps when the event or the object is stored in VCF Operations for networks. But, in certain scenarios these ordering guarantees cannot be met. For reliable ordering of the messages, the subscribers must make use of the timestamp field in the Databus messages and sequence the message based on the timestamp.

### Near Real-time Streaming

In the databus, there is a delay between data getting processed in VCF Operations for networks and the databus streaming the data out. The delay could range from three seconds up to one minute. This delay varies based on the message groups and is subject to the pipeline being clear.

### Load Balancer to Scale Data Processing

While receiving data from VCF Operations for networks databus, you can use a load balancer to horizontally scale the data processing service. To use a load balancer, you must use the load balancer URL as the subscriber URL during the databus registration process. A load balancer can distribute the data to a horizontally scalable data processing services.

### Heartbeat

To help troubleshoot the communication channel between VCF Operations for networks databus and the subscriber endpoint, VCF Operations for networks sends hourly heartbeat messages to every subscriber. If a URL is specified in more than one subscription, then the subscriber receives one heartbeat message for every subscription.

Example:

```
{
  "id": "c2214eea-68a6-4e5a-9e4b-ff5886a42cd3",
  "type": "HEARTBEAT",
  "specversion": "1.0",
  "source": "CL58EgdESzVDSEE1",
  "message_group": "vms",
  "status": "HEARTBEAT",
  "timestamp": 1681897371522
}
```

### Message batching

VCF Operations for networks databus inherently supports batching where several messages are grouped together in a batch and sent to the subscriber. By default, the maximum size of a batch is two megabytes. When size of a single message is more than two megabytes then the message is trimmed.

> **Note:**
> The batch creation creates an additional delay which is less than a minute.

Example of a trimmed message:

```
[
{
"id": "elfcdccb-c06a-419b-90bd-7618e8453f87",
"type": "Application",
"specversion": "1.0",
"source": "CNaBARIHRElXRlgxRg==",
"message_group": "applications",
"status": "UPDATE_TRIMMED",
"data": {
"entity_id": "16598:561:716945762559381432", "entity_type": "Application",
"name": "My-3Tier-App"
}
]
```

### Delivery Guarantee

A message delivery is considered successful if the subscriber responds with an HTTP code other than the 503 error code.

If a subscriber doesn’t receive a message, but VCF Operations for networks doesn't get a 503 error code, VCF Operations for networks considers the message as delivered and does not try to send the message again, and the message might get lost. We have introduced this mechanism to ensure that a continuous retry does not overwhelm

your system. For example, If your production environment is down, continuous retries would be very noisy. In this case, sending an HTTP response other than 503 is a way for you to indicate that you do not want to retry.

In VCF Operations for networks, the messages are sourced by different services and then get added into a disk-based queue. The disk-based queue has an expiry of two hours.

Any message if not delivered to the subscriber within two hours, those messages get deleted from the queue in a FIFO manner, and doesn't get delivered to the subscriber. Also, if the volume of the messages in VCF Operations for networks is beyond what can be reliably forwarded by the system, messages may get dropped. When the databus subscriber is unreachable, the system tries to send messages until it delivers the message successfully. A back-off mechanism is added in version 6.9, where the system retries message delivery in exponential time.

#### Filtering

When you register a subscriber, the subscriber gets all the messages of that message group. VCF Operations for networks databus does not support Filtering of messages. If you don't want all the messages in a message group, you can discard the messages based on the filtering conditions before further processing. You can also deactivate alerts from the VCF Operations for networksUI.

#### Correlating messages with Other Objects

In certain scenarios, the messages received by the databus contain contextual information about a few other related entities without the full details of those entities. But, the message contains a specific identifier such as an `entity_id`. To get details about those related entities, you must subscribe to those entities using APIs. For example, subscribing to a host message group can help to correlate the hosts of the events received from the problems message group.

## Planning Disaster Recovery for VCF Operations for networks

VMware Live Recovery is a disaster recovery automation software that provides policy-based management, non-disruptive testing, and automated orchestration. To protect your VCF Operations for networks, VMware Live Recovery automates every aspect of applying a disaster recovery plan to accelerate recovery and eliminate the risks involved when using a manual process.

The prerequisites for the disaster recovery operation for VCF Operations for networks are as follows:

- Ensure that you have installed and configured vSphere Replication.
- VMware Live Recovery should be deployed and configured on both the protected and the recovery sites.
- Ensure that the site pairing is configured properly from within the VMware Live Recovery UI before proceeding with the creation of the recovery plan and other components.
- VMware vSphere Replication should be enabled for each of the protected nodes of the VCF Operations for networks setup in context. While enabling VMware vSphere Replication, provide sufficient RPO considering the VCF Operations for networks node size and usage so that minimum data loss is expected to incur during a disaster.
- Ensure that you create a separate protection group for VCF Operations for networks. For small and non-distributed deployments, ensure that all the VMs are in the same protection group. For distributed deployments, it is recommended that you place all the platforms in a single protection group so that it is easy to recover. You can place the collectors in different protection groups.
- Create a recovery plan and add the protection groups containing VCF Operations for networks VMs to this plan. Ensure that the protection group containing the platform nodes get the higher precedence. In the recovery plan, ensure that the primary platform node is placed in a higher priority group than the other platform nodes.
- Currently, any type of IPv4 customization with VMware Live Recovery is not supported

It is recommended that you migrate or recover VCF Operations for networks VMs to an identical network configuration. Also as per the VMware Live Recovery recommendation, you can perform test run periodically to ensure the existing plan works with underlying infrastructure and the configured RPO limit.

- Migrate or recover VCF Operations for networks VMs to an identical network configuration.
  If the recovery site is configured to have the same network configuration as the protected site and a mapping is created between the identical networks, configure all replicated VCF Operations for networks virtual machines to be

started with the same IPs, because these VMs are the protected nodes. The recovered system will become operational after the planned migration or disaster recovery has finished successfully.

- Do not specify any IP customization for a recovery plan when the recovery site does not have the same network as that of the protected site. In this scenario, VMware Live Recovery is used for the recovery of the appliance VMs. For configuring network post recovery, manually assign the network settings as follows:

1. Run `change-network-settings` command on all platforms to change the IP.

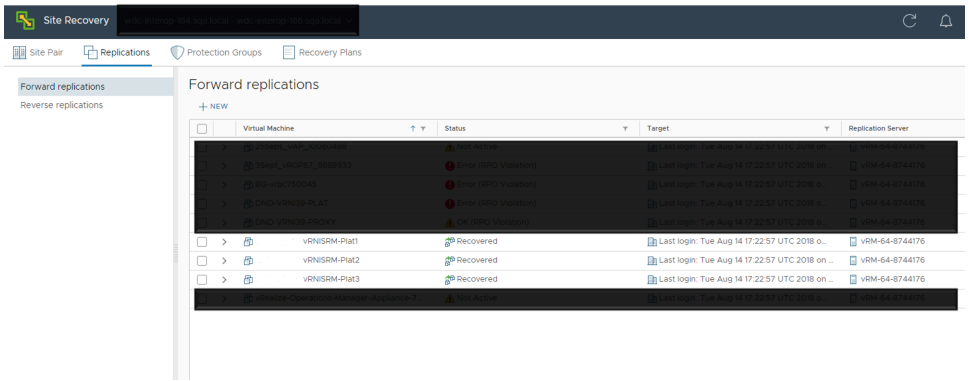
   **Note:**
   Ensure that the platform VM reboots successfully before you run the next command.
2. Run `update-IP-change` command on all the nodes.
   For example, in a 3-node cluster, to update IP of platform1 from IP1 to IP2, run the `update-IP-change` command on platform2 and platform3 with IP1 and IP2 as the arguments. To update IP of platform2, run the `update-IP-change` command on platform1 and platform3.
3. Run `finalize-IP-change` command on platform1.
4. Run the `show-connectivity-status` command on all the collectors and search for `Platform_VM_IP/URL` to identify the associated platform nodes.
5. Run `pair-collector set-platform --ip-or-fqdn platform-newIP` on all collectors.
   For example, if the CollectorA is associated to platform2, run `pair-collector set-platform --ip-or-fqdn platform2-newIP`.
6. Check the service status. If some of the services on the platform nodes are not running, reboot the nodes in the recommended order.

   **Note:**
   For more information on the commands mentioned above, see *VCF Operations for networks Command Line Reference Guide*.

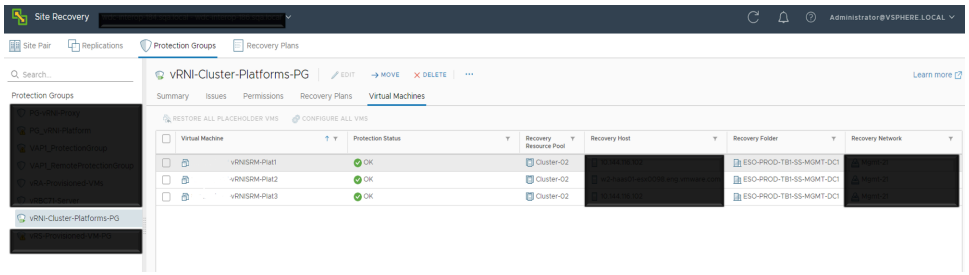
## Sample Disaster Recovery Scenario

Here are the steps for a sample scenario for VCF Operations for networks Disaster Recovery (DR):

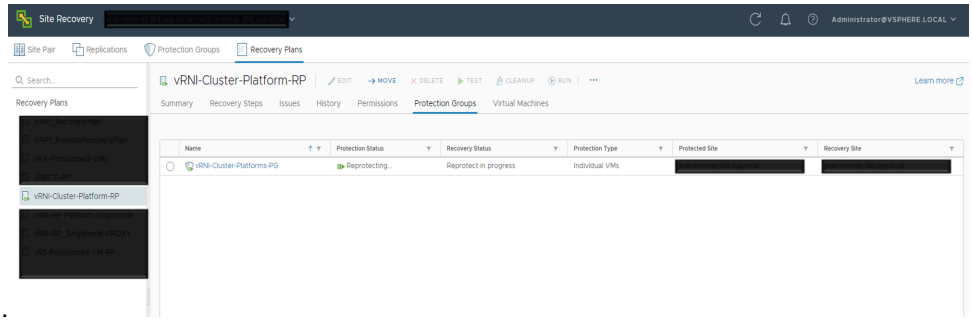
1. Ensure that VMware Live Recovery is configured and up in both the protected and the recovery sites.
2. Configure replication for each of the VCF Operations for networks nodes that are to be protected. While configuring the replication, provide adequate Recovery Point Objectives (RPO) time for the VCF Operations for networks instance. For example, if it is a VCF Operations for networks deployment with a single platform and collector nodes (medium size), then RPO of 45 minutes is good. But if it is a cluster with nodes having bricks of large size, then the adequate RPO should be provided. The snapshot interval configuration is specific to the user environment and requirements.



3. Create a protection group. Include the VMs that you want to protect under a specific protection group.



4. Create the recovery plan where you include the respective protection groups.



5. Perform test recovery. This is to ensure that your recovery plan works as expected.
6. VMware Live Recovery recommends that users perform planned migration at regular intervals to validate the integrity of the existingDR plan.
7. Suppose the recovery site has a network configuration that forces the VCF Operations for networks VMs to come up with the new IPs. Recover the VCF Operations for networks VMs with a recovery plan that assumes no network change for the recovered VMs. Once the recovery of the VMs is reported as a success, in VCF Operations for networks, assign new IP addresses manually to the VCF Operations for networks nodes, apply new certificates, and re-initialize the cluster.
8. As IPv4 customization with VMware Live Recovery is not supported currently, as a work around you can perform DR with VCF Operations for networks assuming as if there is no network change.

   To manually assign the network settings:

   1. Run the `change-network-settings` to change the IP simultaneously on all platforms.
   2. For every platform whose IP is changed, run `update-IP-change` command on all the other nodes.
      For example, for the IP change of platform1 from IP1 to IP2, run the `update-IP-change` command on platform2 and platform3 with IP1 and IP2 as the arguments. For the IP change of platform2, run the `update-IP-change` command on platform1 and platform3.
   3. Run `finalize-IP-change` command once on platform1 after step1 and step 2 are completed.
   4. Run `pair-collector set-platform --ip-or-fqdn <with-updated-ip-of-Platform1>` on the collector node.
   5. Check the service status. If some of the services on the platform nodes are not running, reboot the nodes in the recommended order.

## VMware Transit Connect Support in VCF Operations for networks

An SDDC group uses VMware Managed Transit Gateway (VTGW) to provide high-bandwidth, low-latency connections between SDDCs in the group and to other VPCs in the same region. You can also add a Direct Connect Gateway (DXGW) to provide centralized connectivity to your on-premises SDDCs.

An SDDC group is a logical entity designed to simplify management of your organization's VMware Cloud on AWS resources at scale. Collecting SDDCs into an SDDC group provides a number of benefits to an organization with multiple SDDCs whose workloads need a high-bandwidth, low-latency connection to each other. All network traffic between group members travels over a VTGW network. Routing between compute networks of all SDDCs in a group is managed automatically by VTGW as subnets are added and deleted.

The data source requirements to support VMware Transit Connect are:

| Data Source | Entites | Permissions |
|---|---|---|
| VMC NSX | SDDC group, VTGW, SDDC attachments, VTGW route table, and VTGW routes | Administator |
| AWS account with native VPCs | AWS TGW attachment | EC2 API permissions |
| AWS account with DXGW | DXGW and DXGW associations | EC2 API permissions and Direct Connect permissions |

VTGW support in VCF Operations for networks includes:

- VMC SDDC Group as a search query to view the SDDC group details in the VMC SDDC Group page.
- VMware Transit Gateway as a search query to the view the VTGW details in the VMware Transit Gateway page.
- Search and view details of the related entities like VTGW routes, route tables, and VTGW attachments.
- Flows for:
  - SDDC to SDDC via VTGW.
  - SDDC to native AWS VPC via VTGW.

VTGW support in VCF Operations for networks does not include:

- Flows between VMC SDDC and on-premise SDDC via VTGW and Direct Connect Gateway.
- VM-VM path visualization between VMs communicating over VTGW.
- Native AWS Transit Gateway.

## View Flows over VMware Managed Transit Gateway

You can view the list of all flows that are going over the VTGW, which enables you to view the traffic and helps you to analyze and understand the utilization level of VTGW.

To see all the flows via VTGW, you can run the following query:

```
flows where tgw = ''
```

You can see the flows from SDDC to SDDC, SDDC to VPC, and VPC to SDDC via VTGW using the following flow types:

- SDDC-SDDC via TGW
- SDDC-VPC via TGW
- VPC-SDDC via TGW

> **Note:**
> Flows are not supported between VMC SDDC and on-premise datacenters via VTGW and Direct Connect Gateway.

### VTGW Search Queries

You can search on VTGW entities in VCF Operations for networks.

**Table 1342: Search Queries**

| Description | Query |
|---|---|
| Get a list of flows over VTGW | `flows where tgw = '<tgw-name>'` |
| Get a list of flows between VMC SDDCs over VTGW | `flows where tgw = '<tgw-name>' and flow type = 'SDDC-SDDC via TGW'` |
| Get a list of flows from VMC SDDC to Native AWS VPC over VTGW | `flows where tgw = '<tgw-name>' and flow type = 'SDDC-VPC via TGW'` |
| Get a list of flows from Native AWS VPC to VMC SDDC over VTGW | `flows where tgw = '<tgw-name>' and flow type = 'VPC-SDDC via TGW'` |

| Description | Query |
|---|---|
| Get a list of max egress traffic volume between SDDCs over VTGW | `max(series(sum(bytes))) of flows where tgw = '<tgw-name>' and flow type = 'SDDC-SDDC via TGW' group by Source VMC SDDC` |
| Get a list of max egress traffic volume between VMC SDDC and AWS VPC over VTGW | `max(series(sum(bytes))) of flows where tgw = '<tgw-name>' and flow type = 'SDDC-VPC via TGW' group by Source VMC SDDC` |
| Get a list of max ingress traffic volume between VMC SDDC and AWS VPC over VTGW | `max(series(sum(bytes))) of flows where tgw = '<tgw-name>' and flow type = 'VPC-SDDC via TGW' group by Destination VMC SDDC` |

## Viewing VMC SDDC Group details

You can use the VMC SDDC group page to get an overview of your VMC on AWS SDDC group.

### How to access the VMC SDDC Group page?

To access this page, search for `VMC SDDC Group` and in the search result list, select an entity you want to view.

### Overview

In the **VMC SDDC Group** page, you see:

| Section | Details |
|---|---|
| **Overview** | You see an overview of your VMC SDDC group entities and the counts of VMware Managed Transit Gateway, Direct Connect Gateway, Direct Connect Interface, and so on present within the VMC SDDC group.<br>The **VTGW Route Table** shows the VMware Managed Transit Gateway route details of the entities in that VMC SDDC group. |
| **Flows** | You see an overview of the bandwidth and the traffic usage over the VMware Managed Transit Gateway. |
| **Network Traffic and alerts** | You see an overview of the network traffic and the list of all alerts associated with the VMC SDDC group entities discovered by VCF Operations for networks alerts. |

## Viewing VMware Transit Gateway Details

You can use the VMware Transit Gateway page to get an overview of the VMware Managed Transit Gateway entities.

### How to access the VMware Transit Gateway page?

To access this page, search for `VMware Transit Gateway` and in the search result list, select an entity you want to view.

### Overview

In the **VMware Transit Gateway** page, you see:

| Section | Details |
|---|---|
| **Overview** | You see an overview of the selected entity, with its configuration and runtime property details.<br>The **VTGW Route Table** shows the route details of the selected entity. |
| **Flows** | You see an overview of the bandwidth and the network traffic usage over the VMware Managed Transit Gateway. |
| **Alerts** | You see an overview of the list of all alerts associated with the VMware Managed Transit Gateway entities discovered by VCF Operations for networks alerts. |

## Direct Connect Support in VCF Operations for networks

Direct Connect is a mechanism to provide data transfer connection between an on-premise location and public cloud services. VCF Operations for networks supports the Direct Connect feature for VMware Cloud on AWS.

Direct Connect support enables you to:

- Identify flows that pass over Direct Connect between on-premise data center and VMware Cloud on AWS SDDC.
- Run the flow analytics to understand the flow bandwidth and the packet rate.
- View the detailed path topology between virtual machines that communicate over Direct Connect.
- View details about Direct Connect and associated alerts.

### Direct Connect data fetch mechanism

VCF Operations for networks fetches Direct Connect information by using the VMware Cloud on AWS NSX APIs. Therefore, to get the Direct Connect information, you must add the VMware Cloud on AWS related data sources (VMware vCenter and NSX Manager).

> **Note:**
> You do not have to add an AWS account for Direct Connect support. However, you must add the following Data Sources:
>
> - VMware Cloud on AWS vCenter
> - VMware Cloud on AWS NSX Manager
> - On-premise VMware vCenter
> - On-premise NSX or On-premise NSX Manager
> - On-premise DC Perimeter Physical Router (Supported routers include Cisco N9k and Cisco ASR 9k)
> - DX Colo Physical Router (Supported routers include Cisco N9k and Cisco ASR 9k)
>
> These data sources are required by VCF Operations for networks to construct VM-VM path topology and to enrich the IPFIX flows with Direct Connect information.

### What data is collected with Direct Connect support

- Direct Connect related configuration details in the VMware Cloud on AWS SDDC.
- Advertised and learnt subnets for Direct Connect at the SDDC level.
- Configuration information of Direct Connect Interfaces (VIFs) associated with the SDDC.
- Flows reported by Distributed Firewall (DFW) in VMware Cloud on AWS.

> **Note:**
>
> - The NetFlow enablement is not required on the colocation routers.

- Route based VPN is not supported for Direct Connect. So, even if you have enabled the Use VPN as backup to Direct Connect option, VPN backup fails.
- The metrics, and the advertised or learnt subnets information is not available at the individual VIF level.

**Direct Connect Entities**

- *VMware Cloud on AWS Direct Connect:* This is the parent entity for all Direct Connect entities in VCF Operations for networks, which models the configuration information of Direct Connect within the VMware Cloud on AWS SDDC.
- *Direct Connect Interface*: This models the AWS Direct Connect VIF information provided by VMware Cloud on AWS. This entity enables the exchange of advertised and learnt routes between VMware Cloud on AWS and on-premise data center.

## Viewing VMC Direct Connect Details

You can see the **VMC Direct Connect** page for an overview of its properties and the entities associated with Direct Connect based on the information collected from VMware Cloud on AWS.

**Table 1343: Direct Connect Dashboard**

| Section | Details |
|---|---|
| Properties | Primary properties of Direct Connect, which includes the associated SDDC, local ASN, learned and the advertised routes, failed advertised routes. |
| Direct Connect Interfaces | The list of all Direct Connect Virtual Interfaces that are associated with the Direct Connect |
| Network Traffic and Alerts | The network traffic statistics for Direct Connect connections. You get detailed information about total data volume, packet count and bandwidth between datacenters over Direct Connect.<br>The list of alerts associated with Direct Connect. |
| Top Talkers | You can see the top talking entities in VMC SDDC that are communicating over Direct Connect. |

## Viewing Flows over Direct Connect

You can view the list of all flows that are running on the Direct Connect, which enables to view the traffic over Direct Connect. This helps you to analyze and understand the utilization level of Direct Connect.

When you search with the `Flows where connection = Direct Connection_ID` query, you see the list of flows that pass over the Direct Connect, and also information such as the bandwidth utilization, and network traffic rate for a particular Direct Connect. Update this line - Under the Flow Type, you can see whether the flow is on VPN, Direct Connect, or on the hybrid network.

To see the Direct Connect flows only, you can run the following query:

```
flows where flow type = Direct Connect group by Connection
```

To see the count of flows and the data volume on each Direct Connect connection, run the following query:

```
max(series(sum(Bytes)))of Flows where flow type = Direct Connect and group by Connection
```

To see the count of flows and the packet count on each Direct Connect Interface, run the following query:

```
max(series(sum(packets)))of Flows where flow type = Direct Connect and group by Connection
```

For additional queries, see Direct Connect Search Queries.

## Direct Connect Search Queries

You can search on VMware Cloud on AWS Direct Connect and Direct Connect Interface entities in VCF Operations for networks.

**Table 1344: Search Queries**

| Description | Query |
|---|---|
| Get a list of VMware Cloud on AWS Direct Connect entities based on which you can filter the information | `VMC Direct Connect where` |
| Get the VMware Cloud on AWS Direct Connect list view | `VMC Direct Connect` |
| Get the maximum data volume over Direct Connect | `max(series(sum(bytes))) of flows where connection = 'Connection-ID' and flow type ='Different Dc' and source vm is set and destination vm is set and flow type = 'Direct Connect'` |
| Get the maximum packets over Direct Connect | `max(series(sum(packets))) of flows where connection = 'Connection-ID' and flow type ='Different Dc' and source vm is set and destination vm is set and flow type = 'Direct Connect'` |
| Get the maximum packets over Direct Connect to the Internet | `max(series(sum(packets))) of flows where connection = 'Connection-ID' and flow type ='Destination is internet' and flow type = 'Direct Connect'` |
| Get the maximum data volume over Direct Connect to the Internet | `max(series(sum(bytes))) of flows where connection = 'Connection-ID' and flow type = 'Destination is internet' and flow type = 'Direct Connect'` |
| Get the maximum packets between data centers over Direct Connect | `max(series(sum(packets))) of flows where connection = 'Connection-ID' and flow type ='Different Dc' and source vm is set and destination vm is set group by Source Dc, Destination Dc and flow type = 'Direct Connect'` |
| Get the maximum data volumes between data centers over Direct Connect | `max(series(sum(bytes))) of flows where connection = '64638-10.63.229.131' and flow type ='Different Dc' and source vm is set and destination vm is set group by Source Dc, Destination Dc and flow type = 'Direct Connect'` |

# VCF Operations for networks General FAQs

The VCF Operations for networks FAQs guide provides the user with frequently asked questions about VCF Operations for networks.

### Intended Audience

This information is intended for users who work with VCF Operations for networks.

### How do I Create a Support Bundle?

Refer to the Broadcom knowledge base article 343485.

### How to Create a read-only Admin Role in Palo Alto Networks Panorama for XML API access?

To add an **Admin** role for XML API access:

1. Select **Panorama** > **Admin Roles**.
2. Click **Add** to add a new Admin Role to open Admin Role Profile dialog box
3. In Admin Role Profile dialog box
   a. Give a name to the role (for example, `api-only-admin`)
   b. Select the **Role** as **Panorama**
   c. Deactivate all entries in the Web UI tab
   d. Enable all entries except **Commit** in the XML API tab
   e. Click **OK** to close the dialog box, a new **Admin Role** appears in the list with the name
   f. Click **Commit** to commit the changes to Panorama
4. Assign this **Admin** role to an administrative account.

### I see an event/error on Data Source as "The data source identity information such as a certificate or the key has changed." What does it mean?

VCF Operations for networks has received a new certificate from a data source which is not the same as the one stored in the product. You can accept the new certificate by navigating to the data sources page and accepting the new certificate for that data source.

### What is the limit for importing DNS records in VCF Operations for networks?

The limits for importing DNS records are:

- Infobox DNS Data source: You can import 900K records from a single data source.
- Manual DNS records import: You can import DNS records using multiple `.csv` or Bind files packaged as a zip file. There is no limit to the number of records that you can import, however there are upload limits as follows:
  – Number of files in a single zip file – 25
  – Max size of single zip file – 10 MB.

## Installation and Configuration

### What are the resource requirements for VCF Operations for networks?

Refer to the VCF Operations for Networks System Recommendations and Requirements topic for Resource Requirements.

### What happens if I enter the incorrect key during VCF Operations for networks collector OVA deployment?

The secret key is not validated during VCF Operations for networks collector OVA deployment. The deployment completes even with an incorrect secret key. However, pairing can fail and VCF Operations for networks collector does not show up as detected on VCF Operations for networks UI.

To correct the shared secret, log in to VCF Operations for networks collector CLI and run the `set-proxy-shared-secret` command to set the correct secret key. This command replaces the old key with the new one, and therefore, VCF Operations for networks platform detects the VCF Operations for networks collector and pairs up.

### How do I configure DNS after VCF Operations for networks collector OVA is deployed?

Log in to VCF Operations for networks collector CLI, and run the change-network-settings command. This interactive command will provide the user an option to add or modify DNS after which the VCF Operations for networks collector will be reconfigured with the new DNS.

If any of the network parameters is not configured correctly, use the change-network-settings command to modify the network configuration parameters.

**How do I find out VCF Operations for networks collector VM IP from the UI?**

Go to Settings page and select VCF Operations for networks Infrastructure menu option. The IP address of both, VCF Operations for networks Platform and VCF Operations for networks collector VMs is displayed.

**What should I do if VCF Operations for networks collector is not detected in 5 minutes after deploying VCF Operations for networks collector OVA?**

Log in to VCF Operations for networks collector using `consoleuser` (refer to the VCF Operations for networks Command-Line Interface Guide) and verify the following:

- Verify VCF Operations for networks platform pairing status with VCF Operations for networks collector using the CLI `show-connectivity-status` .
- If the pairing stating is shown `Passed`, open the platform UI in a new browser window and login to check status.
- If the pairing status is showing `Failed`, then the shared secret key specified during the VCF Operations for networks collector OVA deployment could be wrong. To fix this problem, use the `set-proxy-shared-secret` command to set the correct secret key. This command replaces the old key with the new one, and therefore, VCF Operations for networks platform can detect VCF Operations for networks collector.
- If the `show-connectivity-status` shows network reachability to VCF Operations for networks Platform as **Failed**, then verify whether VCF Operations for networks platform is reachable from VCF Operations for networks collector VM using the `ping` command.
- If it is not reachable, then verify if NTP, DNS, gateway, and other network parameters are configured correctly using `show-config` command.
- If any of the network parameters is not configured correctly, use the `setup` command to modify the network configuration parameters.

**What should I do if I forget my login credentials?**

- If you are the UI local user: Contact VCF Operations for networks UI administrator to reset the credentials for you.
- If you are the administrator: Reset the VCF Operations for networks UI credentials using CLI `modify-password`.
- If you are working on VCF Operations for networks versions prior to 9.0, contact support.

**How do I change the login password?**

To change the login password:

1. On the VCF Operations for networks standalone UI, go to **Settings** > **My Preferences** > **Change Password**.
2. On the **Change Password** page, fill in the required information and click **Save**.

**What do I do if I get the login screen before detecting the VCF Operations for networks collector VM?**

- This behavior is expected when the browser is refreshed or URL is opened in a new window before detecting the collector.
- Log in by using the credentials set during license activation for the `admin@local` username.

**Does VCF Operations for networks support multiple vCenter/NSX instances?**

Yes, VCF Operations for networks supports multiple vCenter and NSX Manager.

**What is port aggregation and what is the mechanism to do it?**

Port aggregation is built in to aggregate the ephemeral port flows – like dynamic FTP, Oracle, MS-RPC etc. This helps in reducing the number of flows in system and provide an aggregated view for large number of flows that are essentially for the same service.

The mechanism to do it is as follows:

- For first three days of noticing a `destination_ip`, we will aggregate destination ports on that particular IP in buckets of 10K and start building a port-profile for that IP (build a port-profile per destination IP).

- After three days, once we have built a profile, we will start aggregating port ranges where the port density is high (reflect ephemeral port opening pattern). The ranges themselves will be dynamic in size such as 100, 1,000, 10,000, and will be created depending on how many ports are being opened and how widespread they are in the given range of aggregation.

  **Note:**
  This decision happens independently for each server IP address.
- This will enable high-port flows to be reported with no aggregation where there is no bulk port open activity happening and also let dynamic aggregation to be applied where such activity is happening.
- The profile is continually updated in a time-decayed manner to account for new ports opening up or older ones being not used any more.

**How do I change the IP Address, Gateway, or Netmask after VCF Operations for networks OVA is deployed?**

To change VCF Operations for networks platform/collector network settings, log in to CLI and run the `change-network-settings` command. This interactive command will provide the user an option to modify the IP address, gateway, netmask, and so forth after which the VCF Operations for networks appliance is reconfigured with new details.

**Note:**

- This task must be done using VM console session as the appliance reboots in the end.
- If VCF Operations for networks Platform IP is modified and it is paired with proxies then on each collector VM run this CLI command:

  ```
  pair-collector set-platform --ip-or-fqdn <New_Platform_IP>
  ```
- For more information on changing IP address of any collector or platform node using the CLI commands, see How to change the IP of any platform node or a collector in a cluster?

**How do I change from an Evaluation License to a VCF License?**

Refer to the Add and Change License section in the VCF Operations for networks User Guide.

## Adding a vCenter Account

**What if I am getting a "Request timed out" message while adding vCenter using IP address?**

- Verify that the vCenter Server IP address is reachable from the VCF Operations for networks collector VM.
- Log in to VCF Operations for networks collector CLI and use the ping to ensure that IP is reachable and telnet to ensure that the vCenter is reachable on port 443.
- If vCenter is reachable, then retry adding.
- If IP address is not reachable, then verify whether the gateway is correctly configured from VCF Operations for networks collector VM using command `show-config`.
- If gateway is incorrect, then correct it using the `setup` command by logging in to CL with `consoleuser`.

**What if I am getting a "IP/FQDN is invalid" message while adding vCenter ?**

- Verify whether provided IP/FQDN for vCenter is correct.
- Verify whether FQDN is reachable from VCF Operations for networks collector VM using `ping` command.
- If it is not reachable, then verify if the DNS is configured correctly on VCF Operations for networks collector VM using `nslookup FQDN` and `show-config` command.
- If DNS is incorrect, then correct it using the `setup` command by logging in to CL with `consoleuser`.

**What privileges are required to add a vCenter instance in VCF Operations for networks?**

VCF Operations for networks requires the VMware vCenter credentials with the following privileges:

- System.Anonymous
- System.Read
- Global.Settings

- System.View

**What VC privileges are required to resolve the 'User does not have required privileges.' error when enabling Netflow/IPFIX on the source page?**

VCF Operations for networks requires the vCenter credentials with the following privileges to enable Netflow/IPFIX:

- Distributed Switch: Modify
- dvPort group: Modify

Please make sure that provided vCenter user have permission on vCenter root folder and all of its child entities e.g all folders and all datacenters.

**How frequently is the data fetched from the environment?**

VCF Operations for networks collector fetches data every 10 minutes from vCenter, NSX, AVI (NSX ALB), and HCX.

**How soon the analysis of data will start after adding the vCenter instance?**

Analysis of data starts right away after adding a vCenter instance. Product UI will show partial picture of data within few minutes which can take two hours to get complete.

> **Note:**
> Flow traffic data changes continuously and include at least 24 hours of data in its analysis.

**How do I clean up Netflow/IPFIX settings in vCenter if I have deleted the VCF Operations for networks appliance?**

- Using VMware vSphere Web Client: Go to **Home** > **Networking** > **VDS (Name)** > **Netflow** Settings. Remove VCF Operations for networks collector IP from Collector settings.
- Using VMware vSphere Windows Client: Go to **Home > Inventory > Networking > VDS (Name) > Edit** Settings. Remove VCF Operations for networks collector IP from Collector settings in Netflow tab. This step is required to be done for each VDS for which Netflow/ IPFIX is enabled.

**How do I clean up Netflow/IPFIX configuration in VCF Operations for networks?**

In VCF Operations for networks standalone UI, go to **Settings** > **Accounts and DataSources**, and select the target vCenter. Click the vertical ellipsis and click **Edit**. Navigate to the additional information section and uncheck **Netflow/ IPFIX**T. Click **Submit** to submit the data source and save the changes. This removes Netflow/ IPFIX configuration that is done by VCF Operations for networks.

**How much time does it take to show correct firewall rules in the VM-VM path after adding VMware NSX in VCF Operations for networks?**

After you add VMware NSX Manager in VCF Operations for networks, it can take up to 26 hours to compute the VM to the firewall rule relationship.

**Why I am unable to see the PNIC in the VM-VM path after adding vCenter in VCF Operations for networks?**

Normally, it takes around two hours for VCF Operations for networks to compute the VM-VM path after you add a vCenter instance in VCF Operations for networks as a data source. But in some rare situations, it can take around 8-10 hours to show the PNIC correctly in the VM-VM path after you add the VMware vCenter in VCF Operations for networks.

## Micro-Segmentation and Network Traffic Flows

**What do the numbers in the Traffic Distribution Pin represent?**

The percentage gives an overview of the traffic distribution based on flow analysis.

**Table 1345:**

| Traffic | Description |
|---|---|
| East-West (EW) | East-West traffic as the percentage of the traffic of the total group |
| Switched (% of EW) | Switched traffic as the percentage of East-West traffic |
| Routed (% of EW) | Routed traffic as the percentage (%) of East-West traffic |
| Within Host (% of VM-VM) | Traffic with source and destination on same host as percentage of virtual machine to virtual machine traffic |
| VM to VM (% of EW) | Virtual machine to virtual machine traffic as percentage of East-West traffic |
| Internet | Internet traffic as percentage of the traffic of the total group |

**How are ports aggregated in flows?**

Port aggregation is built in to aggregate the ephemeral port flows - like dynamic FTP, Oracle, MS-RPC etc. This helps in reducing the number of flows in system and provide an aggregated view for large number of flows that are essentially for the same service. The mechanism to do this is as follows:

- For first three days of noticing a destination_ip , we aggregate dst ports on that IP in buckets of 10K and start building a port-profile for that IP.
- Once three days are over - and we have built a profile that can be used with confidence - we will start aggregating port ranges where the port density is high (in other words - reflect ephemeral port opening pattern). The ranges themselves will be dynamic in size - 100, 1,000, 10,000 and will be created depend on how many ports are being opened and how widespread they are in the given range of aggregation.
- This will enable high-port flows to be reported with no aggregation where there is no bulk port open activity happening; and also let dynamic aggregation to be applied where such activity is happening.
- The profile is continually updated in a time-decayed manner to account for new ports opening up or older ones being not used any more.

**What does the 240.240.240.240 IP address signify in VCF Operations for networks?**

240.240.240.240 is a place holder IP address in VCF Operations for networks. This IP address is used if there are very large number of IP addresses (> 5000) hitting some particular IP. All further incoming Internet IPs (5001th onwards) with this placeholder IP 240.240.240.240 can be replaced for that service end point.

This is to limit the number of flows in the system, as publicly exposed service that log each internet client individually could result in very large number of flows - which would result in increased system load.

For all the flows that have been replaced with this placeholder IP, all the metrics are aggregated on the corresponding flow with this IP address, so there is no loss of statistics at an aggregate level.

All the destination IP for the flows reported in the flows view are shown as originating from 240.240.240.240 are actually being hit by large count of internet IP ( > 5000).

**Which are the protocols supported while configuring flows in VCF Operations for networks?**

The TCP and UDP protocols are supported while configuring flows in VCF Operations for networks.

**Does VCF Operations for networks handle de-duplication and aggregation of flow attributes from multiple sources?**

Yes, in VCF Operations for networks, the same data reported from multiple sources is de-duplicated and the best metric among all the sources is considered. Also, different attributes from multiple sources are aggregated and shown on the flow.

> **Note:**
> The Reporter field in the flow shows the reporter of the flow.

#### Why can't we see the VM names in the source or destination of the flows?

Some of the reasons for a VM (Source, Destination) not being attached to a flow are:

- The source or the destination vCenter data source is not added
- The IP is physical IP or Internet IP or Kubernetes POD or Container IP
- If the vmtools is not installed or active on the VM and the flow is not reported from the VDS
- If there are multiple nics assigned with the same IP and there is no NATing involved

#### Why do we see multiple Firewall rules on a flow?

When a firewall rule is changes from R1 to R2, VCF Operations for networks shows the new firewall rule (R2) but does not immediately remove the old firewall rule (R1). It takes up to six hours for the old rule to be removed. During this time period, before the old rule is removed, both the rules are displayed. If this happens multiple times (for example, R1 is changed to R2 and then R2 is changed to R3 before the old rule is removed), you will see multiple firewall rules for a single flow.

#### What is the flow count for a data source page and how is it calculated?

The numbers shown on the data source page are the unique flow counts (four tuples) seen from the data source in last 24 hours and the value is updated regularly (every 5 minutes). The flow count number might change, as it only considers the flows of last 24 hours. The count must match the result for the query: `'count of flows where reporter = '`.

## Data Management and Processing

#### What is the default retention period?

The default retention period is one month. Retention can be configured for non-flow data (configuration, event, and metric data) beyond one month from **Settings** > **Data Management**. Flow data retention is fixed at one month and cannot be changed.

#### How data is handled on the collector?

All data on the collector, including flow data is converted to SDM (Self Describing Message) before being sent to the platform. This includes all configuration, inventory, and metric data from any data source. If the platform is unreachable, or sending the data fails, it is written to disk on the collector VM (under **/var/BLOB_STORE**) until it can be sent.

#### When will data start to purge on the collector?

For processed data: 20 GB of disk space is allocated to store data on disk, split equally between inventory and metric data. When this space fills up, the oldest data is deleted to make room for new data. For raw flow data: Disk space is allocated to store raw flow data — 15 GB for single-collector deployments, or up to 45 GB in deployments using secondary collectors. As this space fills, older flow files are deleted to make room for new ones.

#### How is data deleted when the allocated limit is breached?

Both processed data and raw flow records are deleted in the order that they were received — the oldest data is always deleted first.

#### When will new data stop being processed on the collector?

Inventory and metric data are always processed as long as collector services are healthy. Flow data processing may pause if the active flow limit is reached — either on the specific collector or across the platform overall.

#### If the connection between platform and collector is lost, and no data has been purged, will all data reconcile once reconnected?

Yes, all data stored on disk on the collector is sent to the platform once connectivity is restored, and should reconcile completely — except where data loss conditions exist on the platform side (see below).

#### What conditions can cause data loss on the platform?

Flow data may stop being sent to the platform if the platform-wide active flow limit is reached. Metric data, including flow metrics, may be dropped if there is a processing lag of more than 8 hours on the platform.

#### In what order is data sent when the connection is re-established?

The oldest data is always sent first.

#### Is data stored on disk on the collector even when there is no connectivity problem?

If there is no communication issue, data is sent directly to the platform without being written to disk. Data is only written to disk after a failed attempt to send it.

#### How does the collector know which flow data was already processed if there is an interruption?

The collector tracks the last flow data that it successfully processed, so it can resume from where it left off after any interruption.

#### What is the maximum size of a single data message, and how would I know if one is dropped?

There is a 15 MB limit on the size of a single data message. If the platform drops a message for exceeding this limit, an alert is raised so you are aware of it.

## IPFIX

#### What is IPFIX?

IPFIX is an IETF protocol for exporting flow information. A flow is defined as a set of packets transmitted in a specific timeslot, and sharing 5-tuple values - source IP address, source port, destination IP address, destination port, and protocol. The flow information may include properties such as timestamps, packets/bytes count, Input/output interfaces, TCP Flags, VXLAN ID, Encapsulated flow information and so on. This is often referred to as Netflow. However, IPFIX is the standard IETF protocol.

#### What flow information is exported by the VDS?

A VDS in vSphere environment can be configured to export flow information using IPFIX. Enable flow monitoring on all the port groups attached to the VDS. If packets arrive on port X of a VDS and exit from port Y, a corresponding flow record is emitted if flow monitoring is enabled on port Y. The direction of every flow record is set as "Egress".

#### How does VCF Operations for networks use IPFIX?

VCF Operations for networks uses VMware VDS IPFIX to collect network traffic data. Every session has two paths. For example: Session A↔C has A→C packets and C→A packets. To analyze the complete information of any session, IPFIX data about packets in both the directions is required. Refer following diagram where VM-A is connected to DVPG-A and is talking to VM-C. Here DVPG-A will only provide data about the C→A packets, and DVPG-Uplink will provide data about A→C packets. To get the complete information of A's traffic, IPFIX should be enabled on DVPG-A, DVPG-uplink.

#### How do I troubleshoot VCF Operations for networks Flow Collection?

1. Please ensure that the specific VDS and its DVPGs and Uplink properties has Netflow monitoring **Enabled** and the collector IP address is that of VCF Operations for networks collector.
2. IPFIX Netflow packets are getting dropped in between by a firewall (NSX, Virtual or Physical). Please ensure that the Netflow packets destined for UDP port 2055 on VCF Operations for networks collector IP is allowed by any firewall that may be present in the route between ESXi Host and the VCF Operations for networks Collector.
3. The ESXi host has ceased to send IPFIX Netflow packets. The ESXi host backs off sending the Netflow packets after some time if UDP port 2055 is not reachable. This may happen due to the firewall dropping the packets.

4. The VCF Operations for networks collector is not reachable by ESXi Host due to network routing problem. Ensure that the proper routroute existse exist between ESXi Host and the VCF Operations for networks collector.

**When is a service considered shared?**

| Protocol | Port |
|---|---|
| DNS | 53 |
| Bootpc | 68 |
| Kerberos | 88 |
| Pop3 | 110 |
| sunrpc | 111 |
| NTP | 123 |
| map | 143 |
| Imap3 | 220 |
| SMTP | 25 |
| LDAP | 389 |
| IGMPv3Lite | 465 |
| syslog | 514 |
| Submission | 587 |
| syslog-conn | 601 |
| LDAPS | 636 |
| IMAPS | 993 |
| POP3S | 995 |
| NFS | 2049 |
| MSFT-GC | 3268 |
| MSFT-GC-SSL | 3269 |

## Clustering - General

**Can a collector VM be clustered?**

No. Clustering of collector VMs is not supported.

**Does VCF Operations for networks need a load balancer like VCF Operations for logs?**

VCF Operations for networks clustering functions as a scale-out mechanism rather than a high availability solution; a failure of the primary node causes the entire service to become unavailable.

**What happens if the connection between remote collector & platform goes down?**

In case the connection between platform and collector VM is down, the collector VM stores data locally (depending on the disk space) and sends it whenever it is connected again.

**Can VCF Operations for logs be integrated with VCF Operations for networks?**

Yes, VCF VCF Operations for logs can be integrated with VCF Operations for networks for direct log collection using the VCF Operations UI.

### What happens when a node reboots?

If a collector node reboots, there is data loss during the downtime. For more information, see the Broadcom Knowledge Base article 314428.

### How to change the IP of any platform node or a collector in a cluster?

In a cluster, you can change the IP of any collector or platform node using the CLI commands.

For more information on updating network settings and IP addresses, see the following Broadcom Knowledge Base articles:

- For Standard/Standalone Deployments: 370647
- For Clustered Deployments & Multi-Node Platform Migrations: 423336

  **Note:**
  The appliance reboots at the end of the process. So you must perform these steps on the VM console.

- To change the collector IP, run the `change-network-settings` command.
- To change the platform IP,
  a. Run the `change-network-settings` command to change the IP.

     **Note:**
     Ensure that the platform VM reboots successfully before you run the next command.
  b. For every platform whose IP is changed, run `update-IP-change` command on all the other nodes.
     For example, for the IP change of platform1 from IP1 to IP2, run the `update-IP-change` command on platform2 and platform3 with IP1 and IP2 as the arguments. For the IP change of platform2, run the `update-IP-change` command on platform1 and platform3.
  c. Run `finalize-IP-change` command on platform1 after step1 and step 2 are completed.
  d. Run the `show-connectivity-status` command on a collector and search for `Platform VM IP/URL` to identify if it is associated to this platform.

e. Run `pair-collector` to reflect new platform IP on associated collectors.

| Scenarios | Procedure |
|---|---|
| In a 3-Node cluster, only the platform2 IP is changed. No collector shows associated with it. | 1. Run the `change-network-settings` to change the IP on platform2.<br>**Note:**<br>Ensure that the platform VM reboots successfully before you run the next command.<br>2. Run `update-IP-change` command on all the other nodes, except platform2.<br>For example, for the IP change of platform2, run the `update-IP-change` command on platform1 and platform3.<br>3. Run `finalize-IP-change` command on platform1 after step1 and step 2 are completed. |
| In a 3-Node cluster, platform1 and platform2 IPs are changed. | 1. Run `change-network-settings` on platform1.<br>2. Run `change-network-settings` on platform2.<br>**Note:**<br>Ensure that the platform VM reboots successfully before you run the next command.<br>3. Run `update-IP-change platform1-oldIP platform1-newIP` on platform2 and platform3.<br>4. Run `update-IP-change platform2-oldIP platform2-newIP` on platform1 and platform3.<br>5. Run `finalize-IP-change` command on platform1.<br>6. Run the `show-connectivity-status` command on all the collectors and search for `Platform VM IP/URL` to identify the associated platform nodes.<br>7. Run `pair-collector set-platform --ip-or-fqdn platform-newIP` on collectors that are associated with platfrom1 and platform2.<br>For example, if the CollectorA is associated to platform2, rest are associated to platform3, run `pair-collector set-platform --ip-or-fqdn platform2-newIP`.<br>8. Run `pair-collector set-platform --ip-or-fqdn platform-newIP` on collectors that are associated with platfrom1 and platform2.<br>For example, if the CollectorA is associated to platform2, rest are associated to platform3, run `pair-collector set-platform --ip-or-fqdn platform2-newIP`. |

| Scenarios | Procedure |
| --- | --- |
| In a multi-node cluster setup, all the platform and collector IP are changed. | 1. Run `change-network-settings` command on all platforms to change the IP.<br>**Note:**<br>Ensure that the platform VM reboots successfully before you run the next command.<br>2. Run `update-IP-change` command on all the nodes.<br>For example, in a 3-node cluster, to update IP of platform1 from IP1 to IP2, run the `update-IP-change` command on platform2 and platform3 with IP1 and IP2 as the arguments. To update IP of platform2, run the `update-IP-change` command on platform1 and platform3.<br>3. Run `finalize-IP-change` command on platform1.<br>4. To change the collector IP, run the `change-network-settings` command.<br>5. Run the `show-connectivity-status` command on all the collectors and search for `Platform_VM_IP/URL` to identify the associated platform nodes.<br>6. Run `pair-collector set-platform --ip-or-fqdn platform-newIP` on all collectors.<br>For example, if the CollectorA is associated to platform2, run `pair-collector set-platform --ip-or-fqdn platform2-newIP`. |

**How much disk space is needed on platform1?**

Platform1 requires more disk space compared to other nodes in the cluster as some of the configuration data is stored on Platform1 only.

**What happens if any of the nodes ran out of disk space?**

The UI starts showing error messages when disk space on any particular platform node reaches a certain threshold. Add more disk space to the platform node by logging in to VMware vCenter. The platform/collector VM must be in powered-on state while adding disk space. For more information, see Increase the Disk Size.

**What is the replication factor of data in the platform cluster?**

The replication factor is 2 for all persisted data in the platform cluster. There is no replication on the collector side.

**How to change the hostname of a platform or a collector node?**

You can update the hostname of a platform or a collector VM using the `hostname update` command. Updating the hostname helps you easily identify the collector VM or the platform VM in your data center and align the naming convention of the VM with other VMs in your data center.

To change the hostname of platform VMs or collector VMs, perform these steps:

1. Log in to the respective VM console.
2. Switch to a Ubuntu user.
3. Run the `hostname show` command to view the present hostname of VCF Operations for networks collector or platform VMs.
   ```
   hostname show
   ```
4. To view the supported options, run the following command:
   ```
   hostname update --help
   ```

**Note:**

You use the `hostname update` command to update the hostname.

| Option | Description |
|---|---|
| --dryrun | This option validates the new hostname without updating the hostname in VCF Operations for networks. |
| --hosts | This option updates the hostname of your VMs in VCF Operations for networks. |

5. Run the `hostname update --dryrun` command to validate the new hostname.
   Syntax:
   - To validate the hostname of a platform or a collector VM in a single node VCF Operations for networks instance, run the following command:
     `hostname update --dryrun --hosts <new_hostname>`
   - To validate hostnames of platform VMs in a cluster, run the following command:
     `hostname update --dryrun --hosts platform1:<new_hostname1> platform2:<new_hostname2> platform3:<new_hostname3>`

     **Note:**

     - Use the following guidelines for hostnames:
       - Use only alphanumeric characters, period ("."), and hyphens("-") in the hostname.
       - Use less than 64 characters.
       - Do not start or end the hostname with a period or a hyphen.
6. Run the `hostname update --hosts` command to update the hostname.
   Syntax:
   To update the hostname of a platform or a collector VM in a single node VCF Operations for networks instance, run:
   `hostname update --hosts <new_hostname>`
   To update the hostname of one or more platform VMs in a cluster, run the following command:
   `hostname update --hosts platform1:<new_hostname1> platform2:<new_hostname2> platform3:<new_hostname3>`

   **Note:**

   After changing the hostname, it takes up to an hour for the hostname to reflect on the VCF Operations for networks UI.

## Clustering - Installing and Configuring

### Do all platform VMs have to be on the same L2/L3 segment?

No. However, it is best to keep all platform nodes on a common network with low latencies between nodes. This is because many of the distributed components replicate data among the nodes and high latencies can cause system performance and stability issues. For more information, see VCF Operations for Networks System Recommendations and Requirements.

### What happens if there is a failure during the cluster creation process?

- Cluster creation for single node: Before converting a single node to a multi-node cluster, take a cold snapshot of the original platform, the new platform, and all deployed collectors. If a failure occurs, delete the secondary platform nodes and recover the primary platform and collector virtual machines from the snapshot.

**What happens if there is a failure during the cluster expansion process?**

Similar to the cluster creation scenario, take snapshots of the existing cluster and the newly deployed nodes (all platform nodes and collectors) and perform the steps mention in the following Broadcom Knowledge Base article KB article 314428.

**What happens to the existing data and configuration when I expand the single node deployment to a cluster?**

All data and configuration is maintained without any change. The data will be accessible after cluster creation.

**Can you have platform VM in different regions?**

No, we require the Platform nodes to co-located be in the same site. The collector servers can be geo-distributed.

The collector communicates with vCenter over HTTPS to pull inventory, configuration, VM topology, and push that data to the platform. You only need one collector for each vCenter instance. Collectors do not need to be assigned for each ESXi host or cluster—even if that vCenter manages hundreds of remote sites.

IPFIX data is exported toward the collector over UDP port. Every exporter (ESXi host) must have a working network path to the collector. If hosts are in remote sites with high latency or bandwidth constraints, sending flows across WAN links to a central collector can be inefficient.

**Can platform hosted on vSAN Stretch clusters (2 Data centers)?**

Yes, vSAN clusters within the same or across data centers would still ensure certain IO performance like local storage. For more information, see VCF Operations for Networks System Recommendations and Requirements.

**Can we host cluster nodes on different vSAN Clusters?**

Yes, Different nodes of a Platform cluster could be hosted on different underlying datastores.

## Clustering - Scaling

**Can I extend an already created cluster?**

Yes, extending a cluster is supported up to 15 nodes.

**What happens if a non-primary platform VM becomes unavailable?**

Grid processing halts; however, UI and API access remain available through the primary node. The system retains previously processed and stored data. Extended node unavailability can result in the permanent loss of incoming data. Upon node restoration, the system processes only the most recent data.

**What kind of load balancing is supported?**

External load balancers are not supported. The system internally load balances API calls directed to the platform, whether accessed directly or through the user interface. The collector manages load balancing for collector-to-platform communication, routing traffic to the platform cluster using a round-robin method.

**Will creating a platform cluster increase network bandwidth consumption between collector and platform?**

Collector-to-platform traffic is distributed across the platform cluster. Aggregate bandwidth consumption from the collector remains constant. However, as the cluster forms and processes additional data, bandwidth requirements increase proportionally.

**What is the frequency of data transmission between collector VM to platform VM?**

The collector VM sends data to the platform VM continuously.

**Does any optimization of data take place in the collector VM?**

Various deduplications, compressions, reduction, or batching steps happen in the collector VM. When the connection between the platform VM and the collector VM is down, the collector VM stores data locally (depending on the disk space) and sends it whenever the connection is restored.

**Is there any optimization done for network bandwidth?**

Yes, various deduplication/ compressions/ reduction/ batching steps happen on the collector VM.

**Is clustering possible on the collector?**

No. Clustering is not possible on the collector.

**How does vCenter send traffic to the collector?**

vCenter instances do not send traffic to the collector. The collector connects to configured vCenter instances to fetch inventory and metric data. VDS exports IPFIX NetFlow data to the collector via UDP.

### Clustering - Deployment

**What is Platform1 and why do I need to remember this node?**

The system designates the node that is used to initiate the cluster creation process as Platform1. Perform all external integrations and backend operations exclusively from Platform1. Platform1 also helps to change network across cluster nodes from CLI.

**How do I access the UI after scaling out the cluster?**

The UI can be accessed from any platform node.

**Can I use a platform node which is deployed in different data center for creating clusters?**

Nodes within a cluster exchange data continuously. To prevent latency, a cluster must consist of platform nodes deployed in the same data center.

**What happens to data on existing platform when I scale out the platform node?**

The data on an existing platform node is preserved and distributed across all nodes in a cluster.

**Do the number of collector VMs and data sources, including physical devices, determine the required platform cluster size?**

The size of the platform cluster is determined by the number of VMs, number of flows, number of network rules, and applications, etc. For more information, see VCF Operations for Networks System Recommendations and Requirements.

**Does VCF Operations for networks support platform cluster distributed across 2 data centers for HA reasons?**

No. The platform Cluster does not support splitting across data centers. All Platform Cluster VMs should be in the same site. Platform Cluster does not support HA today.

## Metric Definitions in VCF Operations for networks

To display different types of metrics on the user interface, VCF Operations for networks collects data from multiple data sources. Each piece of data collected is called a metric observation or a metric value.

VCF Operations for networks displays the following metrics on the user interface:

| Metric Type | Description | Data Sources Supporting the Metric |
|---|---|---|
| Entity metrics | Entity metrics display information such as resource utilization and performance of entities in your network. They include metrics such as host metrics, VM metrics, datastore metrics, and so on.<br>To learn more, see Entity Metrics | All data sources added to VCF Operations for networks except ServiceNow, Infoblox, and VCF Operations for logs data sources. |
| Flow metrics | Flow metrics display the traffic flow data collected from flow-enabled data sources on your network.<br>The flow data from the data sources is:<br>• Derived and aggregated to show different flow metrics such as total bytes, traffic rate, and so on.<br>• Aggregated on the tier level to show application tier metrics such as average drop flows, total internet packet, and so on.<br>To learn more, see Flow Metrics. | • VMware vCenter<br>• NSX Manager<br>• Netflow collector<br>• Physical flow collector |
| Health metrics | Health metrics represent the overall health of the VCF Operations for networks instance. These metrics are useful in diagnosing health problems related to the VCF Operations for networks instance.<br>To learn more, see Health Metrics. | VCF Operations for networks Collector and Platform |
| Latency metrics | Latency metrics display information about the latency of data packets traveling between the following devices:<br>• Interface pNIC pairs<br>• Interface pairs<br>These metrics are useful in monitoring the latency of the network to diagnose and troubleshoot performance bottlenecks.<br>To learn more, see Latency Metrics. | NSX-T Manager |
| VM network utilization metrics | The VM network utilization metrics display the performance of the VM based on network utilization. These metrics are critical to track network activity and throughput.<br>In VCF Operations for networks, these metrics are displayed at 20 second resolution to showcase the peaks and troughs of network utilization.<br>**Note:**<br>VM network utilization metrics are displayed at 20 seconds granularity only if you are viewing the metric chart within the last 48 hours.<br>Beyond 48 hours, the metric resolution is displayed based on the selected time range.<br>See VM Network Utilization Metrics to learn more. | VMware vCenter |

| Metric Type | Description | Data Sources Supporting the Metric |
|---|---|---|
| Edge transport node metrics | Starting with version 9, you can now view enhanced metrics taken from the the edge transport nodes of your NSX environment. This includes metrics retrieved in five minute intervals and more granular metrics retrieved every 20 seconds. Granular metrics can be separated in four categories:<br>• Node System metrics<br>• DP CPU Core metrics<br>• Node Process metrics<br>• Memory Pool metrics | NSX Manager |

## Comprehending Metric Data

You can view your metric data at different levels of granularity, based on the time range. For example, you can choose a one day view, which can be useful when troubleshooting. Or, choose a broader time range (for example, 30 days) so that you can see trends over time.

When you view metric data for different time ranges, you see different values indicated in the metric chart. This difference is because VCF Operations for networks displays different resolutions of data for different time ranges.

The default time range of any metric in VCF Operations for networks is 1 day and the resolution is 5 minutes. As the metric resolution becomes coarser, the metric data is down-sampled. That is, the resolution of the data is reduced. This is performed to create better metric graph visualizations by retaining only the important characteristics of the metric.

Time range and metric resolution for entity metrics:

| Time Range | Metric Resolution |
|---|---|
| 0 hours – 3.5 days | 5 minutes |
| 3.5 days – 15 days | 30 minutes |
| 15 days – 60 days | 2 hours |
| Beyond 60 days | 8 hours |

Time range and metric resolution for flow metrics:

| Time Range | Metric Resolution |
|---|---|
| 0 hours - 24 hours (within last 24 hours) | 5 minutes |
| 0 hours - 24 hours (beyond last 24 hours) | 30 minutes |
| 1 day – 15 days | 30 minutes |
| 15 days – 31 days | 2 hours |

Time range and metric resolution for special VM network utilization metrics:

| Time Range | Metric Resolution |
|---|---|
| 0 hours – 6 hours (within last 48 hours) | 20 seconds |
| 0 hours – 6 hours (beyond last 48 hours) | 5 minutes |
| 6 hours – 3.5 days | 5 minutes |
| 3.5 days – 15 days | 30 minutes |
| 15 days – 60 days | 2 hours |
| Beyond 60 days | 8 hours |

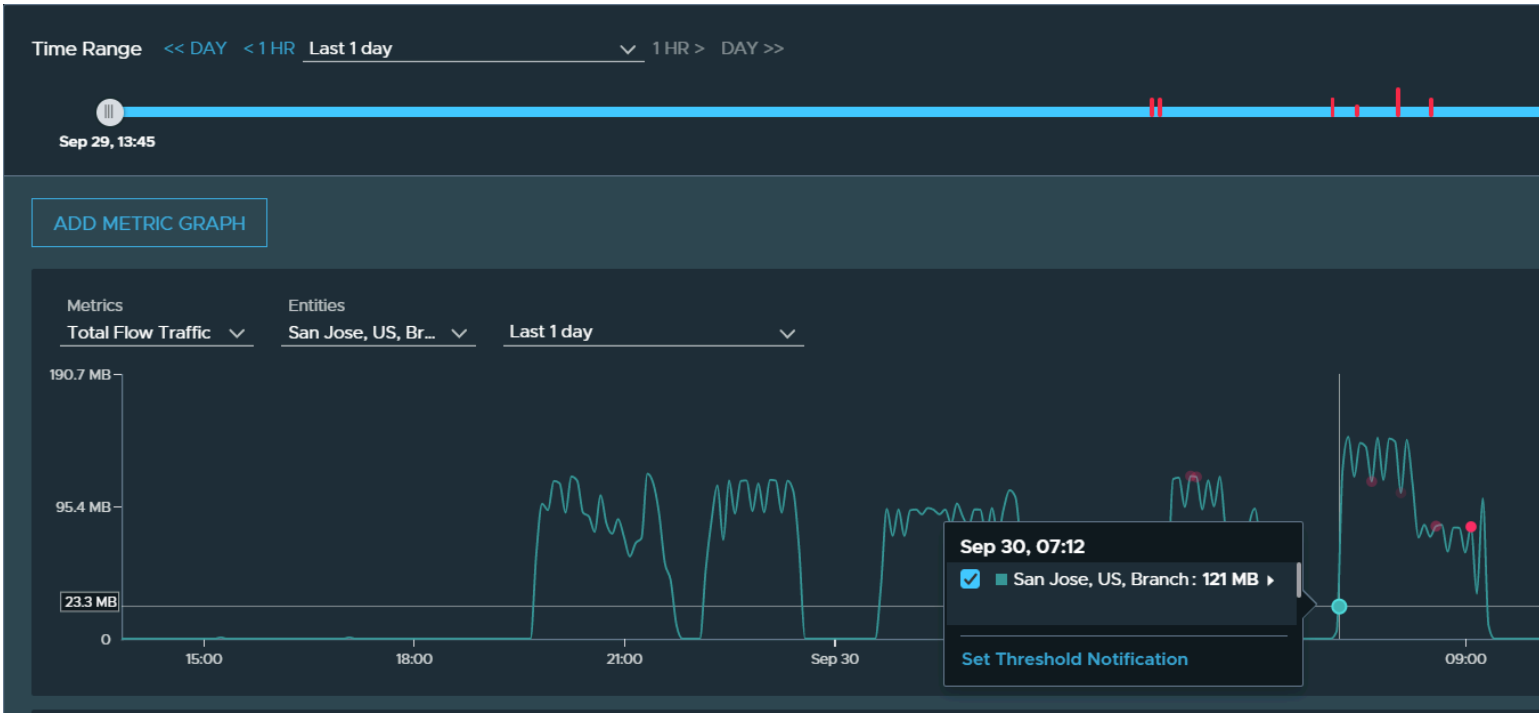
## Viewing Metric Data

In VCF Operations for networks, the metric data of an entity is displayed as line graph on the metric chart. You can point anywhere on the line graph to get informative tool tips. You can also co-relate multiple entities or two metrics graphs at the same time.

You can modify the time range of a metric by either using the slider or entering in a custom date and time. You can also adjust the time range for each entity within a metric.

You can select different metrics, entities, and time from the drop-down menu that is available in every metric chart. You can also adjust the view to a row view or a column view by using the view button in the top-right corner of the metrics chart. You can also export individual metrics graph in `CSV` format.

Here is an example metrics chart that shows the total flow of traffic in a VMware SD-WAN Edge device.



## Setting the Retention Interval

In VCF Operations for networks, you can choose how long the system retains metric data before automatically deleting it by setting the retention interval for each metric.

To set the retention interval of a metric, navigate to the **Settings** > **Data Management** page. To learn more, see Configure Data Retention Interval.

The minimum and maximum retention intervals defined by the system is as follows. Based on your business requirement, you can choose an interval between these values.

| Metric Type | Resolution | Minimum Retention | Maximum Retention |
|---|---|---|---|
| Entity metrics | 5 minutes | 1 month | 13 months |
| | 30 minutes | 1 month | 13 months |
| | 2 hours | 1 month | 13 months |

| Metric Type | Resolution | Minimum Retention | Maximum Retention |
|---|---|---|---|
| | 8 hours | 1 month | 13 months |
| Flow metrics<br>**Note:** You cannot edit the retention interval of flow metrics on the VCF Operations for networks UI. | 5 minute | 24 hours | 24 hours |
| | 30 minutes | 1 month | 1 month |
| | 2 hours | 1 month | 1 month |
| Health metrics | 5 minutes | 1 month | 13 months |
| | 30 minutes | 1 month | 13 months |
| | 2 hours | 1 month | 13 months |
| | 8 hours | 1 month | 13 months |
| VM network utilization metrics | 20 second<br>**Note:** You cannot edit the retention interval of VM network utilization metrics with 20 seconds resolution on the VCF Operations for networks UI. | 2 days | 2 days |
| | 5 minutes | 1 month | 13 months |
| | 30 minutes | 1 month | 13 months |
| | 2 hours | 1 month | 13 months |
| | 8 hours | 1 month | 13 months |

**Note:**

The retention interval you choose has a direct impact on disk space.

Reducing the log retention period deletes all logs older than the new retention period specified. For example, changing the retention period of the entity metrics from 6 months to 1 month deletes all logs older than a month. Therefore, consider backing up your log files before reducing the retention period.

Increasing the log retention period adds new logs to the collection. Therefore, check the available disk space and consider upgrading your disk space when increasing the log retention period.

## Entity Metrics

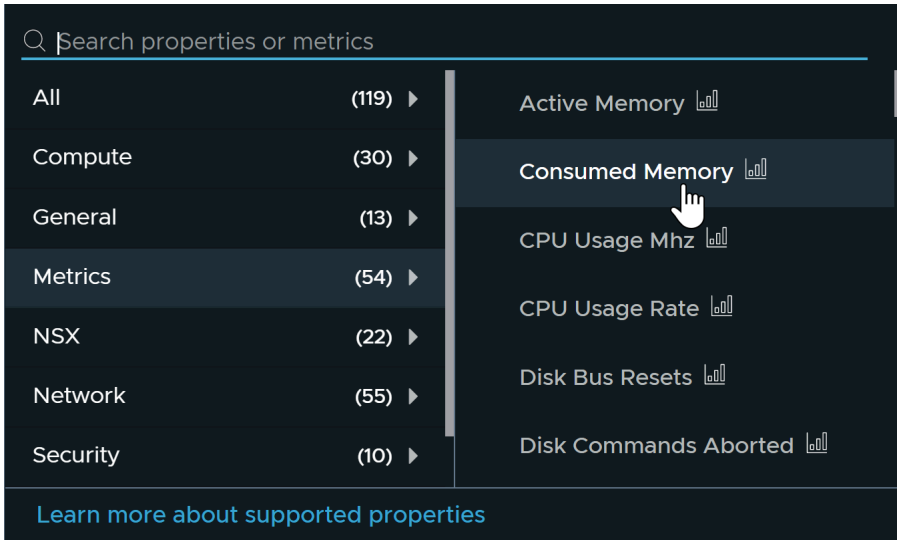
VCF Operations for networks collects entity metrics from data sources in your environment such as VMware vCenter, NSX to display information such as resource utilization, and performance.

To learn about the retention period of entity metrics, see Metric Definitions.

### Viewing Entity Metrics

To view the entity metrics on the user interface, do the following:

1. Enter the entity name on the search bar.
2. On the search result page, click **Add More Filters** under the **Filters** option.
3. Select **Metrics**. The entity related metrics are displayed to the right.
4. Select the metric you want to view.



## Application Metrics

VCF Operations for networks collects network and flow metrics for applications.

To view the application metrics on the user interface, do the following:

1. Enter `applications where name is set` on the search bar.
2. On the search result page, click **Add More Filters** under the **Filters** option.
3. Select **Metrics**. The application metrics are displayed to the right.
4. Select the metric you want to view.

The following metrics are available for each application in your VCF Operations for networks environment.

| Metric Name | Metric API Name | Description |
|---|---|---|
| App/Tier TCP Retransmitted Packets | net.tcpRetransmitedPackets.delta.summation.number | Total number of retransmitted packets in all the flows of the application. |
| Median TCP RTT (ms) | net.p50FlowAvgTcpRtt.absolute.average.microsecond | Median round-trip time of all TCP flows associated with an application. |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of packets transmitted and received from an application. |
| Network Rx Rate (kbps) | net.received.rate.average.kiloBitsPerSecond | Average rate at which data is received across all endpoints of the application. |
| Network Tx Rate (kbps) | net.transmitted.rate.average.kiloBitsPerSecond | Average rate at which data is transmitted from all endpoints in the application. |
| Rx Flow Drops | flow.droppedRx.delta.summation.number | Total number of dropped incoming flows to total number of incoming flows. |
| TCP Retransmitted Packet Ratio (%) | net.tcpRetransmitedPackets.ratio.average.percent | Percentage of retransmitted packets in all the flows associated with an application. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | Total number of bytes received by the application. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | Total number of bytes transmitted by the application. |
| Tx Flow Drops | flow.droppedTx.delta.summation.number | Total number of dropped outgoing flows to total number of outgoing flows. |

## AWS Virtual Private Cloud Metrics

VCF Operations for networks collects flow metrics for AWS Virtual Private Cloud (VPC) instances.

To view AWS VPC metrics on the user interface, do the following:

1. Enter `AWS Virtual Private Cloud` on the search bar.
2. On the search result page, select an AWS VPC of your choice.
3. On the respective AWS VPC page, select the **Metrics** tab.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Outbound Expire Flow Drop Count | flow.fiveTupleExpireOutbound.delta.summation.number | Number of five tuples dropped because of reaching the maximum outbound limit for source IP addresses in flows. |
| Wrong Collector Flow Drop Count | flow.rawRecordReporterWrongCollector.delta.summation.number | Number of raw flow records dropped as the flow records were reported on a wrong type of VCF Operations for networks collector. |

## Datastore Metrics

VCF Operations for networks collects datastore metrics to learn about storage space use and to check metric trends to identify spikes or abnormal growth.

| Metric Name | Metric API Name | Decription |
|---|---|---|
| Capacity | datastore.capacity.absolute.latest.bytes | Total storage capacity of the datastore. |
| Committed Space | datastore.committed.absolute.latest.bytes | Storage space on the datastore that is used by the virtual machine to store disks, logs, snapshots, and configuration files. |
| Free Space | datastore.freespace.absolute.latest.bytes | Free space available on the datastore. |
| Free Space Percent (%) | datastore.freespace.absolute.latest.percent | Ratio of free storage space to the total storage capacity on the datastore. |
| Provisioned Space | datastore.provisioned.absolute.latest.bytes | Storage capacity allocated for all VMs on the datastore. |
| Provisioned Space Percent (%) | datastore.provisioned.absolute.latest.percent | Ratio of the provisioned space to the total storage capacity for the datastore. |
| Read IOPS | datastore.numberReadAveraged.rate.average.number | Average number of read commands issued per second on the datastore. |
| Read Latency (ms) | datastore.weightedTotalReadLatency.absolute.average.millisecond | Average read latency over a period of 24 hours. |
| Read Rate (kbps) | datastore.read.rate.average.kiloBytesPerSecond | Read throughput averaged over a period of 24 hours. |
| RW IOPS | datastore.numberRWAveraged.rate.average.number | Average number of read and write commands issued per second over a period of 24 hours. |
| RW Rate (kbps) | datastore.usage.rate.average.kiloBytesPerSecond | Read and write throughput averaged over a period of 24 hours. |
| Uncommitted Space | datastore.uncommitted.absolute.latest.bytes | Additional storage space that is potentially used by the VM on the datastore. This storage space is needed for thin-provisioned VMs to allow lazily allocated disks to expand or storage for swap. |
| Used Space | datastore.usedspace.absolute.latest.bytes | Storage capacity used by VMs on the datastore. |
| Used Space Percent (%) | datastore.usedspace.absolute.latest.percent | Ratio of used storage capacity to the total storage capacity on the datastore. |

| Metric Name | Metric API Name | Decription |
|---|---|---|
| Write IOPS | datastore.numberWriteAveraged.rate.average.number | Average number of write commands issued per second on the datastore. |
| Write Latency (ms) | datastore.weightedTotalWriteLatency.absolute.average.millisecond | Average write latency over a period of 24 hours. |
| Write Rate (kbps) | datastore.write.rate.average.kiloBytesPerSecond | Write throughput averaged over a period of 24 hours. |

## Device Interface Service Metrics

The device interface service metrics provide information about the traffic of the interface of a device accessing a particular service.

| Metric Name | Metric API Name | Decription |
|---|---|---|
| Bytes | net.serviceTotalBytes.delta.summation.bytes | Total incoming and outgoing traffic from a device interface accessing a service. |
| Egress Bytes | net.serviceEgress.delta.summation.bytes | Total outgoing traffic from a device interface accessing a service. |
| Ingress Bytes | net.serviceIngress.delta.summation.bytes | Total incoming traffic to a device interface accessing a service. |
| Low Priority Bytes | net.serviceLowPriorityTotalBytes.delta.summation.bytes | Total incoming and outgoing traffic of low priority flows of a device interface accessing a service. |
| Low Priority Egress Bytes | net.serviceLowPriorityEgress.delta.summation.bytes | Total outgoing traffic of low priority flows from a device interface accessing a service. |
| Low Priority Ingress Bytes | net.serviceLowPriorityIngress.delta.summation.bytes | Total incoming traffic of low priority flows to a device interface accessing a service. |

## Host Metrics

VCF Operations for networks collects many metrics for hosts, including CPU usage, datastore, memory, network, and disk metrics.

### CPU Usage Metrics for Hosts

These metrics provide information about the CPU use on the host.

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| CPU Co-stop Time (%) | cpu.costop.delta.summation.millisecond | Percentage of time the host is ready, but unable to run due to co-scheduling constraints. | |
| CPU Ready Time (%) | cpu.ready.delta.summation.millisecond | Percentage of time the VM was waiting in line to use the CPU on the host. | |
| CPU Run Time (ms) | cpu.run.delta.summation.millisecond | Total time spent in `run` state by all VMs of this host. | |
| CPU Usage (MHz) | cpu.usagemhz.rate.average.megaHertz | Average CPU use in megahertz. | Yes |

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| CPU Usage Rate (%) | cpu.usage.rate.average.percent | Percentage of the CPU used out of its total capacity. | Yes |
| CPU Wait Time (ms) | cpu.wait.delta.summation.millisecond | Total CPU time spent in wait state such as CPU idle, CPU swap wait, and CPU I/O wait. | |
| Uptime (s) | sys.uptime.absolute.latest.second | Total time elapsed since the last system startup. | |

**Network Metrics for Hosts**

These metrics provide information about the network performance of the host.

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Dropped Rx Packets | net.droppedRx.delta.summation.number | Average ratio of the number of dropped Rx packets to the total number of Rx packets. | Yes |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | Average ratio of the number of dropped Tx packets to the total number of Tx packets. | Yes |
| Max IO Latency | datastore.maxTotalLatency.absolute.latest.millisecond | Highest latency value across all datastores connected to the host. | |
| Max Network Traffic Rate (Kbps) | net.usage.rate.maximum.kiloBitsPerSecond | Maximum data transmission rate on the host over any five minute interval in the selected duration. Maximum network rate includes both transmitted and received data. | Yes |
| Max Network Tx Rate (Kbps) | net.transmitted.rate.maximum.kiloBitsPerSecond | Maximum data transmission rate on the host over any five minute interval in the selected duration. | Yes |
| Max Packet Drop Ratio (%) | net.packetDrop.ratio.maximum.percent | Maximum ratio of total packets dropped to total number of packets received over any five minute interval in the selected duration. | Yes |
| Max Packet Drops | net.droppedTotal.delta.maximum.number | Maximum number of dropped packets over any five minute interval in the selected duration. | yes |
| Multicast Rx Packets | net.multicastRx.delta.summation.number | Total number of multicast packets received across all pNICs (physical network adapters) during the sampling interval. | Yes |
| Multicast Tx Packets | net.multicastTx.delta.summation.number | Total number of multicast packets transmitted across all pNICs during the sampling interval. | Yes |

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Network Max Rx Rate (Kbps) | net.received.rate.maximum.kiloBitsPerSecond | Maximum network data receive rate on the host over any five minute interval in the selected duration. | Yes |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of packets transmitted and received during the interval across all pNICs. | Yes |
| Network Packet Drop Percent (%) | net.packetDrop.ratio.average.percent | Ratio of total number of dropped packets to total number of packets. | Yes |
| Network Packet Drops | net.droppedTotal.delta.summation.number | Total number of packet drops on the host. | Yes |
| Network Rx Rate (Kbps) | net.received.rate.average.kiloBitsPerSecond | Average rate at which data was received during the time interval. | Yes |
| Network Traffic Rate (Kbps) | net.usage.rate.average.kiloBitsPerSecond | Average rate of received and transmitted traffic during the time interval. | Yes |
| Network Tx Rate (Kbps) | net.transmitted.rate.average.kiloBitsPerSecond | Average rate at which data was transmitted during the time interval. | Yes |
| Outbound Expire Flow Drop Count | flow.fiveTupleExpireOutbound.delta.summation.number | Number of five tuples dropped due to the number of source IP addresses of flows reaching the outbound limit.<br>The outbound limit for TCP flows is 1000 (allowed) and 50 (denied), and the outbound limit of UDP flows is 500 (allowed) and 50 (denied).<br>This is a protection mechanism to make sure that the entities do not overload the total flow limit. | |
| Rx Broadcast Packets | net.broadcastRx.delta.summation.number | Number of broadcast packets received during a specified time interval. | Yes |
| Rx Broadcast Ratio | net.broadcastByRx.ratio.average.percent | Percent of broadcast packets received during a specified time interval. | Yes |
| Rx Packet Drop Percent (%) | net.packetDropRx.ratio.average.percent | Ratio of total number of dropped Rx packets to total number of Rx packets. | Yes |
| Rx Packets | net.packetsRx.delta.summation.number | Average number of received packets during the time interval. | Yes |
| Total Disk Latency (ms) | disk.totalLatency.absolute.average.millisecond | Average total latency (sum of kernel and device latency) for both read and write commands. | |
| Total Network Traffic | net.usage.delta.summation.kiloBytes | Sum of data transmitted and received for all the NIC instances of the host. | Yes |

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Tx Broadcast Packets | net.broadcastTx.delta.summation.number | Number of broadcast packets transmitted during a specified time interval. | Yes |
| Tx Broadcast Ratio | net.broadcastByTx.ratio.average.percent | Average percent of broadcast packets transmitted during a specified time interval. | Yes |
| Tx Packet Drop Percent (%) | net.packetDropTx.ratio.average.percent | Ratio of total number of dropped Tx packets to total number of Tx packets. | Yes |
| Tx Packets | net.packetsTx.delta.summation.number | Average number of transmitted packets during the time interval. | Yes |
| Unicast Rx Packets | net.unicastRx.delta.summation.number | Total number of unicast packets received by the host. | Yes |
| Unicast Tx Packets | net.unicastTx.delta.summation.number | Total number of unicast packets transmitted by the host. | Yes |
| Wrong Collector Flow Drop Count | flow.rawRecordReporterWrongCollector.delta.summation.number | Number of raw flow records dropped as they were reported on a wrong type of VCF Operations for networks collector.<br>Physical flows must be reported to physical proxies. Other flows must be reported to non-physical proxies. | |

## Datastore Metrics for Hosts

These metrics provide information about the datastore use of the host.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Read IOPS | datastore.numberReadAveraged.rate.average.number | Average number of read commands issued per second during the collection interval. |
| Read Latency (ms) | datastore.totalReadLatency.absolute.average.millisecond | Average latency of each read operation issued by the link through which the host is connected to the datastore. |
| Read Rate (Kbps) | datastore.read.rate.average.kiloBytesPerSecond | Average number of kilobytes read by the link through which the host is connected to the datastore. |
| RW IOPS | datastore.numberRWAveraged.rate.average.number | Average number of read and write commands issued per second during the collection interval. |
| RW Rate (Kbps) | datastore.usage.rate.average.kiloBytesPerSecond | The aggregated input rates and output rates of the link through which the host is connected to the datastore. |
| Write IOPS | datastore.numberWriteAveraged.rate.average.number | Average number of write commands issued per second during the collection interval. |
| Write Latency (ms) | datastore.totalWriteLatency.absolute.average.millisecond | Average latency of each write operation issued by the link through which the host is connected to the datastore. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Write Rate (Kbps) | datastore.write.rate.average.kiloBytesPerSecond | Average number of kilobytes written by the link through which the host is connected to the datastore. |

## Memory Metrics for Hosts

These metrics provide information about memory use and allocation on the host.

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Memory Balloon | mem.vmmemctl.absolute.average.kiloBytes | The amount of memory currently claimed by the balloon driver.<br>This metric indicates that the host is taking memory from less needful VMs, and allocating it to those VMs where there is an increased memory requirement. | |
| Memory State (0-3) | mem.state.absolute.latest.number | Overall state of the memory.<br>The value is an integer between 0 (high) and 3 (low). | |
| Memory Swap Used | mem.swapused.absolute.average.kiloBytes | The amount of swap memory currently in use.<br>A large amount of swap memory does not indicate a performance problem. Check the swap rates to verify if the guest is actively in need of more memory than that is available. | |
| Memory Swap-In Rate (Kbps) | mem.swapinRate.rate.average.kiloBytesPerSecond | Rate at which the memory is swapped from disk to active memory during the time interval. | |
| Memory Swap-Out Rate (Kbps) | mem.swapoutRate.rate.average.kiloBytesPerSecond | Rate at which the memory is being swapped from active memory to the disk during the time interval. | |
| Memory Usage Rate (%) | mem.usage.absolute.average.percent | Percentage of memory used from the available machine memory. | Yes |
| Reserved Memory (KB) | mem.reservedCapacity.absolute.average.megaBytes | Amount of reserved memory by powered-on VMs and the memory used for running VMware vSphere services on the host. | |
| Overhead Memory (KB) | mem.overhead.absolute.average.kiloBytes | Memory overhead reported by the host.<br>Memory overhead is the total memory allocated to powered on VMs beyond its reserved memory and the memory used for running vSphere services on the host. | |
| Consumed Memory (KB) | mem.consumed.absolute.average.kiloBytes | Total memory consumed by the VMs and VMware vSphere services in the host. | |

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Active Memory (KB) | mem.active.absolute.average.kiloBytes | Total memory actively used by the host.<br>Total memory includes memory used by VMs and VMware vSphere services running on the host. The VMkernel estimates the total memory based on recently touched memory pages. | Yes |

## Disk Metrics for Hosts

These metrics provide information about disk use of the host.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Average Read Latency (ms) | disk.deviceReadLatency.absolute.average.millisecond | Average latency of each read operation issued to complete a Small Computer System Interface (SCSI) command from the physical device. |
| Average Write Latency (ms) | disk.deviceWriteLatency.absolute.average.millisecond | Average latency of each write operation issued to complete a SCSI command from the physical device. |
| Disk Bus Resets | disk.busResets.delta.summation.number | Number of SCSI-bus reset commands issued during the collection interval. |
| Disk Commands Aborted | disk.commandsAborted.delta.summation.number | Number of SCSI commands aborted during the collection interval. |
| Disk Device Latency (ms) | disk.deviceLatency.absolute.average.millisecond | Average amount of time taken to complete a SCSI command from the physical device. |
| Disk Kernel Latency (ms) | disk.kernelLatency.absolute.average.millisecond | Average amount of time spent by the VMkernel processing each SCSI command. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Disk Queue Depth | disk.queueDepth.absolute.latest.number | Maximum queue depth during the collection interval. |
| Disk Queue Latency | disk.queueLatency.absolute.average.millisecond | Average amount of time spent in the VMkernel queue, per SCSI command, during the collection interval. |
| Disk Reads (KB) | disk.read.rate.average.kiloBytesPerSecond | Average number of reads through this link. |
| Disk Writes (KB) | disk.write.rate.average.kiloBytesPerSecond | Average number of writes through this link. |
| Read IOPS | disk.numberReadAveraged.rate.average.number | Average number of reads issued to complete a SCSI command through this link. |
| RW IOPS | disk.numberRWAveraged.rate.average.number | Average number of reads or writes issued to complete a SCSI command through this link. |
| Total Disk Latency (ms) | disk.totalLatency.absolute.average.millisecond | Average amount of time taken during the collection interval to process a SCSI command issued by the guest operating system to the VM. |
| Write IOPS | disk.numberWriteAveraged.rate.average.number | Average number of writes issued to complete a SCSI command through this link. |

## HCX Tunnel Metrics

The HCX tunnel metrics provide information about the network performance of HCX tunnels.

| Metric Name | Metric API Name | Decription |
|---|---|---|
| Dropped Rx Packets | net.droppedRx.delta.summation.number | Number of dropped Rx packets in the selected duration. |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | Number of dropped Tx packets in the selected duration. |

| Metric Name | Metric API Name | Decription |
|---|---|---|
| Max Network Traffic Rate (kbps) | net.usage.rate.maximum.kiloBitsPerSecond | Maximum network usage rate on the HCX tunnel over any five minute interval in the selected duration. |
| Max Network Tx Rate (kbps) | net.transmitted.rate.maximum.kiloBitsPerSecond | Maximum data transmission rate on the HCX tunnel over any five minute interval in the selected duration. |
| Network Max Rx Rate (kbps) | net.received.rate.maximum.kiloBitsPerSecond | Maximum network data receive rate on the HCX tunnel over any five minute interval in the selected duration. |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of packets transmitted and received during the time interval. |
| Network Rx Rate (kbps) | net.received.rate.average.kiloBitsPerSecond | Average rate at which the data is received during the time interval. This metric represents the bandwidth of the network. |
| Network Traffic Rate (kbps) | net.usage.rate.average.kiloBitsPerSecond | Average rate of received and transmitted traffic during the time interval. |
| Network Tx Rate (kbps) | net.transmitted.rate.average.kiloBitsPerSecond | Average rate at which the data is transmitted during the time interval. This metric represents the bandwidth of the network. |
| Rx Packet Errors | net.errorRx.delta.summation.number | Number of received packet errors during the time interval. |
| Rx Packet Per Second | net.ppsRx.rate.average.number | Number of packets received per second during the time interval. |
| Rx Packets | net.packetsRx.delta.summation.number | Average number of received packets during the time interval. |
| Total Network Traffic | net.usage.delta.summation.kiloBytes | Sum of data transmitted and received during the time interval. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | Sum of bytes received during the time interval. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | Sum of bytes transmitted during the time interval. |
| Tx Packet Errors | net.errorTx.delta.summation.number | Number of transmitted packet errors during the time interval. |
| Tx Packet Per Second | net.ppsTx.rate.average.number | Number of packets transmitted per second during the time interval. |
| Tx Packets | net.packetsTx.delta.summation.number | Average number of transmitted packets during the time interval. |

### Kubernetes Service Metrics

Kubernetes service metrics provide information about the number of pods and nodes deployed for a particular service.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Nodes Count | sys.kubernetes.service.nodes.absolute.latest.number | Number of Kubernetes nodes deployed for a service in a five minute interval. |
| Pods Count | sys.kubernetes.service.pods.absolute.latest.number | Number of Kubernetes pods deployed for a service in a five minute interval. |

## Metrics for NSX Policy Manager

VCF Operations for networks collects many metrics for NSX policy manager including the firewall metrics.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Distributed Firewall Application Rules Count | usage.distributedFirewallApplicationRuleCount.absolute.maximum.number | Number of distributed firewall rules of category application. |
| Distributed Firewall Emergency Rules Count | usage.distributedFirewallEmergencyRuleCount.absolute.maximum.number | Number of distributed firewall rules of category emergency. |
| Distributed Firewall Environment Rules Count | usage.distributedFirewallEnvironmentRuleCount.absolute.maximum.number | Number of distributed firewall rules of category environment. |
| Distributed Firewall Ethernet Rules Count | usage.distributedFirewallEthernetRuleCount.absolute.maximum.number | Number of distributed firewall rules of category Ethernet. |
| Distributed Firewall Infrastructure Rules Count | usage.distributedFirewallInfrastructureRuleCount.absolute.maximum.number | Number of distributed firewall rules of category infrastructure. |

## Metrics for NSX-T Dropped Packets

VCF Operations for networks collects flow metrics for NSX-T Dropped Packets.

| | | |
|---|---|---|
| Blocked Rx Packets | net.blockedRx.delta.summation.number | Number of blocked received packets due to standby interface. |
| Blocked Tx Packets | net.blockedTx.delta.summation.number | Number of blocked transmitted packets due to standby interface. |
| Duplicate Address Detected Dropped Rx Packets | net.dadDroppedRx.delta.summation.number | Total number of received detected duplicate address for blocked packets in the selected duration. |
| Duplicate Address Detected Dropped Tx Packets | net.dadDroppedTx.delta.summation.number | Total number of transmitted detected duplicate address in blocked packets for the selected duration. |
| Destination Unsupported Dropped Rx Packets | net.destUnsupportedDroppedRx.delta.summation.number | Number of received packets that were dropped during the collection interval. |
| Destination Unsupported Dropped Tx Packets | net.destUnsupportedDroppedTx.delta.summation.number | Number of transmitted packets that were dropped because the destination address (such as an IP address or MAC address) was unreachable or invalid. |
| Firewall Dropped Rx Packets | net.firewallDroppedRx.delta.summation.number | Number of received packets that were dropped by the firewall. |
| Firewall Dropped Tx Packets | net.firewallDroppedTx.delta.summation.number | Number of transmitted packets dropped due to non-firewall during the selected interval of router interface. |

| | | |
|---|---|---|
| Fragmentation Dropped Rx Packets | net.fragNeededDroppedRx.delta.summation.number | Number of received packets dropped due to fragmentation needed. |
| Fragmentation Dropped Tx Packets | net.fragNeededDroppedTx.delta.summation.number | Number of transmitted packets dropped due to fragmentation needed. |
| IPSec Dropped Rx Packets | net.ipsecDroppedRx.delta.summation.number | Number of received packets dropped by IPSec. |
| IPSec Dropped Tx Packets | net.ipsecDroppedTx.delta.summation.number | Number of transmitted packets dropped by IPSec. |
| IPSec Security Association Absence Dropped Rx Packets | net.ipsecNoSaDroppedRx.delta.summation.number | Number of received packets dropped due to IPSec no security association. |
| IPSec Security Association Absence Dropped Tx Packets | net.ipsecNoSaDroppedTx.delta.summation.number | Number of transmitted packets dropped due to IPSec no security association. |
| IPSec VTI Absence Dropped Rx Packets | net.ipsecNoVtiDroppedRx.delta.summation.number | Number of received packets dropped due to no VTI is associated with IPSec. |
| IPSec VTI Absence Dropped Tx Packets | net.ipsecNoVtiDroppedTx.delta.summation.number | Number of transmitted packets dropped due to no VTI is associated with IPSec. |
| IPSec Policy Block Dropped Rx Packets | net.ipsecPolicyBlockDroppedRx.delta.summation.number | Number of received packets dropped due to IPSec policy blocked. |
| IPSec Policy Block Dropped Tx Packets | net.ipsecPolicyBlockDroppedTx.delta.summation.number | Number of transmitted packets dropped due to IPSec policy blocked. |
| IPSec Policy Error Dropped Rx Packets | net.ipsecPolicyErrorDroppedRx.delta.summation.number | Number of received packets dropped due to IPSec policy error. |
| IPSec Policy Error Dropped Tx Packets | net.ipsecPolicyErrorDroppedTx.delta.summation.number | Number of transmitted packets dropped due to IPSec policy error. |
| IPV6 Dropped Rx Packets | net.IPV6DroppedRx.delta.summation.number | Number of received IPV6 packets dropped. |
| IPV6 Dropped Tx Packets | net.IPV6DroppedTx.delta.summation.number | Number of transmitted IPV6 packets dropped. |
| Kernel Nic Interface Dropped Rx Packets | net.KNIDroppedRx.delta.summation.number | Number of received packets dropped by DPDK kernal NIC interface. |
| Kernel Nic Interface Dropped Tx Packets | net.KNIDroppedTx.delta.summation.number | Number of transmitted packets dropped by DPDK kernal NIC interface. |
| Unsupported L4 Port Dropped Rx Packets | net.L4PortUnsupportedDroppedRx.delta.summation.number | Number of received packets dropped due to unsupported L4 port. |
| Unsupported L4 Port Dropped Tx Packets | net.L4PortUnsupportedDroppedTx.delta.summation.number | Number of transmitted packets dropped due to unsupported L4 port. |
| Malformed Dropped Rx Packets | net.malformedDroppedRx.delta.summation.number | Number of received packets dropped due to malformed. |

| | | |
|---|---|---|
| Malformed Dropped Tx Packets | net.malformedDroppedTx.delta.summation.number | Number of transmitted packets dropped due to malformed. |
| ARP Absence Dropped Rx Packets | net.noARPDroppedRx.delta.summation.number | Number of received packets dropped due to the absence of ARP. |
| ARP Absence Dropped Tx Packets | net.noARPDroppedTx.delta.summation.number | Number of transmitted packets dropped due to the absence of ARP. |
| Linked Port Absence Dropped Rx Packets | net.noLinkedDroppedRx.delta.summation.number | Number of received packets dropped due to the absence of linked port. |
| Linked Port Absence Dropped Tx Packets | net.noLinkedDroppedTx.delta.summation.number | Number of transmitted packets dropped due to the absence of linked port. |
| Insufficient Memory Dropped Rx Packets | net.noMemoryDroppedRx.delta.summation.number | Number of received packets dropped due to insufficient memory. |
| Insufficient Memory Dropped Tx Packets | net.noMemoryDroppedTx.delta.summation.number | Number of transmitted packets dropped due to insufficient memory. |
| Receiver Absence Dropped Rx Packets | net.noReceiverDroppedRx.delta.summation.number | Number of received packets dropped due to absence of receiver. |
| Receiver Absence Dropped Tx Packets | net.noReceiverDroppedTx.delta.summation.number | Number of transmitted packets dropped due to absence of receiver. |
| Route Absence Dropped Rx Packets | net.noRouteDroppedRx.delta.summation.number | Number of received packets dropped due to absence of route. |
| Route Absence Dropped Tx Packets | net.noRouteDroppedTx.delta.summation.number | Number of transmitted packets dropped due to absence of route. |
| Non IP Dropped Rx Packets | net.nonIPDroppedRx.delta.summation.number | Number of non IP received packets dropped. |
| Non IP Dropped Tx Packets | net.nonIPDroppedTx.delta.summation.number | Number of non IP transmitted packets dropped. |
| Unsupported Protocol Dropped Rx Packets | net.protoUnsupportedDroppedRx.delta.summation.number | Number of received packets dropped due to unsupported protocol. |
| Unsupported Protocol Dropped Tx Packets | net.protoUnsupportedDroppedTx.delta.summation.number | Number of transmitted packets dropped due to unsupported protocol. |
| Redirect Dropped Rx Packets | net.redirectDroppedRx.delta.summation.number | Number of redirect received packets dropped. |
| Redirect Dropped Tx Packets | net.redirectDroppedTx.delta.summation.number | Number of redirect transmitted packets dropped. |
| Service Insert Dropped Rx Packets | net.serviceInsertDroppedRx.delta.summation.number | Number of service insert received packets dropped. |
| Service Insert Dropped Tx Packets | net.serviceInsertDroppedTx.delta.summation.number | Number of service insert transmitted packets dropped. |
| TTL Exceeded Dropped Rx Packets | net.ttlExceededDroppedRx.delta.summation.number | Number of time to live exceeded received packets dropped. |

| | | |
|---|---|---|
| TTL Exceeded Dropped Tx Packets | net.ttlExceededDroppedTx.delta.summation.number | Number of time to live exceeded transmitted packets dropped. |
| Non Firewall Dropped Rx Packets | net.nonFirewallDroppedRx.delta.summation.number | Number of received packets dropped due to non-firewall during the selected interval of router interface. |
| Non Firewall Dropped Tx Packets | net.nonFirewallDroppedTx.delta.summation.number | Number of transmitted packets dropped due to non-firewall during the selected interval of router interface |
| Non Firewall Tx Packet Drop Percent | net.nonFirewallDroppedRx.ratio.average.percent | Average ratio of transmitted packet drops due to non firewall to the total transmitted packets. |
| Firewall Rx Packet Drop Percent | net.firewallDroppedRx.ratio.average.percent | Average ratio of received packet drops due to firewall to the total received packets. |
| Max Firewall Rx Packet Drop Percent | net.firewallDroppedRx.ratio.maximum.percent | Percentage of maximum received packets dropped due to firewall to the total number of received packets over 5 minutes interval in the selected duration. |
| Max Non Firewall Rx Packet Drop Percent | net.nonFirewallDroppedRx.ratio.maximum.percent | Percentage of maximum received packets dropped due to non firewall to the total number of received packets over 5 minutes interval in the selected duration. |
| Firewall Tx Packet Drop Percent | net.firewallDroppedTx.ratio.average.percent | Average ratio of transmitted packet drops due to firewall to the total transmitted packets. |
| Non Firewall Tx Packet Drop Percent | net.nonFirewallDroppedTx.ratio.average.percent | Average ratio of transmitted packet drops due to non firewall to the total transmitted packets. |
| Max Firewall Tx Packet Drop Percent | net.firewallDroppedTx.ratio.maximum.percent | Percentage of maximum transmitted packets dropped due to firewall to the total number of transmitted packets in the selected duration. |
| Max Non Firewall Tx Packet Drop Percent | net.nonFirewallDroppedTx.ratio.maximum.percent | Percentage of maximum transmitted packets dropped due to non firewall to the total number of transmitted packets in the selected duration. |

## Metrics for Avi Load Balancer

VCF Operations for networks collects many metrics for Avi Load Balancer, including controller metrics, pool metrics, pool member metrics, service engine metrics, and virtual service metrics.

## Controller Metrics

| Metric Name | Metric API Name | Description |
|---|---|---|
| CPU Usage Rate (%) | cpu.usage.rate.average.percent | Average percentage of the CPU used out of its total capacity.<br>**Note:**<br>This metric provides the host's view of the CPU usage and not the guest operating system view.<br>It is the average CPU utilization over all available virtual CPUs in the virtual machine. |
| Disk Usage Rate | disk.used.absolute.latest.percent | Average percentage of the disk used out of its total capacity. |
| Memory Usage Rate | mem.usage.absolute.average.percent | Average percentage of the memory used out of the total configured memory. |

## Pool and Pool Member Metrics

| Metric Name | Metric API Name | Description |
|---|---|---|
| Current Connections | net.lbPoolCurrentConnections.absolute.latest.number | Number of current connections processed by this pool during the time interval. |
| Health Score | nsxalb.healthScore.absolute.latest.number | The score indicating the health of the pool. |
| Lossy Connections | nsxalb.lossyConnections.delta.summation.number | Number of lossy connections during the time interval between the service engine and the server. |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of received and transmitted packets processed by this pool during the time interval. |
| Network Rx Rate (kbps) | net.received.rate.average.kiloBitsPerSecond | Average rate of received packets processed by this pool during the time interval. |
| Network Traffic Rate (kbps) | net.usage.rate.average.kiloBitsPerSecond | Average rate of received and transmitted packets processed by this pool during the time interval. |
| Network Tx Rate (kbps) | net.transmitted.rate.average.kiloBitsPerSecond | Average rate of transmitted packets processed by this pool during the time interval. |
| Rx Packets | net.packetsRx.delta.summation.number | Total number of received packets processed by this pool during the time interval. |
| Server Responses | nsxalb.l7ServerResponse.delta.summation.number | Total number of server HTTP responses handled by the pool during the time interval. |
| Tx Packets | net.packetsTx.delta.summation.number | Total number of transmitted packets processed by this pool during the time interval. |

## Service Engine Metrics

| Metric Name | Metric API Name | Description |
|---|---|---|
| CPU Usage Rate (%) | cpu.usage.rate.average.percent | Average percentage of the CPU used out of its total capacity.<br>**Note:**<br>This metric provides the host's view of the CPU usage and not the guest operating system view.<br>It is the average CPU utilization over all available virtual CPUs in the virtual machine. |
| Dropped Rx Packets | net.droppedRx.delta.summation.number | Average number of received packets in Avi Load Balancer virtual services and Avi Load Balancer non-virtual services dropped during the selected duration. |
| Health Score | nsxalb.healthScore.absolute.latest.number | The score indicating the health of the service engine. |
| Memory Usage Rate (%) | mem.usage.absolute.average.percent | Average percentage of the memory used out of the total configured memory. |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of received and transmitted packets processed by all the vNICs of the service engine (VM) during the selected duration. |
| Network Rx Rate (kbps) | net.received.rate.average.kiloBitsPerSecond | Average rate of received packets across all the VNICs of the service engine. |
| Network Traffic Rate (kbps) | net.usage.rate.average.kiloBytesPerSecond | Average rate of received and transmitted packets across all the VNICs of the service engine. |
| Network Tx Rate (kbps) | net.transmitted.rate.average.kiloBitsPerSecond | Average rate of transmitted packets across all the VNICs of the service engine. |
| Network Tx Rate (kbps) | net.transmitted.rate.average.kiloBytesPerSecond | Average rate of transmitted packets across all the VNICs of the service engine. |
| Rx Packets | net.packetsRx.delta.summation.number | Number of packets received by all the vNICs of the service engine (VM) during the selected duration. |
| Session Count | net.connection.delta.summation.number | Number of connections to the service engine during the time interval.<br>The number of connections include the dropped connections and the connections lost due to policy drops. |
| Tx Packets | net.packetsTx.delta.summation.number | Number of packets transmitted by all the vNICs of the service engine during the selected duration. |

**Virtual Service Metrics**

| Metric Name | Metric API Name | Description |
|---|---|---|
| Client Responses | nsxalb.l7ClientResponses.delta.summation.number | Number of HTTP responses sent to clients during the time interval. |
| Current Connections | net.lbVirtSvrCurrentConnections.absolute.latest.number | Number of connections completed during the time interval. |
| Health Score | nsxalb.healthScore.absolute.latest.number | The score indicating the health of the virtual service. |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of received and transmitted packets during the time interval. |
| Network Rx Rate (kbps) | net.received.rate.average.kiloBitsPerSecond | Average rate of received packets during the time interval. |
| Network Traffic Rate (kbps) | net.usage.rate.average.kiloBitsPerSecond | Average rate of received and transmitted packets during the time interval. |
| Network Tx Rate (kbps) | net.transmitted.rate.average.kiloBitsPerSecond | Average rate of transmitted packets during the time interval. |
| New Connections | net.newConnections.delta.summation.number | Number of new connections established during the time interval. |
| Rx Packets | net.packetsRx.delta.summation.number | Number of received packets during the time interval. |
| SSL Connections | nsxalb.sslConnections.delta.summation.number | Number of new SSL transactions during the time interval excluding session reuse and errored connection attempts. |
| Tx Packets | net.packetsTx.delta.summation.number | Number of transmitted packets during the time interval. |

## Port Channel Metrics

The port channel metrics provide information about the network performance of the port channel.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Discarded Rx Packets | net.discardedRx.delta.summation.number | Number of discarded inbound packets. |
| Discarded Tx Packets | net.discardedTx.delta.summation.number | Number of discarded outbound packets. |
| Dropped Rx Packets | net.droppedRx.delta.summation.number | Number of received packets that were dropped during the collection interval. |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | Number of transmitted packets that were dropped during the collection interval. |
| FCS Errors | net.errorFcs.delta.summation.number | Number of frames transmitted or received with a bad checksum (CRC value) in the Ethernet frame.<br>Frame check sequence errors indicate the frames of data corrupted during transmission. These frames are dropped and not propagated to other ports. |
| Giant Errors | net.errorGiants.delta.summation.number | Number of giant errors over the network during the selected duration. |
| Interface Rx Utilization (%) | net.rx.utilization.absolute.latest.percent | Interface utilization percentage for the received traffic. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Interface Tx Utilization (%) | net.tx.utilization.absolute.latest.percent | Interface utilization percentage for the transmitted traffic. |
| Interface Utilization (%) | net.utilization.absolute.latest.percent | Interface utilization percentage for received and transmitted traffic. |
| Max Network Traffic Rate (kbps) | net.usage.rate.maximum.kiloBitsPerSecond | Maximum network usage rate over any five minute interval in the selected duration. |
| Max Network Tx Rate (kbps) | net.transmitted.rate.maximum.kiloBitsPerSecond | Maximum network data transmit rate over any five minute interval in the selected duration. |
| Max Packet Drop Ratio (%) | net.packetDrop.ratio.maximum.percent | Maximum five minute interval ratio of total dropped packets to total number packets. |
| Max Packet Drops | net.droppedTotal.delta.maximum.number | Maximum number of dropped Rx and Tx packets over any five minute interval in the selected duration. |
| Multicast Rx Packets | net.multicastRx.delta.summation.number | Number of multicast packets received in the selected duration. |
| Multicast Tx Packets | net.multicastTx.delta.summation.number | Number of multicast packets transmitted in the selected duration. |
| Network Align Errors | net.errorAlign.delta.summation.number | Number of alignment errors detected over the network in the selected duration.<br>Network alignment errors occur if a frame arrives with part of an octet missing, and having an FCS error. |
| Network Carrier Sense Errors | net.errorCarrierSense.delta.summation.number | Number of carrier sense errors detected over the network in the selected duration.<br>Network carrier sense errors occur when an interface cannot transmit a frame because it did not detect a carrier. |
| Network Deferred Tx Errors | net.errorDeferredTx.delta.summation.number | Number of deferred transmission errors detected over the network in the selected duration. |
| Network Excessive Collision Errors | net.errorExcessiveCollisions.delta.summation.number | Number of excessive collision errors detected over the network in the selected duration.<br>Network excessive collision error occurs when a station receives 16 consecutive collisions while attempting to transmit a single frame. In such situations, the frame is dropped due to the excessive collisions. |
| Network Late Collision Errors | net.errorLateCollisions.delta.summation.number | Number of late collision errors detected over the network in the selected duration. |
| Network Long Frame Errors | net.errorFrameTooLongs.delta.summation.number | Number of network long frame errors detected over the network in the selected duration. |
| Network Max Rx Rate | net.received.rate.maximum.kiloBitsPerSecond | Maximum rate at which the data is received during the time interval. |
| Network Multi Collision Errors | net.errorMultiCollisionFrames.delta.summation.number | Number of multi collision errors detected over the network in the selected duration. |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of packets transmitted and received during the time interval. |
| Network Packet Drop Percent | net.packetDrop.ratio.average.percent | Average ratio of total number of dropped packets to total number of packets. |
| Network Packet Drops | net.droppedTotal.delta.summation.number | Total number of packets dropped during the time interval. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Network Receive Errors | net.errorRcv.delta.summation.number | Number of receive errors received on the physical interface in the selected duration.<br>Receive errors occur when there is excessive output rates of traffic, or if the receive buffer is full. |
| Network Rx Int Mac Errors | net.errorRxIntMac.delta.summation.number | Number of frames for which reception on a particular interface has failed due to an internal MAC sublayer receive error. |
| Network Rx Rate | net.received.rate.average.kiloBitsPerSecond | Average rate at which data is received during the time interval. |
| Network Single Collision Errors | net.errorSingleCollisionFrames.delta.summation.number | Number of single collision errors detected over the network in the selected duration. |
| Network SQE Test Errors | net.errorSQETests.delta.summation.number | Number of signal quality test errors detected over the network in the selected duration. |
| Network Symbol Errors | net.errorSymbol.delta.summation.number | Number of symbol errors detected over the network in the selected duration. |
| Network Traffic Rate | net.usage.rate.average.kiloBitsPerSecond | Average rate of received and transmitted traffic during the time interval. |
| Network Tx Intmac Errors | net.errorTxIntMac.delta.summation.number | Number of frames for which transmission on a particular interface fails due to an internal MAC sublayer transmit error. |
| Network Tx Rate | net.transmitted.rate.average.kiloBitsPerSecond | Average rate of transmitted traffic during the time interval. |
| Network Undersize Errors | net.errorUnderSize.delta.summation.number | Number of undersize errors detected over the network in the selected duration.<br>This error indicates a bad frame generated by the connected device. |
| Network Xmit Errors | net.errorXmit.delta.summation.number | Number of Xmit errors detected over the network in the selected duration.<br>Xmit errors occur when there is excess input rates of traffic, or if the transmit buffer is full.<br>Increase speed and move the link partner to full-duplex to minimize the occurance of this error. |
| Out Queue Length | net.outQLen.absolute.average.number | Number of output packets waiting in the queue. |
| Rx Broadcast Packets | net.broadcastRx.delta.summation.number | Number of broadcast packets received during the time interval. |
| Rx Broadcast Ratio (%) | net.broadcastByRx.ratio.average.percent | Percentage of broadcast packets received during the time interval. |
| Rx Jumbo Packets | net.jumboRx.delta.summation.number | Number of jumbo packets received during the time interval. |
| Rx Packet Drop Percent (%) | net.packetDropRx.ratio.average.percent | Average ratio of total number of dropped Rx packets to total number of Rx packets. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Rx Packet Errors | net.errorRx.delta.summation.number | Number of received packet errors detected over the network in the selected duration.<br>For packet-oriented interfaces, Rx packet error indicates the number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol.<br>For character-oriented or fixed-length interfaces, Rx packet error indicates the number of inbound transmission units that contained errors preventing them from being deliverable to a higher-layer protocol. |
| Rx Packets | net.packetsRx.delta.summation.number | Number of packets received during the interval. |
| Total Network Traffic | net.usage.delta.summation.kiloBytes | Sum of data transmitted and received during the time interval. |
| Tx Broadcast Packets | net.broadcastTx.delta.summation.number | Number of broadcast packets transmitted during a specified time interval. |
| Tx Broadcast Ratio | net.broadcastByTx.ratio.average.percent | Average percent of broadcast packets transmitted during a specified time interval. |
| Tx Jumbo Packets | net.jumboTx.delta.summation.number | Number of jumbo packets transmitted during the time interval. |
| Tx Packet Drop Percent | net.packetDropTx.ratio.average.percent | Ratio of total number of dropped Tx packets to total number of Tx packets. |
| Tx Packet Errors | net.errorTx.delta.summation.number | Number of transmitted packet errors detected over the network in the selected duration.<br>For packet-oriented interfaces, Tx packet errors indicate the number of outbound packets that were not transmitted because of errors.<br>For character-oriented or fixed-length interfaces, Tx packet errors indicate the number of outbound transmission units that were not transmitted because of errors. |
| Tx Packets | net.packetsTx.delta.summation.number | Number of packets transmitted during the time interval. |
| Unicast Rx Packets | net.unicastRx.delta.summation.number | Total number of unicast packets received during the time interval. |
| Unicast Tx Packets | net.unicastTx.delta.summation.number | Total number of unicast packets transmitted during the time interval. |
| Unknown Rx Packets | net.unknownRx.delta.summation.number | Total number of unknown packets received during the time interval.<br>For packet-oriented interfaces, unknown Rx packets indicate the number of packets received through the interface that were discarded because of an unknown protocol or an unsupported protocol.<br>For character-oriented or fixed-length interfaces that support protocol multiplexing, unknown Rx packets indicate the number of transmission units received through the interface that were discarded because of an unknown protocol or an unsupported protocol. |

## NetFlow Reporter Metrics

NetFlow reporter metrics provide information about the flow records dropped at the VCF Operations for networks collector.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Outbound expire flow drop count | flow.fiveTupleExpireOutbound.delta.summation.number | Number of five tuples dropped due to outbound limit hit for Source IP addresses in Flows. |
| Wrong collector flow drop count | flow.rawRecordReporterWrongCollector.delta.summation.number | Number of raw flow records dropped as these were reported on the wrong type of VCF Operations for networks collector. |

## Metrics for NSX-T Entities

When you add a VMware NSX Manager as a datasource, VCF Operations for networks collects metrics from NSX entities that are associated with the deployment to troubleshoot problems in your environment.

### Metrics for NSX-T Firewall Rule

NSX firewall rules is a set of customizable rules that protect the system against network threats.

The following metrics provide information about the traffic processed by NSX firewall rules:

| Metric Name | Metric API Name | Description |
|---|---|---|
| Flow Packets | net.packet.delta.summation.number | Number of packets processed by the NSX firewall rule. |
| Hit Count | net.hit.delta.summation.number | Number of hits received by the NSX firewall rule. |
| Session Count | net.connection.delta.summation.number | Number of sessions processed by the NSX firewall rule. |
| Total Bytes | net.byte.delta.summation.number | Number of bytes processed by the NSX firewall rule. |

### Metrics for NSX-T Edge Node

NSX edge node metrics provide information about the usage of NSX Edge nodes.

Starting VCF 9.1, NSX-T Edge monitoring metrics are not available on the VCF Operations for networks UI. The metrics are available on the NSX-T Edge dashboards in **Operate** > **VCF Health** in VCF Operations. For more information, see NSX Health in VCF Operations Health and Diagnostics.

**Table 1346: General Metrics**

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Admin State | adminState | 5 minutes | Administrative state of the edge cluster, which can be one of the following: Up, Down |
| BFD Tunnel Down Count | net.bfd.tunnel.down.count.absolute.latest.number | 5 minutes | Total number of Bidirectional Forwarding Detection (BFD) tunnels in down state. |
| BFD Tunnel Up Count | net.bfd.tunnel.up.count.absolute.latest.number | 5 minutes | Total number of Bidirectional Forwarding Detection (BFD) tunnels in Up state. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Controller Connectivity | controlConnectionStatus | 5 minutes | Status of the control connection between edge node and controller node, which can be one of the following: Up, Down |
| CPU Cores | nCPUs | 5 minutes | The number of CPU cores in the edge node. |
| CPU Usage | sys.loadFifteenMinutes.rate.latest.percent | 5 minutes | Percentage of CPU usage in the edge node. |
| DataPath IPC Thread Status | edgeDPThreadStatus | 5 minutes | The datapath thread status, which can be one of the following: Healthy, Unhealthy |
| Disk Used | disk.node.usage.absolute.latest.kiloBytes | 5 minutes | Kilobytes of disk space used across all partitions. |
| DP Memory Usage Rate | mem.edgeDP.usage.absolute.average.percent | 20 seconds | Percentage of RAM used by the edge datapath. |
| Edge Agent Status | edgeAgentStatus | 5 minutes | Status of the Edge Agent, which can be one of the following: Up, Down |
| Edge OPS Agent Status | nsxOpsAgentStatus | 5 minutes | Status of the Ops Agent, which can be one of the following: Up, Down |
| Fifteen Minute Load Average | sys.loadFifteenMinutes.absolute.maximum.number | 20 seconds | The average system load over the past 15 minutes, as returned by the getloadavg() API method. System load is defined as the number of processes in the system run queue. |
| Five Minute Load Average | sys.loadFiveMinutes.absolute.maximum.number | 20 seconds | The average system load over the past 5 minutes, as returned by the getloadavg() API method. System load is defined as the number of processes in the system run queue. |
| HA State | nodeRole | 5 minutes | The High Availability (HA) state of the edge node in the edge cluster, which can be one of the following: Disabled, Offline, Discover, StateSync, Inactive, Active. "Active" represents the healthy state. |
| Maintenance Mode | maintenanceMode | 5 minutes | Status of the edge maintenance mode. |
| Management Connection Status | mgmtConnectionStatus | 5 minutes | Status of the management connection, which can be one of the following: Up, Down |
| Memory Cache | mem.cache.absolute.latest.kiloBytes | 20 seconds | Number of bytes used by the edge memory cache. |
| Memory Usage | mem.usage.absolute.latest.kiloBytes | 20 seconds | Total amount of usable RAM in bytes, defined as physical RAM minus a number of reserved bits and the kernel binary code. |
| Memory Usage Rate | mem.usage.absolute.average.percent | 20 seconds | Percentage of memory in use over total memory, per process. |
| One Minute Load Average | sys.loadOneMinute.absolute.maximum.number | 20 seconds | The average system load over the past 1 minute, as returned by the getloadavg() API method. System load is defined as the number of processes in the system run queue. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| PNIC / Bond Status | pnicStatus | 5 minutes | The pNIC status, which can be one of the following: Up, Down, Degraded, Unknown |
| PNIC Down Count | net.pnic.down.count.absolute.latest.number | 5 minutes | The pNIC down count. |
| PNIC Up Count | net.pnic.up.count.absolute.latest.number | 5 minutes | The number of physical NICs (pNICs) that are up. |
| Service Status | serviceStatus | 5 minutes | Collection of the following statuses: Datapath Config Channel, Datapath Status Channel, Routing Status Channel, Routing Status |
| Status | overallStatus | 5 minutes | The roll-up status of the pNIC, management connection, control connection, tunnel, and agent statuses, which can be one of the following: Up, Down, Degraded, Unknown |
| Swap Memory Usage | mem.swapused.absolute.latest.kiloBytes | 20 seconds | The amount of swap memory in use. |
| System Uptime | sys.uptime.absolute.latest.millisecond | 5 minutes | Number of milliseconds that a system has been running continuously without interruption or reboot. |
| Tier0 Routing Status | tier0RoutingStatus | 5 minutes | The overall routing status. |
| Total Disk Space | totalDiskSpace | 5 minutes | The total disk space for all partitions allocated by the edge node. |
| Total Memory | totalMemory | 20 seconds | Total amount of RAM used. |
| Total Swap | totalSwapMemory | 20 seconds | The total size of swap memory. |
| Tunnel Status | tunnelStatus | 5 minutes | The tunnel status, which can be one of the following: Up, Down, Degraded, Unknown |
| VTEP State | vtepState | 5 minutes | The VTEP state of the edge cluster, which can be one of the following: Up, Down |

**Table 1347: GPU Core Metrics**

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Core CPU Usage | net.edge.service.cpuCore.usage.rate.average.percent | 5 minutes | The percentage of time spent by all processes, per non-dataplane service core. |
| Edge Dataplane CPU Core Mega Flow Cache Hit Rate Percent | edge.dataplane.cpu.core.megaflowcache.hit.rate.average.percent | 5 minutes | Percentage of hits in the mega flow cache, per datapath CPU core. |
| Edge Dataplane CPU Core Micro Flow Cache Hit Rate Percent | edge.dataplane.cpu.core.microflowcache.hit.rate.average.percent | 5 minutes | Percentage of hits in the micro flow cache, per datapath CPU core. |
| Edge Dataplane CPU Core Usage Rate (%) | edge.dataplane.cpu.core.usage.rate.average.percent | 20 seconds | Percentage of utilized cycles per datapath CPU core. |
| Edge Dataplane CPU Core Usage Rate Rx | edge.dataplane.cpu.core.ppsRx.usage.rate.average.number | 5 minutes | Number of datapath-received packets per second, per datapath CPU core. |
| Edge Dataplane CPU Core Usage Rate Tx | edge.dataplane.cpu.core.ppsTx.usage.rate.average.number | 5 minutes | Number of datapath-transmitted packets per second, per datapath CPU core. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Mega Flow Cache Entry Added Count | net.edgeDP.cpuCore.megaflowCache.insertions.absolute.average.number | 5 minutes | Average number of new entires added to the mega flow cache, per datapath CPU core. |
| Mega Flow Cache Hits | net.edgeDP.cpuCore.megaflowCache.hit.absolute.average.number | 5 minutes | Number of packets forwarded through the mega flow cache, per datapath CPU core. |
| Mega Flow Cache Max Entries Seen | net.edgeDP.cpuCore.megaflowCache.maxSeen.rate.average.percent | 5 minutes | Percentage of maximum number of entries seen in the mega flow cache, per datapath CPU core. |
| Mega Flow Cache Missed Packets | net.edgeDP.cpuCore.megaflowCache.dont.cache.absolute.latest.number | 5 minutes | Number of packets that cannot be cached in the mega flow cache, per datapath CPU core. |
| Mega Flow Cache Packets Passed to Next Layer | net.edgeDP.cpuCore.megaflowCache.missed.absolute.maximum.number | 5 minutes | Maximum number of packets passed to the next layer due to cache miss in the mega flow cache, per datapath CPU core. |
| Mega Flow Cache Skipped Packets | net.edgeDP.cpuCore.megaflowCache.skipped.absolute.latest.number | 5 minutes | Number of packets skipped by mega flow cache due to unsupported type or disabled cache, per datapath CPU core. |
| Micro Flow Cache Entry added Count | net.edgeDP.cpuCore.microflowCache.insertions.absolute.average.number | 5 minutes | Average number of new entries added to the micro flow cache, per datapath CPU core. |
| Micro Flow Cache Hits | net.edgeDP.cpuCore.microflowCache.hit.absolute.average.number | 5 minutes | Number of packets forwarded through the micro flow cache, per datapath CPU core. |
| Micro Flow Cache Max Entries Seen | net.edgeDP.cpuCore.microflowCache.maxSeen.rate.average.percent | 5 minutes | Percentage of max entries seen in the micro flow cache, per datapath CPU core. |
| Micro Flow Cache Missed Packets | net.edgeDP.cpuCore.microflowCache.dont.cache.absolute.latest.number | 5 minutes | Number of packets that cannot be cached in the micro flow cache, per datapath CPU core. |
| Micro Flow Cache Packets Passed to Next Layer | net.edgeDP.cpuCore.microflowCache.missed.absolute.maximum.number | 5 minutes | Number of packets passed to the next layer due to cache miss in the micro flow cache, per datapath CPU core. |
| Micro Flow Cache Skipped Packets | net.edgeDP.cpuCore.microflowCache.skipped.absolute.latest.number | 5 minutes | Number of packets skipped due to unsupported type or disabled cache, per datapath CPU core. |
| Packets Processed | net.edgeDP.cpuCore.packetsProcessedPerCore.absolute.latest.number | 5 minutes | Number of packets processed per second, per datapath CPU core, from NICs, KNIs, and other cores. |
| Packets Queued Per Port Per Queue | net.edgeDP.cpuCore.packetsPerPortPerQueue.absolute.latest.number | 5 minutes | Number of packets queued per datapath CPU core, per port, per queue. |

### Table 1348: Edge File System Metrics and Memory Pool Metrics

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Disk Available Percentage | disk.available.rate.latest.percent | 5 minutes | Percentage of total disk space on the edge node that is currently unused and available for storage. |
| Disk Read Time | disk.read.wait.time.absolute.average.millisecond | 5 minutes | The average time in milliseconds that read requests wait on the block device per partition. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Disk Write Time | disk.write.wait.time.absolute.average.millisecond | 5 minutes | The average time in milliseconds that write requests wait on the block device per partition. |
| IO Mode | fileSystemsIOMode | 5 minutes | Storage mode per partition. Possible storage modes are read, write, or both read/write. |
| Used | disk.usage.absolute.latest.kiloBytes | 5 minutes | Total kilobytes used by file system, per partition. |
| Datapath Memory Pool Usage Percent | mem.pool.usage.absolute.latest.percent | 20 seconds | Percentage of memory allocated to the datapath that is currently being used to store and process network packets. |

**Table 1349: Management Kernel Metrics**

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Dropped Rx Packets | net.droppedRx.delta.summation.number | 5 minutes | Number of received packets dropped during the sampling interval. |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped during the sampling interval. |
| Rx Packet Drop Rate | net.packetDropReceived.ratio.average.percent | 5 minutes | Average ratio of dropped received packets to total received packets. |
| Rx Packet Errors | net.errorRx.delta.summation.number | 5 minutes | For packet-oriented interfaces, the number of inbound packets that contained errors preventing their delivery to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors preventing them from delivery to a higher-layer protocol. |
| Rx Packet Per Second | net.ppsRx.rate.average.number | 5 minutes | Average rate of packets received per second. |
| Rx Packets | net.packetsRx.delta.summation.number | 5 minutes | Number of packets received during the sampling interval. |
| Total Packet Per Second | net.ppsTotal.rate.average.number | 5 minutes | Average rate of total packets (received + transmitted) per second. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | 5 minutes | Total number of received bytes. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | 5 minutes | Total number of transmitted bytes. |
| Tx Packet Drop Rate | net.packetDropTransmitted.ratio.average.percent | 5 minutes | Average ratio of dropped transmitted packets to total transmitted packets. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Tx Packet Errors | net.errorTx.delta.summation.number | 5 minutes | For packet-oriented interfaces, the number of outbound packets that could not be transmitted due to errors. For character-oriented or fixed-length interfaces, the number of outbound transmission units that could not be transmitted due to errors. |
| Tx Packet Per Second | net.ppsTx.rate.average.number | 5 minutes | Average rate of packets transmitted per second. |
| Tx Packets | net.packetsTx.delta.summation.number | 5 minutes | Number of packets transmitted by all the virtual network interface controllers (vNICs) of the VM during the sampling interval. |

**Table 1350: Node Process Metrics**

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| CPU Usage Rate | cpu.usage.rate.average.percent | 20 seconds | Percentage of process CPU time over total system CPU time. The percentage could exceed 100 when you have multiple CPU cores. This metric is collected per process. |
| Memory Usage Rate | mem.usage.absolute.average.percent | 20 seconds | Percentage of memory in use over total memory, per process. |

**Table 1351: Physical Interface Metrics**

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Dropped Tx Packets | net.droppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped during the sampling interval on the physical interface. |
| Lookup Failure Rx Drop PPS | net.lookUpFailureRx.delta.summation.number | 5 minutes | Number of received packet drops per second due to lookup failures on the datapath physical interface. |
| MBUF Packet Alloc Failures | net.rxNoMbuf.delta.summation.number | 5 minutes | The number of received packet drops per second on the atapath physical interface caused by Memory Buffer (MBUF) allocation failures. |
| Rx Misses | net.rxMisses.delta.summation.number | 5 minutes | Total number of received packet misses during the sampling interval, per datapath physical interface. This metric is available only for NSX Edge transport node interfaces. |
| Rx Packet Drop Rate | net.packetDropReceived.ratio.average.percent | 5 minutes | Average ratio of dropped received packets to total received packets. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Rx Packet Errors | net.errorRx.delta.summation.number | 5 minutes | For packet-oriented interfaces, the number of inbound packets that contained errors preventing their delivery to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors preventing them from delivery to a higher-layer protocol. |
| Rx Packet Per Second | net.ppsRx.rate.average.number | 5 minutes | Average rate of packets received per second. |
| Rx Packets | net.packetsRx.delta.summation.number | 5 minutes | Number of packets received through the physical interface during the sampling interval. |
| Throughput | net.nicThroughput.delta.summation.number | 5 minutes | NIC throughtput (rx+tx) per datapath physical interface. |
| Total Packet Per Second | net.ppsTotal.rate.average.number | 5 minutes | Average rate of total packets (received + transmitted) per second. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | 5 minutes | Total number of received bytes on the physical interface. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | 5 minutes | Total number of transmitted bytes through the physical interface. |
| Tx Packet Drop Rate | net.packetDropTransmitted.ratio.average.percent | 5 minutes | Average ratio of dropped transmitted packets to total transmitted packets. |
| Tx Packet Errors | net.errorTx.delta.summation.number | 5 minutes | For packet-oriented interfaces, the number of outbound packets that could not be transmitted due to errors. For character-oriented or fixed-length interfaces, the number of outbound transmission units that could not be transmitted due to errors. |
| Tx Packet Per Second | net.ppsTx.rate.average.number | 5 minutes | Average rate of packets transmitted per second. |
| Tx Packets | net.packetsTx.delta.summation.number | 5 minutes | Number of packets transmitted through the physical interface during the sampling interval. |

**Table 1352: Service Router Metrics**

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| BGP Neighbour Down Count | net.bgp.neighbor.down.count.absolute.latest.number | 5 minutes | Number of Border Gateway Protocol (BGP) neighbors identified as Down. |
| BGP Neighbour Up Count | net.bgp.neighbor.up.count.absolute.latest.number | 5 minutes | Number of Border Gateway Protocol (BGP) neighbors identified as Up. |
| OSPF Neighbor Down Count | net.ospf.neighbor.down.count.absolute.latest.number | 5 minutes | Number of Open Shortest Path First (OSPF) neighbors identified as Down. |
| OSPF Neighbor Up Count | net.ospf.neighbor.up.count.absolute.latest.number | 5 minutes | Number of Open Shortest Path First (OSPF) neighbors identified as Up. |

**Table 1353: Uplink Router Metrics**

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| ARP Absence Dropped Rx Packets | net.noARPDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped due to the absence of ARP on the Tier-0 uplink. |
| ARP Absence Dropped Tx Packets | net.noARPDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped due to absence of ARP on the Tier-0 uplink. |
| Blocked Rx Packets | net.blockedRx.delta.summation.number | 5 minutes | Number of blocked received packets due to a standby interface, on the Tier-0 uplink. |
| Blocked Tx Packets | net.blockedTx.delta.summation.number | 5 minutes | Number of transmitted packets blocked by standby interface, on the Tier-0 uplink. |
| Destination Unsupported Dropped Rx Packets | net.destUnsupportedDroppedRx.delta.summation.number | 5 minutes | Number of packets dropped on the Tier-0 uplink, due to an unsupported destination such as multicast/loopback/ reserved address. |
| Destination Unsupported Dropped Tx Packets | net.destUnsupportedDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink, because destination is not supported. |
| Dropped Rx Packets | net.droppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink during the sampling interval. |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink during the sampling interval. |
| Duplicate Address Detected Dropped Rx Packets | net.dadDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to duplicate IP detection. |
| Duplicate Address Detected Dropped Tx Packets | net.dadDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to duplicate IP detection. |
| Firewall Dropped Rx Packets | net.firewallDroppedRx.delta.summation.number | 5 minutes | Number of received packet drops on the Tier-0 uplink due to firewall. |
| Firewall Dropped Tx Packets | net.firewallDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packet drops on the Tier-0 uplink due to firewall. |
| Fragmentation Dropped Rx Packets | net.fragNeededDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to a need for fragmentation. |
| Fragmentation Dropped Tx Packets | net.fragNeededDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to a need for fragmentation. |
| Insufficient Memory Dropped Rx Packets | net.noMemoryDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to insufficient memory. |
| Insufficient Memory Dropped Tx Packets | net.noMemoryDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to insufficient memory. |
| IPSec Dropped Rx Packets | net.IPsecDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped by IPsec input on the Tier-0 uplink. |
| IPSec Dropped Tx Packets | net.IPsecDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped by IPsec input on the Tier-0 uplink. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| IPSec Policy Block Dropped Rx Packets | net.IPsecPolicyBlockDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to blocking by IPsec policy. |
| IPSec Policy Block Dropped Tx Packets | net.IPsecPolicyBlockDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to blocking by IPsec policy. |
| IPSec Policy Error Dropped Rx Packets | net.IPsecPolicyErrorDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to IPsec policy error. |
| IPSec Policy Error Dropped Tx Packets | net.IPsecPolicyErrorDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to IPsec policy error. |
| IPSec Security Association Absence Dropped Rx Packets | net.IPsecNoSaDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink by IPsec missing a Security Association (SA). |
| IPSec Security Association Absence Dropped Tx Packets | net.IPsecNoSaDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink by IPsec missing a Security Association (SA). |
| IPSec VTI Absence Dropped Rx Packets | net.IPsecNoVtiDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink by IPsec input missing a Virtual Tunnel Interface (VTI). |
| IPSec VTI Absence Dropped Tx Packets | net.IPsecNoVtiDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink by IPsec input missing a Virtual Tunnel Interface (VTI). |
| IPV6 Dropped Rx Packets | net.IPV6DroppedRx.delta.summation.number | 5 minutes | Number of received IPv6 packet drops on the Tier-0 uplink. |
| IPV6 Dropped Tx Packets | net.IPV6DroppedTx.delta.summation.number | 5 minutes | Number of transmitted IPv6 packet drops on the Tier-0 uplink. |
| Kernel Nic Interface Dropped Rx Packets | net.KNIDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink by the DPDK kernel NIC interface. |
| Kernel Nic Interface Dropped Tx Packets | net.KNIDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink by the DPDK kernel NIC interface. |
| Linked Port Absence Dropped Rx Packets | net.noLinkedDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to the absence of a linked port. |
| Linked Port Absence Dropped Tx Packets | net.noLinkedDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to the absence of a linked port. |
| Malformed Dropped Rx Packets | net.malformedDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to malformed packet. |
| Malformed Dropped Tx Packets | net.malformedDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to malformed packet. |
| Non IP Dropped Rx Packets | net.nonIPDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink because interface allows only IP packets. |
| Non IP Dropped Tx Packets | net.nonIPDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink because interface allows only IP packets. |

| Metric Display Name | Metric API Name | Export Frequency | Description |
|---|---|---|---|
| Receiver Absence Dropped Rx Packets | net.noReceiverDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to absence of receiver. |
| Receiver Absence Dropped Tx Packets | net.noReceiverDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to absence of receiver. |
| Redirect Dropped Rx Packets | net.redirectDroppedRx.delta.summation.number | 5 minutes | Number of redirect RX packets dropped. |
| Redirect Dropped Tx Packets | net.redirectDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped due to exceeded time to live. |
| Route Absence Dropped Rx Packets | net.noRouteDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink, due to the absence of a route. |
| Route Absence Dropped Tx Packets | net.noRouteDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink, due to the absence of a route. |
| Rx Packets | net.packetsRx.delta.summation.number | 5 minutes | Number of packets received through the Tier-0 uplink during the sampling interval. |
| Service Insert Dropped Rx Packets | net.serviceInsertDroppedRx.delta.summation.number | 5 minutes | Number of service insert RX packets dropped on the Tier-0 uplink. |
| Service Insert Dropped Tx Packets | net.serviceInsertDroppedTx.delta.summation.number | 5 minutes | Number of service insert TX packets dropped on the Tier-0 uplink. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | 5 minutes | Total number of bytes received through the Tier-0 uplink. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | 5 minutes | Total number of bytes transmitted through the Tier-0 uplink. |
| TTL Exceeded Dropped Rx Packets | net.ttlExceededDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to exceeded time to live (TTL). |
| TTL Exceeded Dropped Tx Packets | net.ttlExceededDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to exceeded time to live (TTL). |
| Tx Packets | net.packetsTx.delta.summation.number | 5 minutes | Number of packets transmitted through the Tier-0 uplink during the sampling interval. |
| Unsupported L4 Port Dropped Rx Packets | net.L4PortUnsupportedDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped on the Tier-0 uplink due to an unsupported L4 port. |
| Unsupported L4 Port Dropped Tx Packets | net.L4PortUnsupportedDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped on the Tier-0 uplink due to an unsupported L4 port. |
| Unsupported Protocol Dropped Rx Packets | net.protoUnsupportedDroppedRx.delta.summation.number | 5 minutes | Number of received packets dropped due to unsupported protocol. |
| Unsupported Protocol Dropped Tx Packets | net.protoUnsupportedDroppedTx.delta.summation.number | 5 minutes | Number of transmitted packets dropped due to an unsupported protocol. |
| uRPF Drop Packets | net.droppedRPFRx.delta.summation.number | 5 minutes | Number of packets dropped on the Tier-0 uplink due to violations of the Unicast Reverse Path Forwarding (uRPF) security mechanism. |

### Metrics for NSX-T Manager

VCF Operations for networks collects flow metrics for NSX manager.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Outbound Expire Flow Drop Count | flow.fiveTupleExpireOutbound.delta.summation.number | Number of five tuples dropped because of reaching the maximum outbound limit for source IP addresses in flows. |
| Wrong Collector Flow Drop Count | flow.rawRecordReporterWrongCollector.delta.summation.number | Number of raw flow records dropped as the flow records were reported on a wrong type of VCF Operations for networks collector. |

### Metrics for NSX-T Management Node

VCF Operations for networks collects NSX management node metrics to monitor the performance of NSX management nodes and troubleshoot issues, if any.

| Metric Name | Metric API Name | Description |
|---|---|---|
| CPU Usage (%) | sys.loadFifteenMinutes.rate.latest.percent | Percentage of CPU used out of its total capacity in the time interval. |
| Fifteen Minute Load Average | sys.loadFifteenMinutes.absolute.maximum.number | Average system load over an interval of fifteen minutes. |
| Five Minute Load Average | sys.loadFiveMinutes.absolute.maximum.number | Average system load over a period of five minutes. |
| Memory Cache | mem.cache.absolute.latest.kiloBytes | Total memory used by the system for disk caching in the time interval. |
| Memory Usage | mem.usage.absolute.latest.kiloBytes | Total amount of memory used by the system, including swap memory, in the time interval. |
| Memory Usage Rate (%) | mem.usage.absolute.latest.percent | Average percentage of the memory used, including swap memory, out of the total available memory. |
| One Minute Load Average | sys.loadOneMinute.absolute.maximum.number | Average system load in a minute. |
| Swap Memory Usage | mem.swapused.absolute.latest.kiloBytes | Amount of swap memory used by the system in the time interval. |
| System Uptime (ms) | sys.uptime.absolute.latest.millisecond | Total time elapsed since the last system startup. |

### Metrics for NSX-T Logical Switch

NSX logical switch metrics provide information about the traffic processed by NSX logical switches.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Dropped Rx Packets | net.droppedRx.delta.summation.number | The number of received packets dropped to total received packets. |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | The number of transmitted packets dropped to total transmitted packets. |
| Multicast & Broadcast Rx Bytes | net.multicastBroadcastRx.delta.summation.bytes | Total number of received multicast & broadcast bytes. |
| Multicast & Broadcast Rx Packets | net.multicastBroadcastRx.delta.summation.number | Total number of received multicast & broadcast packets. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Multicast & Broadcast Tx Bytes | net.multicastBroadcastTx.delta.summation.bytes | Total number of transmitted multicast & broadcast bytes. |
| Multicast & Broadcast Tx Packets | net.multicastBroadcastTx.delta.summation.number | Total number of transmitted multicast & broadcast packets. |
| Rx Packet Drop Rate (%) | net.packetDropReceived.ratio.average.percent | Average ratio of received packets dropped to total received packets. |
| Rx Packets | net.packetsRx.delta.summation.number | Total number of received Packets during the time interval |
| Rx Unicast Packets | net.unicastPacketsRx.delta.summation.number | Average number of unicast packets received during the time interval. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | Sum of bytes received during the time interval. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | Sum of bytes transmitted during the time interval. |
| Tx Packet Drop Rate (%) | net.packetDropTransmitted.ratio.average.percent | Average ratio of transmitted packets dropped to total transmitted packets. |
| Tx Packets | net.packetsTx.delta.summation.number | Total number of packets transmitted during the time interval. |
| Tx Unicast Packets | net.unicastPacketsTx.delta.summation.number | Average number of unicast packets transmitted during the time interval. |
| Unicast Rx Bytes | net.unicastRx.delta.summation.bytes | Total volume of unicast packets received over the time interval, expressed in bytes. |
| Unicast Tx Bytes | net.unicastTx.delta.summation.bytes | Total volume of unicast packets transmitted over the time interval, expressed in bytes. |

### Metrics for NSX-T Logical Port

NSX logical port metrics provide information about the traffic processed by NSX logical ports.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Dropped Rx Packets | net.droppedRx.delta.summation.number | The number of received packets dropped to total received packets. |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | The number of transmitted packets dropped to total transmitted packets. |
| Interface Rx Utilization (%) | net.rx.utilization.absolute.latest.percent | Interface utilization percentage for the received traffic. |
| Interface Tx Utilization (%) | net.tx.utilization.absolute.latest.percent | Interface utilization percentage for the transmitted traffic. |
| Interface Utilization (%) | net.utilization.absolute.latest.percent | Average interface utilization percentage for received and transmitted traffic. |
| Multicast & Broadcast Rx Bytes | net.multicastBroadcastRx.delta.summation.bytes | Total number of received multicast & broadcast bytes. |
| Multicast & Broadcast Rx Packets | net.multicastBroadcastRx.delta.summation.number | Total number of received multicast & broadcast packets. |
| Multicast & Broadcast Tx Bytes | net.multicastBroadcastTx.delta.summation.bytes | Total number of transmitted multicast & broadcast bytes. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Multicast & Broadcast Tx Packets | net.multicastBroadcastTx.delta.summation.number | Total number of transmitted multicast & broadcast packets. |
| Rx Packet Drop Rate (%) | net.packetDropReceived.ratio.average.percent | Average ratio of received packets dropped to total received packets. |
| Rx Packets | net.packetsRx.delta.summation.number | Total number of received Packets during the time interval |
| Rx Unicast Packets | net.unicastPacketsRx.delta.summation.number | Average number of unicast packets received during the time interval. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | Sum of bytes received during the time interval. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | Sum of bytes transmitted during the time interval. |
| Tx Packet Drop Rate (%) | net.packetDropTransmitted.ratio.average.percent | Average ratio of transmitted packets dropped to total transmitted packets. |
| Tx Packets | net.packetsTx.delta.summation.number | Total number of packets transmitted during the time interval. |
| Tx Unicast Packets | net.unicastPacketsTx.delta.summation.number | Average number of unicast packets transmitted during the time interval. |
| Unicast Rx Bytes | net.unicastRx.delta.summation.bytes | Total volume of unicast packets received over the time interval, expressed in bytes. |
| Unicast Tx Bytes | net.unicastTx.delta.summation.bytes | Total volume of unicast packets transmitted over the time interval, expressed in bytes. |

**Metrics for NSX-T Transport Node**

VCF Operations for networks collects NSX transport node metrics to monitor the performance of NSX transport nodes and troubleshoot issues, if any.

**NAT Metrics**

NAT metrics provide information about the total traffic consumed by the service router for the NAT (Network Address Translation) rules configured on the NSX transport node.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Flow Packet Count | flow.totalPackets.delta.summation.number | Sum of packets processed by all the NAT rules from all logical routers which are present on the transport node. |
| Session Count | net.connection.delta.summation.number | Sum of connections of all NAT rules from all logical routers which are present on the transport node. |
| Total Traffic | flow.totalBytes.delta.summation.bytes | Sum of bytes of all NAT rules from all logical routers which are present on the transport node. |

## Node Metrics

Node metrics provide information about the CPU usage and the system load of the NSX transport node.

| Metric Name | Metric API Name | Description |
|---|---|---|
| CPU Usage (%) | sys.loadFifteenMinutes.rate.latest.percent | Percentage of CPU used out of its total capacity in the time interval. |
| Fifteen Minute Load Average | sys.loadFifteenMinutes.absolute.maximum.number | Average system load over an interval of fifteen minutes. |
| Five Minute Load Average | sys.loadFiveMinutes.absolute.maximum.number | Average system load over a period of five minutes. |
| Memory Cache | mem.cache.absolute.latest.kiloBytes | Total memory used by the system for disk caching in the time interval. |
| Memory Usage | mem.usage.absolute.latest.kiloBytes | Total amount of memory used by the system, including swap memory, in the time interval. |
| Memory Usage Rate (%) | mem.usage.absolute.latest.percent | Average percentage of the memory used, including swap memory, out of the total available memory. |
| One Minute Load Average | sys.loadOneMinute.absolute.maximum.number | Average system load in a minute. |
| Swap Memory Usage | mem.swapused.absolute.latest.kiloBytes | Amount of swap memory used by the system in the time interval. |
| System Uptime (ms) | sys.uptime.absolute.latest.millisecond | Total time elapsed since the last system startup. |

### Metrics for NSX-T Edge NAT Rule

NSX Edge NAT rules metrics provide information about the traffic processed by NAT rules of NSX Edge devices.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Flow Packets | net.packet.delta.summation.number | Total number of flow packets processed by the NSX Edge NAT rule. |
| Session Count | net.connection.delta.summation.number | The total number of sessions handled by the NSX Edge NAT rule. |
| Total Bytes | net.byte.delta.summation.number | Total number of bytes processed by the NSX Edge NAT rule. |

### Metrics for NSX-T Router

VCF Operations for networks collects NSX router metrics to monitor the NAT (Network Address Translation) rules configured on the router.

| Metric Name | Metric API Name | DesMetrics for NSX-T Logical Portcription |
|---|---|---|
| Flow Packets | net.packet.delta.summation.number | Sum of packets of all the NAT rules which are present on the logical router. |
| Session Count | net.connection.delta.summation.number | Sum of connections of all the NAT rules which are present on the logical router. |
| Total Bytes | net.byte.delta.summation.number | Sum of bytes of all the NAT rules which are present on the logical router. |

## Router Interface Metrics

The router interface metrics provide information about the network performance of the router interface.

| Metric Name | Metric API Name | Description |
|---|---|---|
| Discarded Rx Packets | net.discardedRx.delta.summation.number | Number of discarded inbound packets. |
| Discarded Tx Packets | net.discardedTx.delta.summation.number | Number of discarded outbound packets. |
| Dropped Rx Packets | net.droppedRx.delta.summation.number | Number of received packets that were dropped during the collection interval. |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | Number of transmitted packets that were dropped during the collection interval. |
| FCS Errors | net.errorFcs.delta.summation.number | Number of frames transmitted or received with a bad checksum (CRC value) in the Ethernet frame.<br>Frame check sequence errors indicate the frames of data corrupted during transmission. These frames are dropped and not propagated to other ports. |
| Giant Errors | net.errorGiants.delta.summation.number | Number of giant errors (errors caused by packet having size greater than MTU of the interface) over the network during the selected duration. |
| Interface Rx Utilization (%) | net.rx.utilization.absolute.latest.percent | Interface utilization percentage for the received traffic. |
| Interface Tx Utilization (%) | net.tx.utilization.absolute.latest.percent | Interface utilization percentage for the transmitted traffic. |
| Interface Utilization (%) | net.utilization.absolute.latest.percent | Interface utilization percentage for received and transmitted traffic. |
| Max Network Traffic Rate (kbps) | net.usage.rate.maximum.kiloBytesPerSecond | Maximum network usage rate over any five minute interval in the selected duration. |
| Max Network Tx Rate (kbps) | net.transmitted.rate.maximum.kiloBytesPerSecond | Maximum network data transmit rate over any five minute interval in the selected duration. |
| Max Packet Drop Ratio (%) | net.packetDrop.ratio.maximum.percent | Maximum five minute interval ratio of total dropped packets to total number of packets. |
| Max Packet Drops | net.droppedTotal.delta.maximum.number | Maximum number of dropped Rx and Tx packets over any five minute interval in the selected duration. |
| Multicast Rx Packets | net.multicastRx.delta.summation.number | Number of multicast packets received in the selected duration. |
| Multicast Tx Packets | net.multicastTx.delta.summation.number | Number of multicast packets transmitted in the selected duration. |
| Network Align Errors | net.errorAlign.delta.summation.number | Number of alignment errors detected over the network in the selected duration.<br>Network alignment errors occur if a frame arrives with part of an octet missing, and has an FCS error. |
| Network Carrier Sense Errors | net.errorCarrierSense.delta.summation.number | Number of carrier sense errors detected over the network in the selected duration.<br>Network carrier sense errors occur when an interface cannot transmit a frame because it did not detect a carrier. |
| Network Deferred Tx Errors | net.errorDeferredTx.delta.summation.number | Number of deferred transmission errors detected over the network in the selected duration. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Network Excessive Collision Errors | net.errorExcessiveCollisions.delta.summation.number | Number of excessive collision errors detected over the network in the selected duration.<br>Network excessive collision errors occur when a station receives 16 consecutive collisions while attempting to transmit a single frame. In such a situation, the frame is dropped due to the excessive collisions. |
| Network Late Collision Errors | net.errorLateCollisions.delta.summation.number | Number of late collision errors detected over the network in the selected duration. |
| Network Long Frame Errors | net.errorFrameTooLongs.delta.summation.number | Number of network long frame errors detected over the network in the selected duration. |
| Network Max Rx Rate | net.received.rate.maximum.kiloBytesPerSecond | The maximum rate at which the data is received during the time interval. |
| Network Multi Collision Errors | net.errorMultiCollisionFrames.delta.summation.number | Number of multi collision errors detected over the network in the selected duration. |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of packets transmitted and received during the time interval. |
| Network Packet Drop Percent | net.packetDrop.ratio.average.percent | Average ratio of total number of dropped packets to total number of packets. |
| Network Packet Drops | net.droppedTotal.delta.summation.number | Total number of packets dropped during the time interval. |
| Network Receive Errors | net.errorRcv.delta.summation.number | Number of receive errors received on the physical interface in the selected duration.<br>Receive errors occur when there is excessive output rates of traffic, or if the receive buffer is full. |
| Network Rx Int Mac Errors | net.errorRxIntMac.delta.summation.number | Number of frames for which reception on a particular interface has failed due to an internal MAC sublayer receive error. |
| Network Rx Rate | net.received.rate.average.kiloBytesPerSecond | Average rate at which data is received during the time interval. |
| Network Single Collision Errors | net.errorSingleCollisionFrames.delta.summation.number | Number of single collision errors detected over the network in the selected duration. |
| Network SQE Test Errors | net.errorSQETests.delta.summation.number | Number of signal quality test errors detected over the network in the selected duration. |
| Network Symbol Errors | net.errorSymbol.delta.summation.number | Number of symbol errors detected over the network in the selected duration. |
| Network Traffic Rate | net.usage.rate.average.kiloBytesPerSecond | Average rate of received and transmitted traffic during the time interval. |
| Network Tx Intmac Errors | net.errorTxIntMac.delta.summation.number | Number of frames for which transmission on a particular interface failed due to an internal MAC sublayer transmit error. |
| Network Tx Rate | net.transmitted.rate.average.kiloBytesPerSecond | Average rate of transmitted traffic during the time interval. |
| Network Undersize Errors | net.errorUnderSize.delta.summation.number | Number of undersize errors detected over the network in the selected duration.<br>Undersize errors indicate bad frames generated by connected devices.<br>. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Network Xmit Errors | net.errorXmit.delta.summation.number | Number of transmit errors detected over the network in the selected duration.<br>Xmit errors occur when there is excess input rates of traffic, or if the transmit buffer is full.<br>To minimize the occurrence of this error, you must increase the speed of the interface and move the link partner to full-duplex. |
| Out Queue Length | net.outQLen.absolute.average.number | Number of output packets waiting in the queue. |
| Rx Broadcast Packets | net.broadcastRx.delta.summation.number | Number of broadcast packets received during the time interval. |
| Rx Broadcast Ratio (%) | net.broadcastByRx.ratio.average.percent | Percentage of broadcast packets received during the time interval. |
| Rx Jumbo Packets | net.jumboRx.delta.summation.number | Number of jumbo packets received during the time interval. |
| Rx Packet Drop Percent (%) | net.packetDropRx.ratio.average.percent | Average ratio of total number of dropped Rx packets to total number of Rx packets. |
| Rx Packet Errors | net.errorRx.delta.summation.number | Number of received packet errors detected over the network in the selected duration.<br>For packet-oriented interfaces, Rx packet error indicates the number of inbound packets that contained errors preventing them from being delivered to a higher-layer protocol.<br>For character-oriented or fixed-length interfaces, Rx packet error indicates the number of inbound transmission units that contained errors preventing them from being delivered to a higher-layer protocol. |
| Rx Packets | net.packetsRx.delta.summation.number | Number of packets received during the time interval. |
| Total Network Traffic | net.usage.delta.summation.kiloBytes | Sum of data transmitted and received during the time interval. |
| Tx Broadcast Packets | net.broadcastTx.delta.summation.number | Number of broadcast packets transmitted during the time interval. |
| Tx Broadcast Ratio | net.broadcastByTx.ratio.average.percent | Average percent of broadcast packets transmitted during the time interval. |
| Tx Jumbo Packets | net.jumboTx.delta.summation.number | Number of jumbo packets transmitted during the time interval. |
| Tx Packet Drop Percent | net.packetDropTx.ratio.average.percent | Ratio of total number of dropped Tx packets to total number of Tx packets. |
| Tx Packet Errors | net.errorTx.delta.summation.number | Number of transmitted packet errors detected over the network in the selected duration.<br>For packet-oriented interfaces, Tx packet errors indicate the number of outbound packets that were not transmitted because of errors.<br>For character-oriented or fixed-length interfaces, Tx packet errors indicate the number of outbound transmission units that were not transmitted because of errors. |

| Metric Name | Metric API Name | Description |
|---|---|---|
| Tx Packets | net.packetsTx.delta.summation.number | Number of packets transmitted during the time interval. |
| Unicast Rx Packets | net.unicastRx.delta.summation.number | Total number of unicast packets received during the time interval. |
| Unicast Tx Packets | net.unicastTx.delta.summation.number | Total number of unicast packets transmitted during the time interval. |
| Unknown Rx Packets | net.unknownRx.delta.summation.number | Total number of unknown packets received during the time interval.<br>For packet-oriented interfaces, unknown Rx packets indicate the number of packets received through the interface that were discarded because of an unknown protocol or an unsupported protocol.<br>For character-oriented or fixed-length interfaces that support protocol multiplexing, unknown Rx packets indicate the number of transmission units received through the interface that were discarded because of an unknown protocol or an unsupported protocol. |
| Total Rx Bytes | net.totalRx.delta.summation.bytes | Sum of bytes received during the time interval. |
| Total Tx Bytes | net.totalTx.delta.summation.bytes | Sum of bytes transmitted during the time interval. |
| uRPF Drop Packets | net.droppedRPFRx.delta.summation.number | Number of packets dropped due to unicast reverse-path forwarding (uRPF) |
| uRPF Packet Drop Ratio | net.droppedRPFRx.rate.average.percent | Average ratio of dropped uRPF packets to total Rx packets. |

## Switch Port Metrics

Switch port metrics provide information about the network performance of switch ports.

### Network Metrics

These metrics provide information about the network performance of the switch port.

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Average Egress Latency | net.latency.absolute.average.nanosecond | Average end-to-end latency of successful requests made to a switch port. | |
| Carrier Losses Detected | net.txcarrier.delta.summation.number | Number of transmitted packets that experienced loss of carriers per host port over a five minute interval.<br>This metric is captured only for the switch ports of NSX-T host transport nodes. | |

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Collisions Detected | net.txcolls.delta.summation.number | Number of transmitted packets that experienced Ethernet collisions on a host over a five minute interval. A non-zero value of this field indicates possibility of network congestion.<br>This metric is captured only for the switch ports of NSX-T host transport nodes. | |
| Discarded Rx Packets | net.discardedRx.delta.summation.number | Number of discarded inbound packets.<br>Packets are discarded to free up the buffer space. | |
| Discarded Tx Packets | net.discardedTx.delta.summation.number | Number of discarded outbound packets.<br>Packets are discarded to free up the buffer space. | |
| Dropped Rx Packets | net.droppedRx.delta.summation.number | Number of Rx packets dropped during the transmission interval. | Yes |
| Dropped Tx Packets | net.droppedTx.delta.summation.number | Number of Tx packets dropped during the transmission interval. | Yes |
| FCS Errors | net.errorFcs.delta.summation.number | Number of frames transmitted or received with a bad checksum (CRC value) in the Ethernet frame.<br>Frame check sequence (FCS) errors indicate the frames of data corrupted during transmission. These frames are dropped and not propagated to other ports. | |
| Giant Errors | net.errorGiants.delta.summation.number | Number of giant errors over the network during the selected duration. | |
| Host Latency Per pNIC (ms) | netopa.pnicLatency.absolute.average.microsecond | Time taken by the data to pass from one host pNIC on a network to another. | Yes |
| Interface Peak Buffer Utilization | net.peakBufferUtil.absolute.maximum.bytes | Peak buffer occupancy per switch port during the time interval. | |
| Interface Rx Utilization (%) | net.rx.utilization.absolute.latest.percent | Interface utilization percentage for the received traffic. | |
| Interface Status UP (ms) | net.interfaceStatus.delta.summation.millisecond | Interface uptime in milliseconds. | |
| Interface Tx Utilization (%) | net.tx.utilization.absolute.latest.percent | Interface utilization percentage for the transmitted traffic. | |
| Interface Utilization (%) | net.utilization.absolute.latest.percent | Interface utilization percentage for the transmitted and received traffic. | |

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Max Host Latency Per pNIC | netopa.pnicLatency.absolute.maximum.microsecond | Maximim time taken by the data to pass from one host pNIC on a network to another. | Yes |
| Max Network Traffic Rate (Kbps) | net.usage.rate.maximum.kiloBitsPerSecond | Maximum network usage rate on the switch port over any five minute interval in the selected duration. | |
| Max Network Tx Rate (Kbps) | net.transmitted.rate.maximum.kiloBitsPerSecond | Maximum network data transmission rate over any five minute interval in the selected duration. | |
| Max Packet Drop Ratio (%) | net.packetDrop.ratio.maximum.percent | Maximum five minute interval ratio of total dropped packets to total number of packets. | |
| Max Packet Drops | net.droppedTotal.delta.maximum.number | Maximum number of dropped packets over any five minute interval in the selected duration. | |
| Maximum Egress Latency | net.latency.absolute.maximum.nanosecond | Maximum end-to-end latency of successful requests made to a switch port. | |
| Maximum Total Network Rate (Kbps) | net.total.rate.maximum.kiloBitsPerSecond | Maximum network usage rate over any five minute interval in the selected duration. | |
| Min Host Latency Per pNIC (ms) | netopa.pnicLatency.absolute.minimum.microsecond | Minimum time taken by the data to pass from one host pNIC on a network to another. | |
| Minimum Egress Latency | net.latency.absolute.minimum.nanosecond | Minimum end-to-end latency of successful requests made to a switch port. | |
| Multicast Rx Packets | net.multicastRx.delta.summation.number | Number of multicast packets received in the selected duration. | |
| Multicast Tx Packets | net.multicastTx.delta.summation.number | Number of multicast packets transmitted in the selected duration. | |
| Network Align Errors | net.errorAlign.delta.summation.number | Number of alignment errors detected over the network in the selected duration.<br>Network alignment errors occur if a frame arrives with part of an octet missing, and having an FCS error. | |
| Network Carrier Sense Errors | net.errorCarrierSense.delta.summation.number | Number of carrier sense errors detected over the network in the selected duration. | |
| Network Deferred Tx Errors | net.errorDeferredTx.delta.summation.number | Number of deferred transmission errors detected over the network in the selected duration. | |

| Metric Name | Metric API Name | Description | Supported by Databus |
|---|---|---|---|
| Network Excessive Collision Errors | net.errorExcessiveCollisions.delta.summation.number | Number of excessive collision errors detected over the network in the selected duration. | |
| Network Late Collision Errors | net.errorLateCollisions.delta.summation.number | Number of late collision errors detected over the network in the selected duration. | |
| Network Long Frame Errors | net.errorFrameTooLongs.delta.summation.number | Number of network long frame errors detected over the network in the selected duration. | |
| Network Max Rx Rate (Kbps) | net.received.rate.maximum.kiloBitsPerSecond | Maximum rate at which the data is received during the time interval. | |
| Network Maximum Rx Rate (Kbps) | net.rx.rate.maximum.kiloBitsPerSecond | Maximum rate at which the data is received during the time interval. | |
| Network Maximum Tx Rate (Kbps) | net.tx.rate.maximum.kiloBitsPerSecond | Maximum rate at which the data is transmitted during the time interval. | |
| Network Multi Collision Errors | net.errorMultiCollisionFrames.delta.summation.number | Number of multi collision errors detected over the network in the selected duration. | |
| Network Packet Count | net.packetsTotal.delta.summation.number | Total number of packets transmitted and received from the switch port. | |
| Network Packet Drop Percent (%) | net.packetDrop.ratio.average.percent | Average ratio of total number of dropped packets to total number of packets. | |
